Across the Bay State in Pittsfield, **General Electric's Ordnance Division** of 3,500 employees is pushing development of *Polaris* inertial guidance and fire control under a multi-million dollar contract. This division also has an $8 million development contract for the huge *Talos* magazine, feeder and checkout systems to go aboard the nuclear cruiser Long Beach. The cruiser, incidentally, is being built by **Bethlehem Steel** at Quincy, Mass., under a $100 million contract. This shipyard also is commencing work on a $108 million nuclear frigate which will be armed with *Terrier* missiles.

GE is in the process of negotiating a $10 million follow-on for the *Talos* system and is working at Pittsfield on a $10 million *Atlas* tracker. Missile contracts in the division total over $50 million. At Lynn, Mass., GE is turning out engines for *Quail* decoy missiles and a complement of missile support equipment including leak detectors, electronic strip chart recorders, insulation test equipment, switchboard instruments and inertial systems components.

Looming large in the region's missile industry is **Avco,** which last month opened a $23 million research center at Wilmington, Mass. Holder of a $111 million contract for development of the *Titan* nose cone, Avco employs 1700 and is also deeply involved in shock wave research.

Just off Boston's "Golden Industrial Semicircle"—a congregation of companies along Route 128—**RCA** is producing miniaturized electronic missile controls and components in a spanking new $3 million plant. Other leaders of the area are **Sylvania Electric, CBS Electronic** and **Transistron.**

Recently this important new industrial area saw the formation of **Goodrich-High Voltage Astronautics Inc.** to research, develop and manufacture ion propulsion engines for space vehicles.

• **Connecticut supplies parts**—In a figurative sense, much of the work being done in Massachusetts is to supply the electronic "brains" for missile and space projects. By the same token, Connecticut is caught up in a big effort to provide "innards"—the hundreds of thousands of metal parts and subsystems.

Precisely how important missiles are to the Nutmeg State's economy is evident in a recent report of the Connecticut Development Commission. A survey by that agency shows 224 firms providing parts or services to prime and major subcontractors. These firms employ a total of 11,000—including 27,000 technical workers—but the precise percentage actually engrossed in missile work is not known.

However, it is believed to be substantial, even when stacked up against the state's total manufacturing work force of nearly 400,000. The CDC says 57 of the state's 169 cities and towns have missile operations underway.

In addition to parts, the state is showing a steady growth in missile electronics and related research.

At Groton last month, the George Washington, first nuclear fleet ballistic missile submarine which will fire its first **Lockheed** *Polaris* next year, slid down the ways at the **Electric Boat Division** of **General Dynamics Corp.** The sub cost $100 million and the company is working now on a sister ship, the Patrick Henry, and will soon start a third, the Ethan Allen. Employment at EB is up over 8000 and the company has scores of suppliers and subcontractors through the Northeast.

A few weeks ago the Office of Naval Research handed Electric Boat the managership of an industry-Navy team working on SUBIC (submarine integrated control system) aimed at reducing FBM sub crews from 100 to 12 men. Concept of the project is to create "balanced man-machine partnership" utilizing greater electronic sensing and data processing equipment and a television-type visual display of information.

Largest Connecticut missile employer is the **Pratt & Whitney Division** of **United Aircraft** at East Hartford. Many of the division's 35,000 employees are producing J-57 and J-52 engines for *Snark* and *Hound Dog.* **UA,s Hamilton Standard Division** at Windsor Locks with nearly 12,000 employees is producing *Nike* parts, secondary power packs, air conditioning systems, fuel controls, pneumatic valves and starters for other missile systems.

Other large companies with important missile assignments include **Kaman Aircraft,** Bloomfield, which is studying electronic countermeasures for *Polaris* missiles; **Landers, Frary & Clark,** New Britain, producing 2.75 rockets; **Naugatuck Chemical Division, U. S. Rubber Co.,** R&D solid propellant rocket liners; **Norden-Ketay,** Stamford, analog-to-digital converters for *Atlas;* **Lycoming Division of Avco,** Stratford, nose cones for *Nike-Hercules Polaris* rocket case compo *Talos* forward-sleeves and *Titan* bodies, cylinders and heat sinks.

A recently-issued CDC report 358 Connecticut firms employing 000 scientific and technical work research labs—nearly all inv electro-mechanical, metallurgical, ical and aerodynamic work, much related to missiles. Interestingly en Connecticut has one researche every 25 production workers.

• **New Hampshire**—Electroni the fastest growing industry in Hampshire, with employment numbering 8750—more than 10 the state's 83,000 total work More than 25% of the electronics duction is missile-oriented, chief the component field.

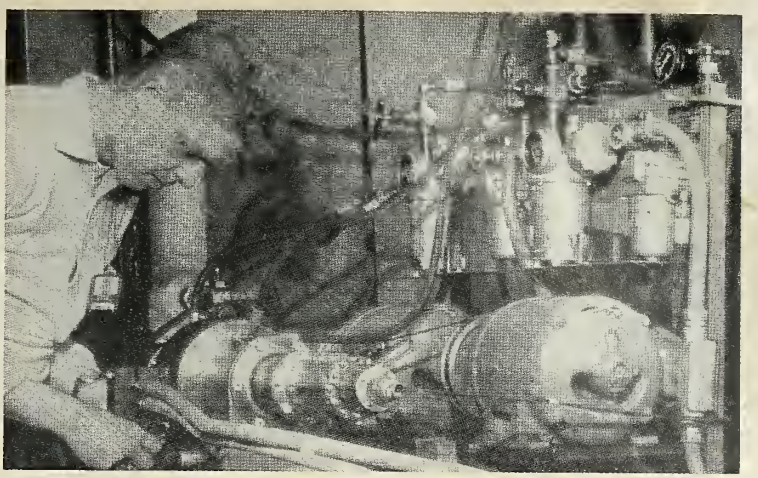
Leaders include **Sanders Assoc** Nashua, which started out with a dozen employees in 1945 and grown to around 1000. Sanders won a subcontract from **Bendix tion** to develop the guidance "se for *Eagle.*

Transistors and capacitors are produced at a **Sprague Electric** in Concord; **Sylvania,** with one sistor and diode plant at Hillsbo looking around the Granite Stat another plant location; **Rayth** Hookset facility is manufact power suppliers and transformers its other divisions.

At Manchester, precision resi are coming off the production lin **Tel-Labs Inc.** and in Concord, **Richard D. Brew Co.** is making lines. With an in-house-developed chine tool, **Ber-Kit Industries,** chester, is finding a profitable m market for precision screws.

A fourth FBM submarine, the Lincoln, is being constructed at P mouth Navy Shipyard.

State development officials re that employment is "tight" in Hampshire. As textiles have decli electronics have taken their place.



• **Vermont**—Across the state in Vermont, firms are busy suppl machine tools for the missile indu **IBM** has a large plant at Burlin making relays for data processing vices, and at Bennington **Sprague tric** is producing electronic com ents and ceramic sheathed wire.

• **Maine**—Only a few Maine f are turning out missile parts, acc ing to the state's Department of nomic Development. **Alloy Prod** Sanford, **Portland Machine Tool Maine Metal Finishing,** Gorham, the principal ones supplying spec items to various weapons contract

Interview With General Sessums

"He is the rare kind of commander who always seems to know exactly what everyone under him is doing . . . and regardless of how occupied he may be with important decisions, if he feels someone has done a good job, he always finds the time to put it in writing in the man's record."

The words were tinged with regret as they came from an officer the other day. For he was speaking unhappily about the retirement of his boss—lean, nimble-witted Maj. Gen. John W. Sessums, Jr., as vice commander of ARDC, a post he had held for the past five years.

Mechanical engineer-trained (University of Tennessee, Air Corps Engineer School) Johnny Sessums has been intimately associated with aircraft and, in recent years—missile—research and development throughout his 30-year career. And his firm guidance will be missed. In the early '30's while in the Canal Zone he flew—and crashed on its second flight—a homemade monoplane with an engine he had constructed from outboard motor parts. During World War II, he headed up the AF's Aircraft Production Division for three years then shipped overseas as chief of plans for the 22nd Tactical Air Command.

Returning in mid-1945 to the U.S., he promptly was made assistant to the chief of R&D at AMC, Dayton. Six years saw him rise to deputy commanding general of ARDC at Wright-Pa son AFB, and in 1954—to vice c mander of the entire ARDC comm Along the way, in addition to his w personality, silver-haired Johnny sums has earned the reputation mechanical genius. His associates he is "conscientious in everythin does."

ARDC Commander Lt. Gen. I ard M. Schriever noted Sessums one of the earliest advocates of listic missiles and called the ret general "a voice in the wilderne the late '40's and early '50's." A was in the process of stepping back civilian life last week, General Ses was invited by M/R editors to over the missile development hor

Q. The next 10 years hold promise of big things. Let's take ballistic missiles. We're pushing ahead with *Atlas* and *Titan*—the so-called first generation ICBM's—and in a few years will come solid-fueled *Minuteman*. What do you believe will be the third generation?

A. If I had to bet on it, I would say the pre-packaged liquids. And it is my firm belief that we are going to find the air-launched ballistic missile is really the pay-off.

Q. You mean strategically and from a cost standpoint, too?

A. Yes. The overall cost of defending the country can be greatly reduced with a system using CAMAL, the nuclear-powered, continuously airborne, missile-launching, low level airplane, and the ALBM. With a fleet of these planes, you would need only a few bases. The planes don't have to be accommodated on the ground all at one time—they stay in the air most of the time. On patrol, they could be a terrific deterrent. Not only can they get closer, which helps solve your targeting problem, but by getting closer the magnitude of the problem of detection and destruction reduces very rapidly. Such a force operating on a global basis would be able to strike at all enemy target complexes. It would be a most difficult task for any enemy to locate the constantly moving patrol. I think that with such a force it would be very difficult for any aggressor to launch a surprise attack on the U.S.

Q. Letting your imagination go a bit, how feasible is the CAMAL-ALBM as an anti-missile missile?

A. Of course, the CAMAL concept of operations is not defensive in nature, rather it is a weapon system designed to deter the enemy from launching his ICBM's. It is true that CAMAL would be able to assume tasks of a defensive nature because it will be a very versatile airplane capable of carrying very high payloads. We are talking now, for instance, of intercepting missiles at 18,000 miles an hour and 700 miles high. This is quite a problem—the defensive missile which may be going even faster than that will always have the disadvantage of taking off last. So, you can't assume you are going to get him half way; you are going to have to get him somewhere between half-way and home plate. CAMAL would put you out to where this half-way business becomes the ocean—instead of the U States.

Q. That certainly is desirable. would CAMAL have a capabili combatting a number of ICBM's ing in; a capability superior ground-based system?

A. The Kitty Hawk of the launched missile business is the mile type that we are developing The studies that were carried o **Martin, McDonald** and **Convair-l heed** in competition for the A contract indicate that an airplan CAMAL's size ought to be ab carry several.

Q. And the size can be expect diminish with future developmen

A. Certainly. With the first bomb, you may remember, we terrible time folding the thing int biggest airplane we had. Compar now to atomic artillery shells now can be shot from a gun. Yo expect increased efficiency in ALBM's propellants, which will r the size of the missile. So, you c we are either going to come do the size of the missile or be a shoot it further with a bigger if we keep it roughly at 10,000 p size.

Q. Visualizing an airplane out over the ocean hunting missiles, going to be a devilish compu problem. The airplane would computer.

A. You may be right; you ha a problem. But it seems to me th to lick it is by building your det in the plane. This would elimina need for the ground communi

rol system we have now, with s of large capacity computers and munication relays for detecting tracking. If you have the weapon oard and the detection equipment oard, all the computer does is put ignals in the missile, and the plane can fire instantaneously, assuming have the authority to launch. All need is a signal, like SAC now or the positive control system.

). It is still going to take a big air- to carry it all.

. Well, it is going to take a big ane to carry a nuclear reactor and ding. This is another point: you say if you have a fleet of these s patrolling the perimeter of an y country, they will just send their rs and shoot them all down. It is to be a long time before there are ic fighters—when you start out 60,000 to 100,000 pounds of ding before you start to fill in the e and the airplane. So, I would ne any counter weapon would be issile. It might be submarine- hed. But, if your CAMAL has rity to defend himself—take on gs—then I would think that as as a missile was launched at him, ould be able to get the missile whomever launched it.

. This looks like an interesting ect to tie in the Air Force early ing system, and possibly with the task of anti-submarine warfare.

. There are a great variety of pos- ies. And the thing that appeals is that it offers a chance to save money by reducing some of the weapons systems we have now, offensive and defensive.

. Of course, any saving with a a like this would be very far in ture. We would still have to go with ICBM base building, cost- n enormous amount.

. Yes. It is just like General Le- says. He will take any new n that is proven. This is true of and *Titan*. He's not about to take -52's off the line, until *Atlas* and have been proved. You have to them in the hands of trained and with a demonstrated capa- first. Target selection (planning of attack and all these things) o a factor and poses a much er problem than the average in- al realizes. The CAMAL airplane ew development—it hasn't been own yet. The ALBM is a new pment. It will be some time be- we get a really satisfactory air- ed ballistic missile. Before you ne built, you can see another is going to be a big improve-

On the point of training. In pinion, how many years will it be before we can muster a 15-minute ICBM retaliation system?

A. Well, the nucleus of the capability will start when the first *Atlas* becomes operational. That means crews have been checked out on the mechanism. But just having a group of men trained in the mechanics alone is not enough. You are going to have to build up all the accouterments—targeting is a problem we are learning more about every day. I would say soon after we kick off, we ought to have some capability. That capability should increase at a rapid rate as facilities and additional personnel become available.

Q. Let's switch over now to what's ahead in propellants and materials. On improving the specific impulse of solid fuels, what's the outlook on aluminized perchlorates?

A. They have shown considerable improvement—something like 20 per cent. I think we are going to see other additives that will be very effective. A great deal of research is going on in the boron field, both as a fundamental fuel and additives, which may produce even better results. We have gotten higher than 260 I_{sp} with solids. But with perchlorates, you must remember they are extremely sensitive and the higher specifics become, the more sensitive they get. This creates a problem in making them meet storage and handling requirements. If they are so sensitive that if anyone just tapped a rocket accidentally and it went off, it wouldn't have much military use.

Q. Where are you having heat problems with solids—just in the nozzle area?

A. In the nose cone, of course.

Q. How about the casement side?

A. Well, we aren't having any particular problem, other than trying to get the weight down.

Q. And with liquids?

A. The big problem here is the motor chamber pressure. A number of people are working on chambers of up to 1000 psi. And with this order of magnitude they are getting into entirely new developments to keep the engine from blowing up.

Q. Actually, most ARDC work is strictly related to materials. What are the goals in this area of an applied research nature?

A. Beryllium development is a good example of our applied research efforts. It is really a wonder metal, but it is very hard to extract from its ores and not too many exploitable sources have been discovered. Furthermore, we have brittleness and joining problems. Substitution of beryllium for steel has provided us with an extremely sensitive, light weight gyro. Many other specialized applications, such as brake systems, nose cones, satellite structures, are visualized which could reduce their weight by 50% or more.

Q. Has the toxicity problem been licked?

A. No, but the beryllium industry and the AEC over a period of years have developed many safeguards from which we and our contractors are learning.

Q. Are we trying to build an industry, like we did with titanium? Everyone knows how titanium slumped. Now, are we building up the beryllium effort at the expense of other important metals such as the refractories—like columbium—so all our eggs will be in a beryllium basket?

A. Not at all. We are also concentrating on applied research in the refractory metals. As for building an industry, you will recall that, initially, aluminum and magnesium were primarily aircraft materials. Both have become a boon to the civilian economy. I expect the same pattern for titanium. But money is always a problem. With the J57 Pratt & Whitney engine, there was a large premium for the titanium in it—so large a premium, in fact, that a decision was made at higher levels to cut the percentage of titanium to where it would cost only $150,000 or so premium over the price of the engine. It would have been fine if we could have afforded to create a terrific market for titanium.

Q. What about "whiskers?"

A. Research in "whiskers" is one of our longer-range programs. Such studies may shed new light on problems, such as fatigue, which have long plagued the Air Force. A string of iron molecules making up one of these "whiskers" is out of the ball park for anything we've known in the past for strength—over 2,000,000 psi, many times the strength of any known steel.

Q. What would you say will be the basic material for space vehicles of the foreseeable future?

A. Obviously, it is going to be a long time before we can grow molecules into sheet sizes. So, I think you will see stainless steel alloys, with their terrific strength properties, particularly in honeycombs, being used for quite some time. ARDC, of course, is investigating all approaches of the entire spectrum of basic materials. And you never know what will be coming up, because there are literally billions of possible combinations. In the high-temperature area, we are looking into the refractory metals, ceramics, and graphite and trying all types of cooling tricks —evaporative, porous, ceramic-coating and regenerative systems. Any of these could be a real answer if we come up with ways of improving their characteristics—either by alloying or protective coatings, or both.

Missile Aluminum Uses Increase

The lightweight workhorse of the aircraft industry proves to be a versatile metal for missiles, with support equipment offering the greatest market

by Paul Means

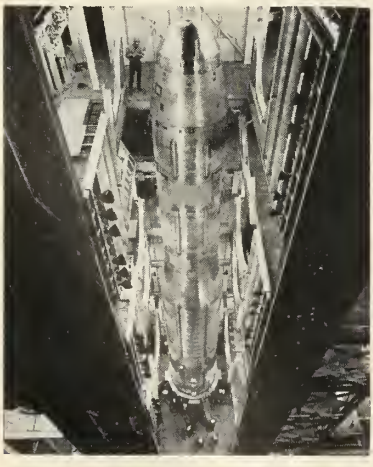
WASHINGTON—Aluminum, long the economical lightweight workhorse of the aircraft industry, is now proving to be one of the most versatile materials for missile and rocket development.

The metal is used in almost every type of missile component and support equipment—from solid propellants to warheads, from the largest missile hull to the tiniest electronic component. Aluminum parts carry, fuel, launch and track today's missiles and space vehicles.

Aluminum accounts for approximately 10% of the average missile's weight—second only to steel. The amount of aluminum used is increased in the newer missiles, and as missiles advance from the R&D stage to production.

With more and more missiles moving along the production line, a vast new market is opening up for the aluminum industry.

In 1958—the first year that missiles were produced in any quantity—the Department of Defense purchased 342,202,000 lbs. of aluminum, 24,451,000 lbs. of which were specifically designated for the A-2 missile program. In 1959, DOD expects to purchase 307,492,000 lbs. of aluminum, 19,199,000 lbs. of which are earmarked for missile use.



Much of the aluminum not specifically designated for missile development finds its way into missile checkout, ground support, tracking and electronic equipment. Also not included in the totals are National Aeronautics and Space Administration aluminum uses not specifically purchased from one of the services.

Expectations are that DOD and NASA aluminum purchases for missiles in 1960—when IRBM's, ICBM's, and space vehicles go into quantity production—will skyrocket, offsetting declining aluminum purchases for military aircraft.

The number of primary aluminum producers, which expanded from four to six in 1958, are: **Aluminum Company of America, The Anaconda Company, Harvey Aluminum Inc., Ka Aluminum & Chemical Corp., Or Corporation,** and **Reynolds Metals** The new producers were Harvey Ormet, which is jointly owned by **Mathieson Chemical Corp.** and **Re Copper & Brass Inc.**

In back of these companies over 26,000 firms—including most the major missile contractors—have the capability to fabricate aluminum into its desired forms.

• **Myriad applications**—A comp list of missile parts made wholly partly out of aluminum would be most impossible to compile. A par list would include: light and he gauge sheets for hull and nose co ponents; rod, bar, wire, and sc machine stock for electronic con and guidance units; angles or extru shapes for internal bracing; foil in el trical components; forgings for fi honeycomb aluminum for wing tail assemblies; powder for ignition s tems and solid propellants; and alu num in many forms for brackets, f tanks, motor heads, rocket motor tub

ALCOA integrally stiffened, extruded aluminum plate forms the *Titan's* hull.

Representative Uses of Aluminum in Missiles

MISSILE	WHERE ALUMINUM IS USED	OVERALL WT.—LBS. (Takeoff)	WT. OF ALUMIN USED—LBS.
AEROBEE-HI	nose	231	100
ATLAS	powerplant	200,000	3500
BOMARC	hull, skin, wings, tailskin, fuel tanks, motor components	8500	1500

-propellant core molds; and spin chers for satellite launchers and e probes.

Aluminum uses in support equipment include: shipping containers, ries for loading and unloading; way carriers, field loaders and car-; field liquid oxygen producers; ge units and trailers; lightweight r generators, launching towers, devices, photomapping vans, ing radars, acquisition radars, ronic control vans, fire control pment, and even portable field ers for personnel.

t is in the latter area—missile support equipment—that aluminum companies feel they have their greatest existing market.

Two of the most attractive qualities aluminum are its weight, of course, its cost.

Aluminum has a specific gravity of 7 (one third the volume of steel). ght savings in structure allow for weight in propellants and payAluminum also has a great variety of uses, requires little maintenance, resists corrosion, is non-toxic, has a tensile strength of 13,000 per square inch—a factor which be raised to 90,000 lbs. per square with alloys and special heat treats.

Low cost gains attraction—Aluminum's economy as a structural metal comes important when the missile is duced in volume. Prototypes are ly handicrafted and time and labor utshadow material costs. Materials is stage are not necessarily picked economy.

ut as missiles move into full-scale duction, time and labor costs drop, the proportion of materials cost to overall cost goes up. It is then that inum's low basic price, easy mability, and light weight will recommend its use wherever possible to cut unit costs.

And the price of aluminum has been lowered somewhat in recent years by improved methods and foreign competition. It presently sells for about 24.7 cents a pound.

Another advantage of aluminum is that it is in plentiful supply. Major expansion has taken place in recent years in primary aluminum production facilities. This was done partly by the producers to meet expanding demands of commercial and industrial aluminum users, and partly with guarantees from the government to meet military requirements.

The Federal government gave contracts to the aluminum producers after the beginning of the Korean War to expand aluminum facilities under which the government, for a period of 5 to 6 years following initial production from the facility, is required to purchase metal from the new facilities which the producer is unable to use or market in its normal operations.

• **Capacity swells**—The capacity for producing primary aluminum more than doubled between 1950 and 1958. Additional capacity of 433,000 tons was installed in 1958, representing a 24% increase during that single year.

New facilities installed during 1958 included Kaiser's hot-line at Ravenswood, West Va., the installation of two 16 million-pound plate stretchers, one by Alcoa and one by Reynolds, and a 6000-ton extrusion press installed for the Navy at their Hannibal, Ohio, plant by Reynolds.

Major facilities to be installed during 1959 include Olin Mathieson's new rolling mill at Hannibal, Kaiser's 30 million-pound plate stretcher at Ravenswood, and Alcoa's 14,000-ton press at its Lafayette, Ind., plant.

One drawback of aluminum for missile use is its comparatively low heat resistance. The metal melts at 1220°F, and begins to suffer measurable loss of strength above 400°F.

Though other metals and alloys have a higher heat resistance, very few can withstand surface temperatures created at very high Mach numbers for any length of time.

Much of this problem has been overcome by research into the effects of high temperatures for short periods on aluminum, and with newer missile designs and flight paths.

Almost every major form in which aluminum is available is used in missiles and missile support equipment: sheet, plate, castings, extrusions, forgings, rod, bar and wire, electrical conductors, insulated wire, foil and powder.

And the fabrication of aluminum in these various forms for complex forced aluminum fabrication companies to devise new special handling techniques and very careful quality controls.

• **Tight controls**—An example of this is the extreme tolerances that Reynolds must meet in fabricating the aluminum shells for *Redstone* and *Jupiter-C*.

To insure quality, Reynolds, which has been fabricating missile hulls since 1952, employs one inspector for every four technicians working on rocket casings. Each of the more than 20,000 parts, and each stage of assembly, is checked before joining.

Quality control starts for Reynolds, as it does for the other aluminum producers, when the aluminum sheet and plate is produced for missile parts. The metal must be perfect, devoid of scratches and blemishes. Electronic instruments search for possible weak spots that might fail under pressure. Width and thickness of the sheets and plates are measured to tolerances within a few thousandths of an inch, and samples are chemically analyzed.

The sheets are then taped to protect the surface from dirt, scratches, and fingerprints. This tape is not removed until the final assembly is ready for cleaning and finishing.

Reynolds then trims the aluminum sheets to their required length of 220 inches fitting a tolerance of 0.002 inches.

The trimmed sheet is then rolled to form a cylinder, then the ends are welded. Next, the shell is strengthened by spotwelding an aluminum reinforcing bar along the longitudinal weld.

Then the shell is trimmed to exact length, fitting a tolerance of plus or minus 0.015 inches. Aluminum stiffener rings, shaped on a radial draw forming machine, are spotwelded into the shell. There are approximately 24,000 spotwelds on a *Redstone* shell. The shells

SE	WHERE ALUMINUM IS USED	OVERALL WT.—LBS. (Takeoff)	WT. OF ALUMINUM USED—LBS.
KHERCULES	skin, bulkhead, fins, fittings	2000 (without warhead)	750

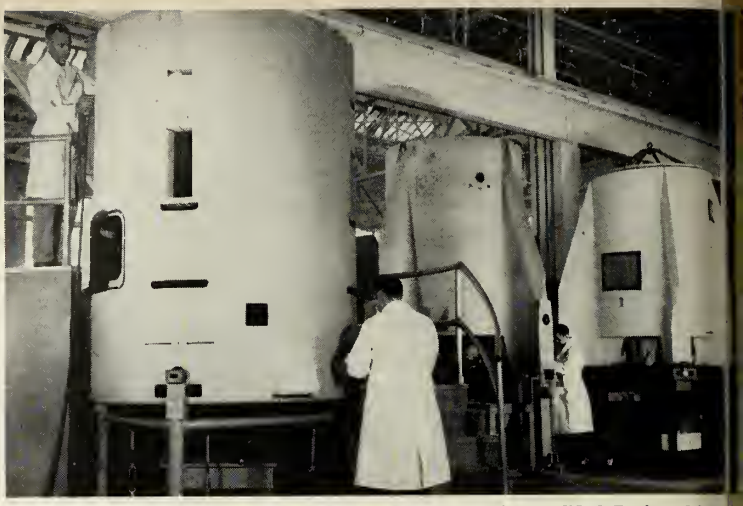
Source: Kaiser Aluminum & Chemical Co.

are then welded into sections, which require tolerances of 0.031 for a 34-foot section.

After the sections with the bulkheads are welded together, with X-rays checking the welds and extremely high tolerances demanded throughout, the piping and tanks are hydrostatically tested for leakage, pressurized to make sure the metal and welds withstand pressure, and optically inspected by instruments to check alignment of all assemblies.

These rigid quality controls follow the shell through final finishing for delivery to **Chrysler Corp.,** the prime contractor.



Other large missiles using aluminum plate or sheet as their frame and covering include *Thor, Jupiter, Titan, Snark, Bomarc, Polaris* and *Minuteman.*

•**Milling and aging**—The *Titan* uses integrally stiffened, extruded plate produced by Alcoa's 14,000-ton press at Lafayette. The 20-foot shapes emerge as inverted vee's. They are flattened into 34-inch widths, and shipped to **The Martin Co.,** at Denver for stretch-forming, chemical milling and welding. Mechanical milling reduces the skin to a uniform thickness. The two faces of the aluminum skins are milled to required dimensional tolerances including the flat surface of the web between the ribs.

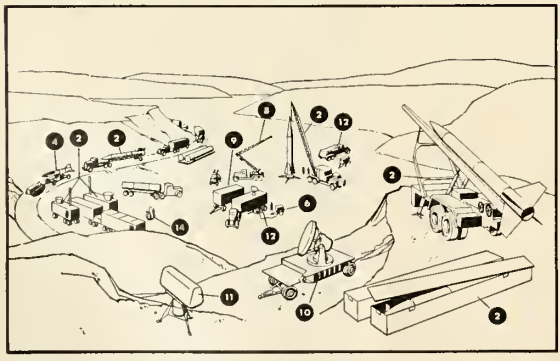
After inspection, they are stretch-formed in sections as large as 5 feet wide and 24 feet long, inspected for contour, and aged for final strength. Heat treating to a final T-6 condition follows and after additional aging, the panels are finally chemically milled.

Alcoa Aluminum plate is used for *Thor* and aluminum sheet is used for *Jupiter.*

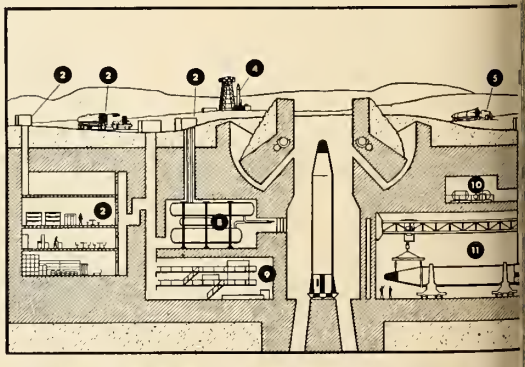
Smaller missile shells can be made of a single precision aluminum cold forging as **Hunter Douglas, Division of Bridgeport Brass Co.,** does for the *Sidewinder* motortube. This tube is typically straight within .020 inches, its inside diameter within .006 inches, wall thickness within .0015 inches. It has a yield strength of 72,000 psi minimum.

REYNOLDS fabricates the aluminum tail sections for the modified Project *Merc* *Redstone* scheduled to take the first American on a ballistic rocket flight.

• **Use in solids**—Another not too widely known application of aluminum in the missile industry is as a component in solid-fuel systems.



Polaris' solid-fuel motor, for example, uses a composite fuel made up of very fine aluminum powder in combination with conventional polymer bondings. The fuel is encased in aluminum firing chambers to increase the heat.



Powdered aluminum constitutes 15% of the propellant by weight used in the Army's *Hawk.*

• **Promise in support**—But according to a recent study by Kaiser, missile support equipment offers small and medium-sized aluminum f cators their greatest opportunity. the case of tactical missiles, alumi will gain widespread application cause of the entire missile bat must be readily portable and, in cases, capable of being airborne.

Aluminum's light weight, dur ity, and ease of maintenance in storage make it a favored metal t used in ground transport equipn designed to take the missile not from factory to test or installation but also from base to base as assig

Small missiles make wide use aluminum containers for shipm The *Sidewinder* is shipped in aluminum container 18 inches sq by 35 inches long. The *Falcon* shipped in an aluminum case measures 88 inches overall. The to-surface torpedo *Petrel* uses an minum case that telescopes into a for reshipment.

SUPPORT equipment aluminum uses include: 1—shipping container; 2—gantry; 3—highway carrier; 4—special loader, carrier; 5—LOX producer, storage and trailer; 6—power generators; 7—launch tower; 8—firing device; 9—photomap van; 10 & 11—track and acquisition radar; 12—electronic control van; 13—fire control equipment; 14—field showers. Fixed base uses clude: 1 & 6—personnel access; 2, 3 & 8—fuel transport, int and storage; 4—static testing; 5—missile transport; 7—quar and storage; 9—control room; 10—power generation; 1 warhead loading. A Bright Future for Cryogenics

Their advantages should enable them to stand off challenges of exotic systems at least until 1970

by Frank G. McGuire

Los Angeles—The outlook for cryogenics? Bright and clear. That's the opinion of propulsion experts, and they make a convincing argument to support their optimism. Despite the approach of nuclear rockets, ion and photon systems, and other exotic propulsion devices, it seems the chemical systems will be with us for a long time.

Part of the key to the future of cryogenic propellants lies in the definition of the term, from a scientist's point of view: "As they exist in a normal atmosphere on earth, cryogenics are liquified gases whose boiling point is considerably below vapor pressure at ambient temperatures . . . and which must be refrigerated in order to be stored under normal conditions." Storable propellants, on the other hand, do not have the characteristic of boiling off in a normal atmosphere on earth.

The significant words in both cases are "on earth." According to Robert S. Kraemer, group leader in **Rocketdyne's** preliminary analysis department: "When we get out into space, the environment is completely different, and we find that what is 'storable' in space is not 'storable' on earth."

This environmental difference eliminates (or greatly reduces) a major disadvantage of cryogenics and adds a handicap to the storables. The low-temperature nature of such high-performance propellants as LOX (–297°F), ozone (–169.5°F), liquid hydrogen (–423°F), and fluorine (–306.3°F), must, may lend itself very well to making these chemicals storable in space. Propellant combinations with higher, non-cryogenic boiling points, such as nitrogen tetroxide and hydrazine, will have great usefulness in immediate-retaliation missiles, but will not dominate the space flight field and may even yield to cryogenics in some missiles.

(There is evidence that almost anything will boil off in space—even solid propellants and possibly metals. It has been felt necessary to place a diaphragm over the exit nozzle of solid-propellant rockets that will coast for a long time in space, to prevent excess vaporization of the material.)

● **Stressing insulation**—Despite low temperatures in space, it will be necessary to insulate cryogenic propellents against direct solar radiation to prevent boil-off, and to insulate storable propellants to prevent freezing. Either boil-off or freezing would abort a mission. One method, proposed by Rocketdyne, features the use of lightweight plastic foam which acts both as insulation and as a load-bearing structure. The fluorine/hydrogen tanks in Rocketdyne's suggested space vehicle are mounted directly in the rigid foam, which insulates the tanks and provides support for the vehicle's outer walls. (The outer walls will be painted with a reflective coating to minimize solar radiation effects.)

To reverse the insulating action, the foam "umbrella" that protects the propellants from solar heat is rearranged to provide a reflecting surface to focus solar heat on tanks containing storable propellants to prevent freezing. It was calculated that just about as much insulating foam would be needed to prevent storables from freezing as to keep cryogenics from boiling off. The difference is merely in the design of the foam shield around the tanks. As a result, fuels and oxidizers formerly thought too touchy for space flight—such as fluorine and hydrogen—are just as storable for space missions as nitrogen tetroxide and hydrazine.

The new insulating powder recently developed for propellant tanks was not used in the Rocketdyne design because of the need for structural strength to support the vehicle walls. Actually, slightly larger amount of foam is needed for cryogenics than for storables, but the amount is "negligible," according to Rocketdyne.

● **Looking away**—A further step taken to control solar absorption by space vehicles is the technique of orienting the vehicle so that it presents as small a surface as possible to the Sun. While the vehicle is pointed nose-first at the sun, reflectors are extended from the sides at the nose to form a shaded area over the propellant tank area. Known as making the vehicle "solar statically stable," the technique is an easy one to carry out and involves keeping the solar-pressure-center aft of the center-of-mass. This method keeps heat away from the cryogenic-propellant tanks. When the reflectors are extended from the sides at the tail, they focus heat onto storable-propellant tanks to prevent freezing.

The Linde Company, manufacturer of cryogenic liquids, also has considerable confidence in the future of cryogenics as rocket propellants. According to C. T. Fallon, manager of cryogenic engineering, the firm expects to begin operation of its liquid hydrogen plant at Torrance, Calif., about April of 1960. This facility is designed to produce over 360,000 pounds of liquid hydrogen per month, 300,000 pounds of which goes to NASA under option. Linde will then truck the propellant to NASA's facilities for use in various programs.

● **Gains in storability**—The new insulations presently being developed, notably Linde's SI-4, assure almost complete storability of cryogenics. Although few details on SI-4 (Super-Insulation #4) have been released by the company because of pending patent proceedings, its weight and thermal conductivity have been announced. Compared with other standard insulations, SI-4 stacks up as follows:

Santocel thermal conductivity is between room temperature and 90°K, recorded as BTU/Hour-Foot-°F. This

'Specific Impulse Is King!' . . .

reads as 120 x 10^{-5}. Perlite, another standard insulation, has a thermal conductivity of 90 x 10^{-5}. This compares with a straight vacuum, which has a rating of 78 x 10^{-5} (with highly polished surfaces).

The SI-4 insulation rates at 3 x 10^{-5} in thermal conductivity, an obvious improvement of 30 times over Perlite, and 25 times over a vacuum. It weighs about 6.8 pounds per cubic foot, compared with the 8-pound-per-cubic-foot weight of Perlite. The figures established by Linde laboratories have been verified by the National Bureau of Standards.

Evaporation losses have also been considerably reduced by SI-4, and in the case of liquid hydrogen protected by the material, amount to 9.3% per year. Normal tankage using Perlite would lose about 200% per year. A LOX tank protected by SI-4 could be expected to lose 2½% to 3% per year through boil-off. The difference is due to the lower boiling point of hydrogen.

The cost of the SI-4 depends not only on production and availability, but also on the technique of application, which is very important. It would however, be a premium product, somewhat more expensive than Perlite. It would unquestionably pay its own way where the colder cryogenics are concerned, such as hydrogen or helium, but the low cost at which liquid oxygen and nitrogen are distributed make it questionable whether the premium cost would be justified in a ground installation. In an airborne vehicle, however, SI-4 has distinct advantages because of its light weight.

• **Limits of fluorine**—Linde feels that with the high specific impulse of a fluorine/hydrogen system combined with the storability of such cold fluids now possible, there is no great barrier to their use in space vehicles. However, when asked if they thought fluorine would ever be able to compete economically with liquid oxygen, company officials thought not. Agreeing with Rocketdyne spokesmen, they said fluorine would probably be used where specific impulse is the prime factor, but that it is very unlikely that fluorine would get down to the neighborhood of LOX in price-per-pound.

Until the advent of systems with higher specific impulses, there seems an excellent possibility that a cryogenic fluorine/hydrogen system will be the workhorse of our space programs where large payloads are used.

• **Comparisons**—The future of cryogenics in space flight as compared with other propulsion systems has been studied by Rocketdyne, which came up with some interesting results. Starting from a common point, that is, takeoff from a 300-mile orbit around the earth at a gross weight of 25,000 pounds, each vehicle or system was to complete a simulated mission to Mars. Payload delivered to Mars was the determining factor of usefulness.

The solid-propellant system delivered a gross payload of 1600 pounds, exclusive of any propulsion system or related items. Such a vehicle would be available in the early 1960's and a "fairly optimistic" solid propellant was assumed. In addition, higher motor-case strengths were assumed than those of other systems, and more staging was used.

In spite of this, says Rocketdyne, both the storable systems (hydrazine/nitrogen tetroxide bi-propellant liquid rocket) and the hybrid system (liquid chlorine - trifluoride/solid lithium - hydride) came out considerably higher in payload capability—about 2800 pounds, compared with the 1600 pounds for the solids. The pure liquid system (liquid fluorine/hydrogen) outperformed all the previous systems with a gross payload capability of 4000 pounds.

• **King Cryogenic**—"Regardless of complications," said Rocketdyne's Kraemer, "we found that higher specific impulse would always pay for itself . . . you might say 'Specific Impulse is King!' "

This criteria therefore establishes cryogenic liquids as the most efficient system for a number of years to come. Even with the advent of nuclear and ion rockets in the late 1960's or early 1970's, there will be a need for efficient large chemical boosters to get these low-thrust or radioactive rockets off the ground and away from earth.

The fluorine/hydrogen system will be available in the early 1960's, as will the large solid-propellant system, and other large cryogenic-chemical systems will be on hand even sooner. Advanced nuclear systems expected to be ready for flight by 1970 will bring the payload capability up to 6300 pounds, from the 4000-pound-capability obtainable with the F_2/H_2 system (still using the basic premise of a 25,000-pound-gross-weight vehicle leaving a 300-mile orbit). These advanced nuclear systems have a design I_s of 1080 seconds.

The future of one particular cr genic propellant—liquid oxygen— been questioned because of the po bility that liquid fluorine or oz might completely displace it. The u mate theoretical cryogenic combi tion is ozone/hydrogen, but ozone not yet reached the state of devel ment that allows its use as a stand propellant.

The ultimate practical combinati therefore, is fluorine/hydrogen, witl specific impulse of 398 seconds (th retical maximum specific impulse, lb-sec/lb. frozen equilibrium). Liq oxygen/hydrogen holds a spot ab ten seconds behind at 388 secon With the extremely low cost of L (less than a penny per pound) and high availability, it is an excellent for use in many vehicles where extreme performance of fluorine is mandatory.

• **Trend toward simplicity**—Spec equipment for handling LOX is of greater complexity (and in some ca less) than equipment for other cr genics. Rocket engines show a c tinuing trend toward simplification . witness the engine used in *Th Jupiter*: components reduced from in 1955 to 5 by 1960.

The turbopump problem is s to be greatly exaggerated, with b **Aerojet-General Corporation** and Ro etdyne defending it against advoca of pressurized systems. The reliabi of tubopumps in cryogenic systems much better than generally believ both companies say, and they emp size that the added structural weight a pressurized propellant tank is a mu greater penalty than the questiona gain from elimination of the turb pump system.

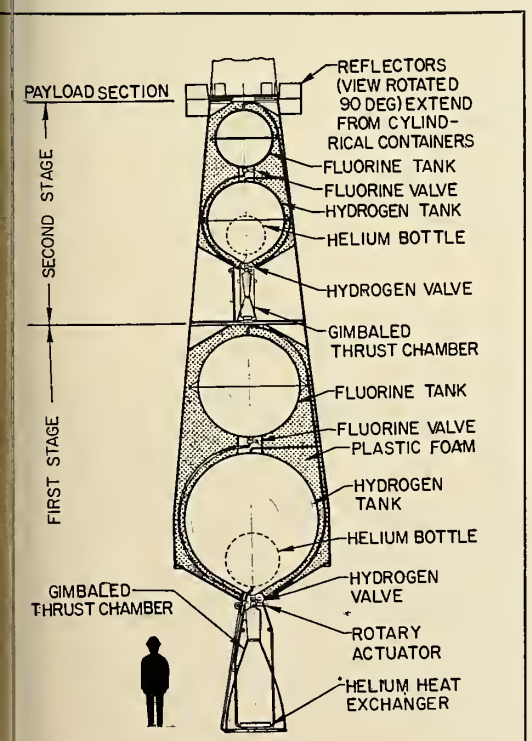
In upper stages that operate extreme altitudes, it is possible—a sometimes desirable—to almost co pletely eliminate moving parts, but it claimed there is no valid reason removal of turbopumps from boos stages. Even with the near-absolu zero temperatures of liquid hydrog (−423°F) there should be no probl of reliability with pumps and valves the equipment is properly designed.

• **Pleasing figures**—The cost propellants is a major factor in t large booster systems now in the desi stage. With the $900/pound price t on the cesium propellant of an i rocket in mind, it is nice to note t 10¢/pound cost of LOX/RP1, or t storable combinations at 70¢/pou or even the solid propellants that r up to $3/pound. These figures take a tremendous significance when o considers the three million pounds propellant that will be used in just t first stage of the *Nova* vehicle of

ion-pounds thrust, for example. For these reasons, economy, performance, availability and relative simplicity of handling, LOX takes a back seat to almost no other propellant. Where the utmost I_{sp} is needed, or where density is a consideration, Fluorine will be used. (It is about one-and-a-half again as dense as LOX.) When economy is the prime factor, LOX/Hydrogen will hold its own. As noted previously, the insulation problem with cryogenics varies with the environment, and appears to be an almost minor problem.

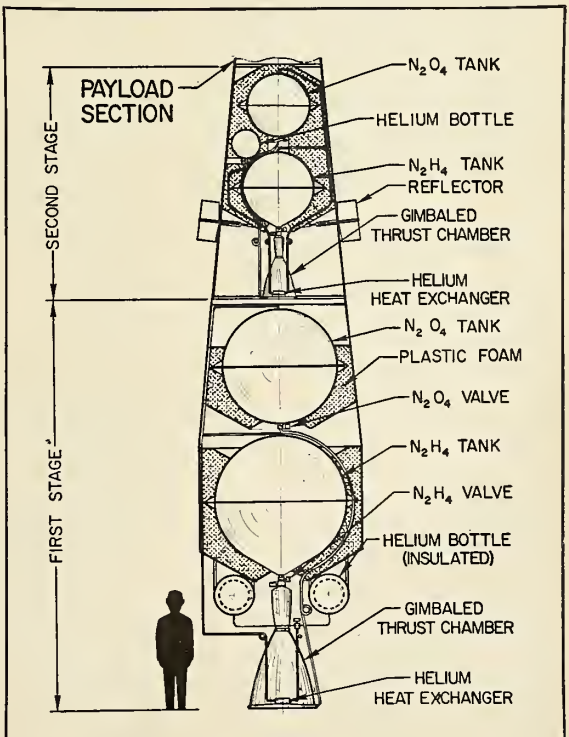
Interplanetary travel possibilities with LOX and other cryogenics varies with the area to be covered. In terrestrial space and closer to the Sun (Venus, Mercury areas) there is a telling definition of the storability of propellants, and the scale tends to shift toward those propellants with a fairly high boiling point. Therefore, in the region of earth and the Sun, cryogenics are not going to show up to their best advantage in long-term storability, but it is just a question of a few days or, on the moon, there is no real problem with cryogenics.

The feasibility, of course, depends on the length of time required before return to earth. The lunar temperatures during the night would aid in the storage of cryogenics while daytime temperatures would hinder storage. Once a vehicle leaves earth's environment, however, the scale pretty nearly evens out among cryogenics, storables and solids, because of the insulation needed for all of them.



• **Backing and filling**—Evidence has been seen lately that various planning agencies like the theoretical performance of a new propellant combination and try to work it into a program. Once a closer look is taken, however, at things like costs, availability, handling characteristics, etc., a slow backward movement is begun that results in a final choice like LOX/RP1 to fill the requirement. Even though faith in the storables is expected to be borne out by increases in specific impulse to 400 seconds at high altitudes, the cryogenics are likely to be at 460 seconds by the same time.

It has "disturbed" some liquid-propellant experts to see that the government has established research funds for the advancement of solid-propellant chemistry, but has not established any funds for development of storable liquid propellants. The potential of these non-cryogenic liquids has been demonstrated on a small scale, they note, and all that remains to be done is to develop them for full-scale operation.



Combustion-wise, there is a greater efficiency in cryogenics than in other propellants. Smoother and more stable combustion results from cryogenically-liquified gases; the best being two cryogenics, next best is a cryogenic and a non-cryogenic liquid, then two non-cryogenic liquids, and so on down into the more stable states. The more easily vaporized the gas, the easier it is to achieve and maintain a smooth, stable combustion.

So, although ozone/hydrogen is ultimate, it is not practical and fluorine/hydrogen takes over. But this is expensive and requires special handling, and so reverts to economical, available, high performance LOX/Hydrogen, which has no radioactivity, toxicity or other highly undesirable characteristics.

In the final analysis, therefore, we find that large payloads will be necessary in order to carry out significant space missions, but that they can be put into orbit most efficiently by a cryogenic combination of fuels—the specific choice depending on a number of factors. This situation will probably remain unchanged until at least 1970.

LORINE/HYDROGEN propulsion system depicted by ketdyne. Spokesmen see it as the space program workhorse.

STORABLE PROPELLANT space propulsion system, also as pictured by Rocketdyne. Near-complete storability is at hand.

Nike-Zeus Decision Is Looming

Slated to cost $1.5 to 2 billion in FY '61 alone, the nation's only anti-missile missile under development could be cut back

by James Baar

. . . Thunderer Zeus, who all dominion hath.—The Odyssey

WASHINGTON—*Nike-Zeus*—the nation's only anti-missile missile under development—faces a life or death crisis within the next six months.

Billions of dollars and the future strategic posture of the United States ride on the outcome.

In simplest terms, the Eisenhower Administration in its final days must answer this two-part question:

Shall the **Western Electric** *Zeus* system be put into production so that it can become operational on schedule in 1963?

Or:

Shall the billions that it will cost be spent elsewhere—if at all?

There is also a third possible choice: The Administration can temporize.

The price tag on this question for FY 1961 alone is about $1.5 to 2 billion. The total price for *Zeus*—all payable within the next few years—is almost anywhere from about $5 billion up. It depends on how much defense you want to buy.

To appreciate the awesomeness and complexity of the problem you should begin by bearing in mind three basic facts:

• The United States today does not have any defense against an attack by Russian ICBM's.

• *Zeus*, for better or worse, is the only foreseeable defense that the United States can have against ICBM's for at least the next eight to 10 years.

• Russia is expected to have enough ICBM's for a major attack beginning about 1962. And that capability is expected to mount rapidly thereafter.

• **Family resemblance**—Now, let's look at *Zeus*, itself.

Basically, it is a huge direct decendant of the Western Electric *Nike* family of anti-aircraft missiles—the *Ajax* and *Hercules*. It was designed from the same general concepts: command guidance, acquisition radar, ground battery computers. And it bears a strikingly similar appearance. However, the advances have been tremendous.

Zeus has three solid-propellant stages. The **Thiokol** booster engine, which has a 450-thousand pound thrust, delivers its power in about four and a half seconds. The **Grand Central Rocket** second-stage engine is powered by what the Army describes as "special high-energy propellants." It has a newly-developed plastic nozzle made by **Douglas Aircraft.**

Both the first and second-stage engines have been static fired successfully. The first-stage engine was first fired at Redstone Arsenal last August; the second-stage engine at Beaumont, Calif., this spring.

The *Zeus* system has huge radars and computers designed to find and track oncoming warheads and direct missiles to the right areas for interception within minutes. In the final seconds of flight, a precise tracker guides the *Zeus* to its target.

Major system components are scheduled to be tested later this year at the White Sands Test Range.

• **Funding history**—The Army, Western Electric and **Bell Telephone Laboratory** began studies on the system in the mid-1950's. In Jan of 1958 the Pentagon directed Army to proceed with the progra an urgent basis and scratched the s what similar **Convair** *Wizard* that being developed for the Air F However, the Pentagon directed Air Force to proceed with rapid d opment of BMEWS—the ballistic sile early warning system.

So far, well over a half-million lars has been spent on *Zeus*. than 80 companies are engaged i development in 17 states from York to California.

This brings us down to the pr slugging match over money for in the FY 1960 budget.

Originally, the Army recomme putting $1,003,000,000 in the b for *Zeus*. This included about million for R&D and more than million for tooling and other pr tion facilities as well as some for *Zeus* bases.

Later the Army reduced its request to $626 million—$300 m for R&D, the rest for production ties. But this figure also was una table to the budget-minded Adm tration. Only $300 million for R& mained in the Army budget by the it reached Congress.

The net effect of this would been a sizeable delay in the *Zeus* table. As one Army source put it: production money is needed for lead time items. When you pr dinner, the roast takes just so lo cook. If you delay putting it i oven, the whole meal is delayed

• **Change of mind**—The Adm tration explaination was that it did not feel *Zeus* was advanced en for production. However, as the

Part One of a two-part series on anti-missile missiles.

n-fighting in congressional committee passed, the Administration re- ed itself. It included an extra $137 ion for *Zeus* production facilities he so-called "master plan" for anti- raft defense.

The $137 million is conceded gen- ly to be just barely enough to keep *s* on schedule. It also leaves the nistration with the painful decis- to be made all over again in the ing months as the nation heads a presidential election year. Only time the sums involved are billions ead of millions.

At the very core of the problem is question of just how good *Zeus* rmy experts will tell you fervently: y good. A number of other Penta- experts will tell you: Yes—and no. h in a sense are correct. It's a mat- of premise: What do you want an -missile missile to do?

Of course, you want it to knock n ICBM's. But how many? And re? And at what cost?

• **Half a loaf**—Ideally the answers simple. You want an AICBM that knock down all ICBM's fired at in anger—even when the sky is ded with possibly dozens of war- ds and scores of decoys. All of this vity is to take place outside the osphere where explosives of multi- aton warheads will do relatively e damage. And the whole show ld cost about $1.98.

This isn't *Zeus*. Nor is it anything known to be feasible at this time.

The Army contends—and most ob- ive experts agree—that *Zeus* will able to provide adequate spot de- e of vital targets.

This means that if a dozen or so heads or warheads and decoys are led at a particular target—say a . ICBM base—*Zeus* will be capable preventing the target from being royed.

Very good. However, here comes rub. In the case of a city like New York or Chicago, *Zeus* might also make a perfect score. But some of the interceptions might take place not far overhead causing widespread fires. And if *Zeus* were to bat down nine out of 10 ICBM's, one five megaton warhead on Chicago would be enough.

Finally, *Zeus* will be able to do some discriminating between warheads and decoys. And the Army contends the system is sufficiently flexible so that even if Russia becomes capable of filling the sky with warheads and decoys, *Zeus* will become capable of dealing with the problem. However, this contention is open to argument outside the Army.

Obviously all of this adds up to a weapon that is not the ideal anti-missile missile. But the Army contends that to reject it on those grounds is like starving to death because the only food in the house is ham sandwiches and you want pressed duck.

• **Strong points**—Moreover, these arguments weigh heavily in *Zeus'* favor:

• No matter how powerful a deterrent force the United States can build, the nation is powerless to prevent an ICBM attack once a war begins unless it has some anti-missile missile system.

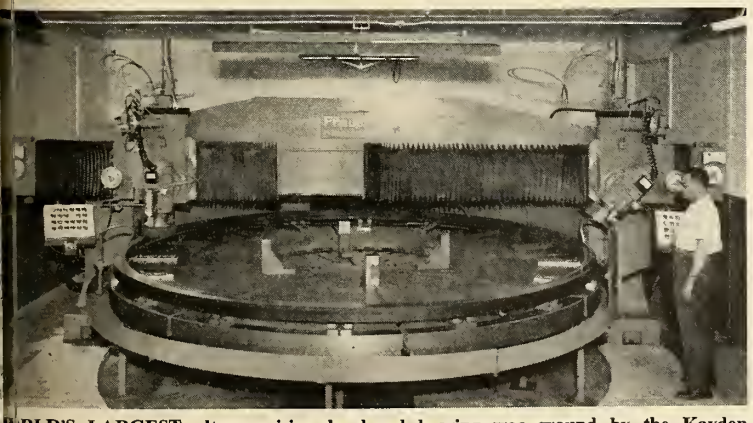
• At a very minimum, *Zeus* would provide a guarantee that a significant part of America's retaliatory force could not be destroyed on the ground by a surprise attack.

• The very existence of *Zeus* increases the cost of an attack for Russia and raises one more doubt as to whether one could succeed.

• Finally, if the United States were to scratch *Zeus* and put its cost into offensive weapons such as more ICBM's, how much better off would the United States be if Russia developed an AICBM like *Zeus*?

"Put it this way," one Army spokesman said. "No defense is perfect. If the enemy wants to get through badly enough, he always can by paying the price of admission. What we're doing with *Zeus* is boosting the price of admission."

• **Trouble ahead**—It is difficult for many to conclude other than that the *Zeus* program should be pushed ahead on schedule. However, powerful opposition to it is certain. The root of much of this will be the money problem.



Given no worsening in the Cold War between now and January, the Administration will be even more eager than it was this year, as the presidential campaigns get underway, to call for a balanced budget.

This can mean only one thing: A defense budget frozen somewhere around the present $40 billion. Nearly $2 billion for *Zeus* will be hard to find, indeed.

Therefore, the Administration may be greatly tempted to marshal opposition against *Zeus* to try to kill it. Or, since it would be easier, postpone costly production and thereby put off having an operational AICBM until 1964—two years after Russia is expected to be in a position to, in the words of Defense Secretary Neil McElroy, "cream the country."

TESTING OF the Thiokol booster engine used in *Nike-Zeus*. The solid-propellant engine delivers 450,000 pounds of thrust in about four and a half seconds.

RLD'S LARGEST ultra-precision hardened bearing was ground by the Kayden ineering Corp. for production of giant radars needed for the *Nike-Zeus* system.

NASA Wants Small Business To Get Its Share

Civilian agency has good record in letting contracts to small firms and wants more on its buying list

by Paul Means

WASHINGTON—A new man at NASA intends to make it his business to see that small business gets its share.

But first he needs to know the names of small firms having the interest and ability to perform NASA contracts and subcontracts.

Jacob M. Roey, recently appointed Small Business Adviser, will start by screening a list of small businesses (those with under 500 employees) supplied by the Small Business Administration.

This is only the beginning. As Roey points out, "there are hundreds of small research organizations with competent staffs that have come into being almost overnight. It is our job to locate them and catalogue their interests and capabilities."

He asks any small business interested in having its name added to his list to contact him at NASA's Washington headquarters.

Roey views his job as one of education and information. He informs NASA procurement officers and large contractors of small businesses, singly or in teams, capable of performing certain contracts. He also informs small businesses of upcoming NASA contracts for which they might be capable of being contractor or subcontractor.

• **High batting average**—NASA's record of letting contracts to small businesses during their first six months of operation has been very good. The last quarterly report from NASA's Ames Laboratory shows over twice as many procurements going to small businesses as to large, and almost twice as many dollars.

Most of the Ames Laboratory procurements were for supplies and services, an area in which small businesses have greater capabilities. But the record indicates NASA's desire to give small business all the work they can handle.

NASA contractors also have a good record of subcontracting to small business. E. W. Brackett, NASA Procurement Director, points out that the **Rocketdyne Division** of **North American Aviation,** which has the NASA contract to produce the *Nova* million and a half pound thrust single chamber engine, placed 79.4% of its total subcontract work by volume with small business firms in 1958. Total dollars showed $40 million going to small business subcontractors and less than $28 million to large business subcontractors.

Roey's job, then, is to systemize the process, so that NASA and prime contractors know what small businesses are able to perform specific jobs, and so that the small businesses know what jobs are available.

• **General aims**—Though he is still drafting a policy statement outlining the goals of his job, Roey says the general programs he intends to institute are the following:

1. To compile a well-indexed file of small businesses.

2. To screen proposed NASA contracts to determine what portions could be performed by small businesses.

3. To invite small businesses to participate as members of the audience when details of NASA-proposed contracts are explained to potential bidders.

4. To give big business contractors names of interested small firms with subcontracting potentials.

5. To urge big business contractors to set up their own files of potential small business subcontractors.

6. to urge small businesses to pool their resources so that they can jointly bid on larger NASA contracts.

• **Some targets**—The evils in the contracting process detrimental to small businesses which Roey hopes to overcome include:

1. The natural tendency on the part of some procurement officers and technical staffs to award contracts to large firms of proven reliability.

2. The practice on the part of so large contractors to set up a stable subcontractors who then get most the subcontracts without competiti from the outside.

The area in which small firms ceive a lot of NASA contracts p sently is supply and services. But t area which Roey feels holds a gr future for small business is resear and development.

The Congress recently went on r ord as favoring the letting of contra to small business in this field. Unli the military program, NASA nee R&D work on many small systems a components which small busines could handle.

• **Made to order**—The very natu of the space program indicates th many opportunities exist for small bu nesses in this field.

One shot, custom-made spa probes lend themselves ideally to sm business development, since volur production line capabilities which fe small businesses possess are not neede Payloads on top of space probes a satellites vary from shot to shot NASA scientists attempt to increa their knowledge about the univers Much NASA payload contracting as the company to extend the state of t art in a specific field, and individu theoretical ability counts.

On the large space projects, such *Mercury, Vega, Centaur, Saturn,* a *Nova,* no one company is big enou to do the entire job. In these case small electronic, engineering, researc construction, and many other types firms become valuable junior partne on a competing team for the contra and after the contract is won.

Many small handmade items, tr mendously important in relation their size, can best be done in a sm intimate shop, where decisions can b made orally across the shop floor rath than routed through the chief engine up to the executive vice president.

Another reason small business should get their share of NASA co tracts is that the space administratio does not intend to adopt the systen concept of procurement, used to son extent in DOD. In the systems co cept, all contracts for a complete pr gram, including support equipmen training aids, spare parts, and oth items are placed with one contracto In such cases, small business can ser as subcontractors, but are shutout principal contractors.

Brackett states that NASA will u such a system only in crash progran where "time is of the essence;" th the usual procedure will be to "procu various items, or segments, separatel from different contractors, and int grate and assemble them ourselves

Pressing the Search for 'Whiskers'

Five to 10 years may bring usable materials with six times the strength of steel

by Jay Holmes

WASHINGTON—Metal "whiskers," a ndache for handlers of electronic ipment, may some day be a boon makers of missile structures, in ich high tensile strength is vital.

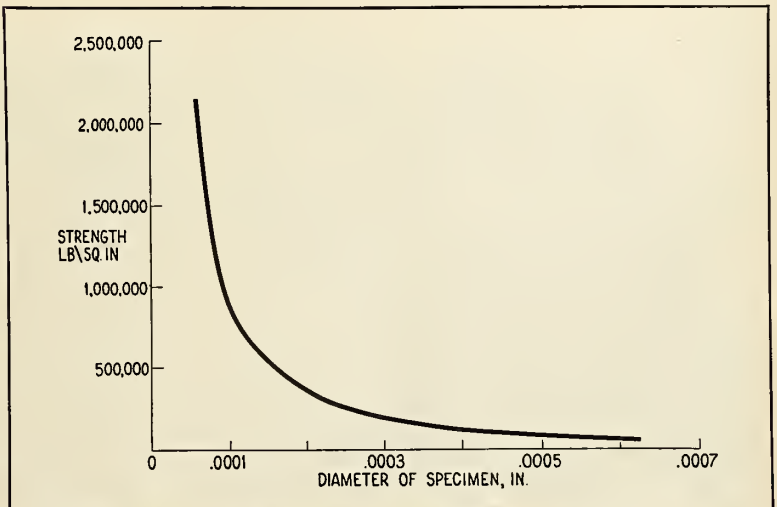
Some of these tiny metal fibers, ich grow out of bits of metal under vy electron bombardment, have a ength up to six times that of the ngest modern steel. The problem ore researchers is to form the whis-s into a material that can be fab-ated.

The strongest whiskers, which can e a tensile strength as high as 00,000 pounds per square inch, have meters of less than a 10,000th of an h. Their strength compares with a ximum of 350,000 psi for modern els.

Metal whiskers were discovered a rt time after World War II when gineers sought the cause of mys-ious short-circuits that developed in ctronic equipment after long use. en they took the black boxes apart, investigators found tiny wiry nds jutting from areas of metal faces under heavy electron flux. e strands are formed when atoms l out the metal and deposit them-ves in a regular crystal structure, metimes in the form of a spiral.

Why are whiskers so strong? A re pertinent question would be why n't most metals as strong as whis-s. For physicists have calculated—m the difference between electrosta-repulsion and bonding energy of tal atoms—that the tensile strength a perfect crystal theoretically should on the order of several million unds per square inch. The difference ween this figure and the much lower asured strengths of ordinary crystals thered physicists for many years. e discovery of whiskers' high strength nfirmed the theory. The weakness ordinary metal is due to imperfec-ns in the crystal structure.

The National Aeronautics and ace Administration is sponsoring tal-whisker research at California's **Propulsion Laboratory** and at the wis Research Center in Cleveland. rk is also under way at several in-strial laboratories, including those of **General Electric Co., Bell Telephone** and **Union Carbide Metals Corp.**

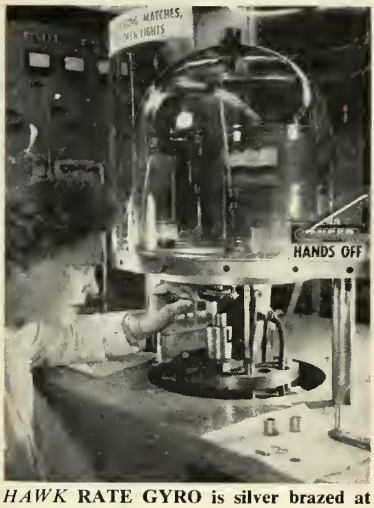


● **Five years at least**—Dr. Harold Hessing of NASA's Washington headquarters told M/R it might be possible to make usable materials from metal whiskers in 5 to 10 years. "I would say five years at a minimum," he said.

A great difficulty, Hessing explained, is that only one metal whisker in 10 has unusually great tensile strength. So far, he said, no one has devised a simple test of whiskers' strength other than to pull each one individually. "If we can pull it up to a certain load, then we know we've got one of the good whiskers," Hessing commented.

Joining the whiskers is another problem. Bonding material must be ductile and able to carry a shear load. Hessing said it may be possible to devise a method similar to one under NASA study in Cleveland for bonding wires together. The wires, immersed in molten copper, are forced through a funnel-shaped piece of metal. After the wires are forced together and the copper freezes a material of very high strength is formed. NASA scientists at Cleveland have made a package of ordinary steel piano wires ¼ inch in diameter with strength of 320,000 psi, compared with 150,000 psi for unpacked piano wire. There is no reason why such packaged wire cannot be made indefinitely long, Hessing said. The effect of the copper surface on the metal crystals is less than had been feared, he added.

● **Search for strength**—Tungsten is commonly used in experiments with whiskers because it is one of the strongest of the pure metals. Pure tungsten is stronger than pure iron. Steel, of course, is stronger than both but no one has offered any plan for growing iron whiskers with just the right amount of impurity to make high-grade steel. The accompanying graph shows maximum strengths of pure iron whiskers plotted against diameter. The curve for tungsten would have the same shape and would be a little above that for iron. A graph for tungsten wires bonded as in the NASA experiments at Cleveland would be a little below.



While some scientists are trying to grow longer and thicker whiskers, others are trying to eliminate or reduce them to eliminate short-circuits in electronic equipment. Several investigators report that alloys form fewer whiskers than pure metals. Nickel and tin are popular ingredients of such alloys.

MAXIMUM STRENGTHS of pure iron whiskers. Tungsten curve would be higher.

Hawk and *Lacrosse* Join Armory

Both highly mobile missiles will be deployed overseas in the next year to U.S. and NATO forces

HAWK **RATE GYRO is silver brazed at 1300°F in two minutes under controls.**

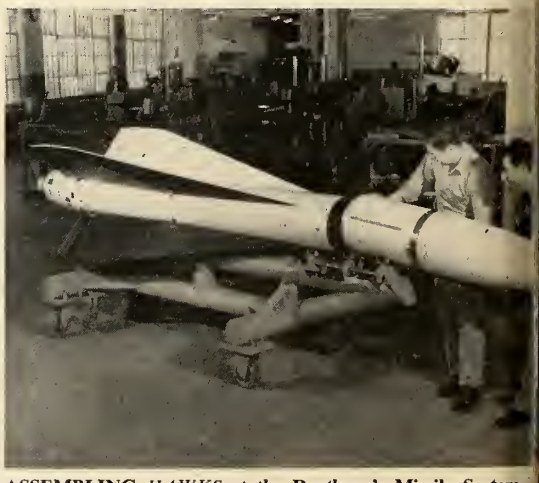
WASHINGTON—The Army this month added two powerful new missiles to its armory—the **Raytheon** *Hawk* and the **Martin** *Lacrosse*.

The first home of the *Hawk* is Ft. Bliss, Tex., where the 5th *Hawk* Missile Battalion of the 57th Artillery has been organized. The 300-man unit will train future *Hawk* missilemen for deployment in the United States and overseas.

Two *Lacrosse* units—the 5th Missile Battalion, 41st Artillery, and the 5th Missile Battalion, 42nd Artillery—have been organized at Ft. Sill, Tex. Each has about 170 officers and men.

The Mach 2.8 *Hawk* is designed specifically for intercepting enemy planes and air-breathing missiles flying from tree-top to medium altitudes in an attempt to dodge radar. It complements point defense provided by the **Western Electric** *Nike-Ajax* and *Ni* *Hercules*. Its range is about 22 mi

The *Hawk* has two stages—b powered by solid-propellent mot developed by **Aerojet** and **Thiokol.** T warhead is a high explosive. Raythe homing guidance in the missile dire it to its target.



The 1250-pound *Hawks* are hig mobile. They can be rapidly tra ported either by road or by helicop and aircraft. *Hawk* launchers ca three missiles which can be fired rapid succession.

The Mach 2 *Lacrosse*—a nucle tipped artillery missile—also is hig mobile. The entire system can mounted on a standard two-and-a-h ton Army truck. The system also c easily be airlifted.

The 19.5-foot missile has a rar

THREE *HAWKS* **ready to go are mounted on mobile launcher at White Sands Test Range. They can be fired in rapid succession.**

ASSEMBLING *HAWKS* **at the Raytheon's Missile System sion, Andover, Mass.** *Hawks* **may soon be manufactured in Eu**

LACROSSE, **the Army's new surface-to-surface tactical missile, is mounted and ready for launching from standard 2½-ton truck.**

about 20 miles. Its warhead can be ded with a variety of explosives and ped charges. It can pack a nuclear rhead or a variety of conventional losives or shaped charges.

Lacrosse is powered by a solid mo- developed by Thiokol. Its guidance terminal and provides a high degree accuracy, making it possible to hit all targets such as bunker entrances.

Millions of dollars worth of *Lasses* and *Hawks* are scheduled to deployed overseas during the next ar both in the hands of U.S. Army its and NATO troops. Marine units o will be equipped with *Hawks.*

Five NATO nations are moving ward production of *Hawks* in Europe their own forces through an agree- nt with Raytheon.

The *Hawk* and *Lacrosse* are among first of the new highly mobile fast-reacting tactical weapons being developed for the Atomic-age Army. Among those still under development: the **Martin** *Pershing, Davy Crockett,* **Aeroneutronics Systems** *Shillelagh* and **Convair** *Red Eye.*

The 500-to-700-mile *Pershing* will succeed the liquid **Chrysler** *Redstone.*

Red Eye is a tube-launched guided missile for use against low-flying aircraft by troops in the field. It is equipped with an infrared homing system.

Shillelagh is a lightweight surface-to-surface missile designed for use against armor, troops and field fortifications. It is expected to be operational by mid-1960.

Davy Crockett is a light nuclear-tipped rocket designed to be fired by one or two men in the field. It is being developed as a family of missiles.

BLAST OFF for a *Lacrosse.* **It can carry a warhead an estimated 20 miles.**

READY TO GO from its mobile launcher, *Lacrosse's* **terminal guidance enables it to strike enemy positions with pin-point accuracy.**

What's New in Fuzing and Arming

Remarkable achievements have been made in a field that is shrouded in secrecy and remains largely government-controlled in the hands of a small group

by Hal Gettings

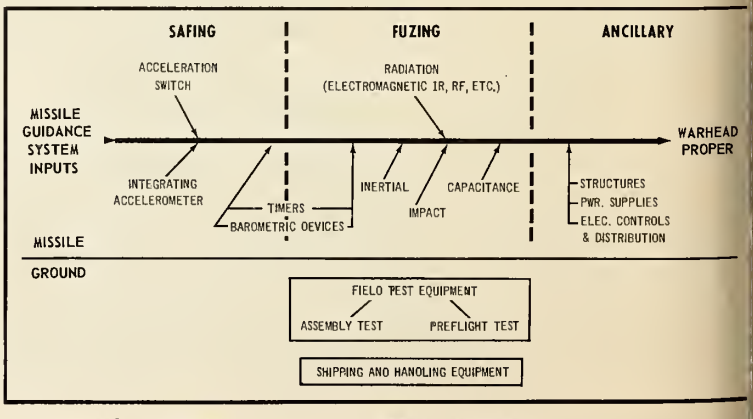
WASHINGTON—The primary function of a missile is to deliver a warhead to a target. Consequently, the warhead—with its arming and fuzing system—is a major subsystem of a missile. All the other subsystems operate only to enable the warhead to perform its function. The design and manufacture of an arming and fuzing system thus becomes a large and important part of a missile program, demanding the utmost in efficient design and reliability.

How do you make an explosive device so safe that it's practically impossible to detonate it accidentally—even if the missile carrying it blows up on the launch pad, or the jet bomber carrying it crashes on takeoff? How do you guard against a technician inadvertently putting a voltage on a fuzing circuit? And, after making it this safe, how do you get the thing to detonate without fail at exactly the time and place it's supposed to?

These are some of the problems that face the designers of arming and fuzing systems for both nuclear and conventional missile warheads. That they have solved these problems, at least to a remarkable degree, is evidenced by the fact that we have never had a premature nuclear warhead explosion—even when the weapon was involved in a bomber crash.

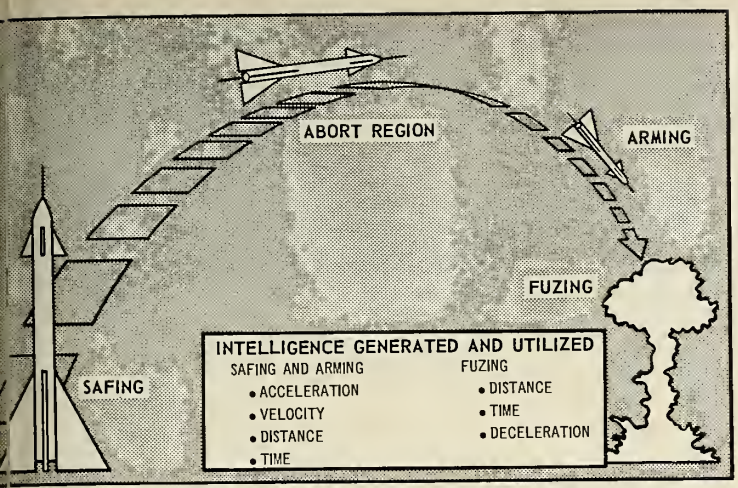
The safety factor is considered at least 1000 times more important than any other aspect of reliability. Designers actually shoot for a minimum of 100% reliability so far as safety is concerned.

Detonation reliability must then become a little less than 100% perfect. Design goal is aimed at what is sometimes called the "wooden bomb" concept. This means that the warhead must be capable of being dropped, stored for long periods under changing conditions, mishandled—in short, subjected to practically any sort of maltreatment—and then be ready to go on a minute's notice.



• **Shroud of secrecy**—A great deal of secrecy surrounds arming and fuzing systems—some no doubt justified, and some perhaps not. Of course, an argument for tight security is the fact that knowledge of the characteristics of a system can lead to second-order deduction of facts about the warhead itself. Knowing the sensitivity range of a proximity fuze, for instance, one can tell much about the size and capability of the nuclear payload. More important, knowing details of the system would allow an enemy to prematurely detonate the warhead.

Several manufacturers have stat privately that some of the governme agencies involved are chiefly interest in keeping fuzing systems in the ca gory of government-furnished equi ment—so that they may either pr duce the system or handle the subco tracting.



Whether this charge is true or n is a moot question. It is a fact, ho ever, that there is no central clearin house for industry information. It conceivable under such circumstanc that the state-of-the-art cannot a vance at a rate comparable to that related fields.

Accepting the need for tight s curity in this area, some sort of centr agency for coordination of past d velopments and of work in progre would help to provide answers f those with a need-to-know.

The arming and fuzing industry

INPUTS and components of a typical fusing and arming system.

UNCTIONS OF TYPICAL MISSILE SAFING, ARMING AND FUZING SYSTEM
ARMING is defined as handling and launching safety for own personnel facilities and story; the abort region is the area where the bird may be self-destructed without enation of warhead; arming prepares warhead for fuzing signal.

hole is in the hands of a small rp. In addition to the restrictions n limitations mentioned, there is r one customer—the military—for h business, and developments do not e to profitable commercial products.

• **Growth of participation**—Arming r fuzing of a nuclear warhead was le entirely by the Atomic Energy Commission until, in 1953, they agreed o transfer some of the responsibility o the armed forces. **General Electric** w the first industrial contractor to rak the barrier and produce a com-ple system from design through hard-w e production—for the *Lacrosse* nsile. GE is currently working on—o has completed—nuclear ordnance o jects for eight major missiles.

Bulova's Research and Develop-nt Labs have been in the business fo a long time and are currently w king on their 17th system. They re ntly were awarded a multimillion-do ar contract for the Army's *Persh-in* missile.

Besides GE and Bulova, there are pe haps three other companies with a m or interest in this field: **Minneapo-li Honeywell, Maxson,** and **Avco-Cros-le** Others involved to a lesser extent in ude **Bendix, Philco, Farnsworth, C lins, Emerson, Eastman, Melpar, W stinghouse,** and **General Mills.** T re are at least 30 major component su pliers.

Several government agencies are in the picture to a greater or lesser d ree. Army's Diamond Ordnance F e Lab worked in the field for many y rs. They were in at the beginning o the proximity fuze development in 1941, and have maintained their w k in this and related fields until they probably now have the most complete in-house capability of any agency. DOFL has also done considerable work in electronic miniaturization for fuze circuitry and other accessory areas.

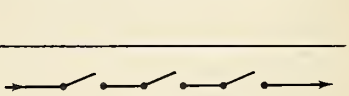
The Navy, too, was concerned with proximity fuze development in its early stages. Naval Ordnance Labs at Corona, Calif., and White Oak, Md., as well as Ordnance Test Station, Inyokern, are today involved with arming and fuzing development.

Other government agencies involved include AEC, Air Research and Development Command and Air Force Special Weapons Command.

Picatinny Arsenal has prime responsibility for all Army missile warheads. Their Special Weapons Ammunition Command acts as specifier, buyer, and technical consultant to system contractors. They may also procure components or subassemblies for the prime. Picatinny's Atomics Lab conducts periodic symposia on arming and fuzing for industry contractors.

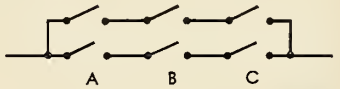
• **Tricky requirements**—Due to security restrictions, the problems and design criteria for A and F systems can be discussed only in principle. Several major problems confront the designer: extreme reliabilities, high accuracies, extreme environments, and tactical utility.

The double-barrelled reliability problem puts the designer on the horns of a ticklish dilemma: the safer he makes the fuze, the harder it becomes to make it operate at the proper time. This factor is overcome, to an extent, by use of redundancy in the firing circuits. An oversimplified example would be a circuit such as shown in the diagram. Switches A, B, and C would have to be closed to complete the circuit; the failure of any one would make the system inoperable. If parallel switches were added, then the likelihood of failure is reduced (assuming 100% reliability of the switches themselves). Redundancy has its limits, however, since space and weight are at a premium.



The high accuracies required in an arming and fuzing system are another problem source. The warhead must explode at a precise point in altitude or proximity to the target. It therefore must be sophisticated (almost intelligent), sensitive, and fast. Such complexity further adds to the reliability problem.

This complex and sensitive device must ride a missile through a wide range of extreme environments. It must maintain its integrity through the shock of initial blast-off, a gamut of temperature extremes, acceleration and deceleration, atmospheric re-entry (in some cases), and other shock and vibration.



Tactical utility requires a unit that can be stored for long periods, quickly assembled, easily tested and immediately available. It must be capable of all this in the hands of field-level personnel with training roughly equivalent to that given an ordinary field artillery crew.

The so-called "adaption kit" allows missiles to have a dual capability. Battlefield generals, fleet or air force commanders can choose between either conventional or nuclear warheads—and the missile can be so armed at a split-second command.

• **Complications**—The most simple fuzing system, of course, is the basic "hammer and nail" type—a pistol firing pin, for example. Starting with this concept, a system steadily grows more complicated. A "safety" is added to prevent premature firing . . . and further equipment is then needed to bypass or remove the safety at the proper time—for instance, a propeller must revolve

SIMPLE set of series switches are closed to allow fuzing signal to go to warhead.

PARALLELING second set of switches provides alternate path for B signal (redundancy).

a certain number of times or the projectile must rotate fast enough to throw out the safety. Then we can add acceleration inputs, barometric devices, radiation (or other electromagnetic) transducers, or any amount of complicated gear to make our system more sophisticated and safe—and potentially less reliable. It is one of the most complex devices in a missile.

The basic elements and optional control inputs of a typical arming and fuzing system are shown in the diagram. The choice of the various inputs, would, of course, depend on target characteristics, location, altitude, and any number of other factors. The more of these considered necessary, the more sophisticated the system.

A system's components include timers, accelerometers, integrators, gear trains, power packages, amplifiers, a maze of switches and electronics, logic panels, and unique sensing elements—all acting on programmed and sensed inputs to set in motion a chain of events leading to the final "moment of truth." All components must be of a precision and quality not required in other areas. Although designed to be used only once, they must be ready at all times to perform their assigned function with no question as to readiness and reliability.

Little is heard—or can be told—of the actual techniques and mechanisms developed to enable a missile warhead to do its job. Their importance must be judged not by the publicity they receive but by their extremely important part in successful missile systems.

Hoffman Acquires New Data Processing Machine

MENLO PARK, CALIF.—Capable of performing 480,000 decision-making operations per minute and storing up to 6 x 10^8 characters of information, a new data processing machine recently was purchased by Hoffman Laboratories Div. of **Hoffman Electronics Corp.**

First of its kind to be built, the $800,000 computer, called a Datatron 220, is a digital system with full magnetic-core memory.

To be employed in the performance of the U.S. Air Force electronic reconnaissance system, "Tall Tom," the giant computer was built by **Electro Data Division** of Burroughs Corp. Hoffman is directing the team of seven companies involved in the program for the USAF Aerial Reconnaissance Laboratory.

The system was dedicated formally here at **Stanford Research Institute,** during a recent meeting of the Tall Tom management policy board.

STANDARD SAMPLES FOR GASES-IN-METALS, U.S. Department of Commerce, National Bureau of Standards, Summary Technical Report.

Eight bars of ferrous materials whose oxygen and nitrogen content have been precisely determined comprise a new type of standard sample now available from the National Bureau of Standards.

In providing these reference materials for the calibration of commercial apparatus used to measure the gas content of metals, the Bureau has inaugurated a program of standard samples for gases-in-metals covering a variety of metallurgical products.

RESEARCH ON FIELD EMISSION CATHODES, E. E. Martin and H. W. Pitman, Linfield Research Institute for WADC, 69 pp., $1.75, available from OTS, U.S. Department of Commerce, Washington 25, D.C.

This program was undertaken in two phases, one of which led to improvement of stability of the field emission cathode and the other involving study of the electrochemical behavior of refractory metals used to make field emitters.

In the first part, methods were developed for greatly improving stability of the cathodes by avoiding changes in surface electric field and work function. Experimental testing of fixed voltage operation of a cold tungsten emitter was extended beyond 3000 hours. In other cases current drift rates less than 5% per 100 hours of operation over several hundred hours were observed at currents of the order of 10^{-4} amperes.

Improvement during repetitive, microsecond, pulsed operation at pulse currents up to 0.1 ampere was demonstrated. Techniques included careful vacuum practice, envelope material nearly impervious to atmospheric gases, and thoroughly degassed refractory metal shaped to minimize encroachment of secondary electrons on tube envelopes.

In the study of the electrochemical behavior of refractory metals, formation and dissolution of oxide layers appeared to have a major influence on surface smoothness and emitter geometry. Developed were an automatically controlled method of emitter shaping and a technique for removing material uniformly from small parts such as small cathode structures. The effect of variation of polishing cell parameters such as temperature, voltage and electrolyte concentration was also investigated.

Automatic Checkout Systems Compared

Curtiss-Wright's DEMON and Nortronics' NORSCAN are representatives of the fully transistorized development trends in the checkout field

by Charles D. LaFond

WASHINGTON—For those who have followed the rapid development of automatic checkout, the evolution to solid-state systems was logical and mandatory to achieve the desired very-high-speed and data-handling capabilities.

Last week's issue of M/R summarized the results of an industry survey of checkout systems. It was evident that solid-state systems are well past the dream stage.

To better understand just how much has been accomplished with these newer checkout systems, a close-up of two systems is presented: the **Curtiss-Wright** DEMON and the **Nortronics** NORSCAN—both fully transistorized, modularly constructed, completely self-checking, and extremely flexible in application. Although the two are similar in overall design, each has certain unique attributes. It is important to note that there are other similar systems, but DEMON and NORSCAN appear to be representative of the development trends in tomorrow's automatic checkout industry.

• **Design goal**—Both DEMON and NORSCAN were designed to achieve the principal goal: a broad system capability (1) not limited to any existing weapon system, (2) incorporating sufficient functional groups to accommodate many future weapons systems, and (3) adaptable to all levels of testing. In other words, the system design is to be such that the inherent capability might permit module deletion, but not require addition, when adapted to a particular weapon system checkout.

• **Limitations**—The one limitation foreseen by both manufacturers in their respective systems is the ability of the system applications engineer responsible for determining the programming for each checkout program.

Curtiss-Wright DEMON

DEMON was formally introduced at the Benesia Arsenal in Benesia, Calif., in March of this year. It also has been in continuous use at the Santa Barbara Division of Curtiss-Wright Corporation since December, 1958.

In a current demonstration setup, DEMON is shown (Fig. 1) checking a *Nike-Ajax* missile system; however, this application utilizes something less than 5% of its total in-being system capability. There are no existing weapons systems today that would require or use the total capability of DEMON, according to Curtiss-Wright.

Company engineers believe that had DEMON been available when the *Nike-Ajax* was introduced operationally, considerable savings in time and dollars would have resulted. For example, utilization of that portion of DEMON which is now being used to check the *Nike* missile would cut by more than half the number of personnel required for tests. The skill level of those persons remaining would be several grades lower than previously required. One skilled operator still would be required for each repair crew, mainly to assure the physical quality of the repair.

Another important consideration, they believe, would be a considerable decrease in time and experience required at the Ordnance Guided Missile School, Huntsville, Ala., where Army missile maintenance crews are trained. As an example of the slash in test time required, DEMON now takes less than one minute to locate a faulty component in the missile power supply—as contrasted with several hours on a manual basis. Further, upon location of the fault, detailed visual repair information could be made immediately available to the operator.

• **Major subsystems**—Referring to Fig. 1, the DEMON system consists of a Flexowriter and the three adjacent equipment racks. The fourth rack contains various stimulus generators used in checking the *Nike,* including an analog-tape stimulas generator. The missile shown was supplied as Government-furnished equipment (GFE) by the Department of Army (certain pieces of test equipment have been removed from the missile depicted for security reasons).

The following is a brief description of each of the major DEMON subsystems as shown in Fig. 2:

• Input-output—Handled by a Model FPC Friden Flexowriter, modified slightly to meet system requirements. Standard 8-channel tape is used. Information can be fed into the system by either punched tape or direct "typing" of coded signals into the file memory. System output is also handled by the Flexowriter. Output signals result in punched tape. This is fed into the receiving mechanism and automatically typed, thus permanently recording the data.

• File memory—Consists of magnetic tape and handling mechanism (paper tape can and has been used), which provides storage of programmed information necessary to perform the following: (1) switching to apply

Editor's Note: The reference to the use of a "trend index" by Curtiss-Wright in Part I of this series last week was in error. The Nortronics "confidence index" is the only such trend-type comparison standard that M/R has found employed in any checkout system.

stimuli to injection points; (2) delivery of appropriate max. and min. values for each test for comparison with measured values; (3) execution of address functions based on go-no go response; (4) delivery of any of the test-block stored contents into the system.

• Buffer memory—Provides time-scale changing from the 12,500-character/sec. rate of the file memory to the random rate with which the stored information normally is utilized without significantly delaying acquisition of the information contents when needed.

• Decoder matrix—Accepts stored instructions from the buffer memory, and translates the instructions into an executed pulse delivered at the address specified by each instruction.

• Encoders—Convert all quantities (voltage, frequency, elapsed time) to be measured into binary-coded decimal form. Measurements are performed by comparing numerical data representing the function to be measured with numerical limits programmed by the control system.

• Search control—Supervises the movement of the magnetic-tape file memory, in response to signals arising elsewhere, to prepare for or actually to transfer one test block between file memory and buffer memory.

• Comparator—Evaluates encoded test results with respect to programmed tolerance units. Using simple logic circuitry (subtraction method) the comparison is accomplished in bi coded decimal form. A voltage-s detector is used as an "ON-OFF" c parator and to detect simple switcl functions.

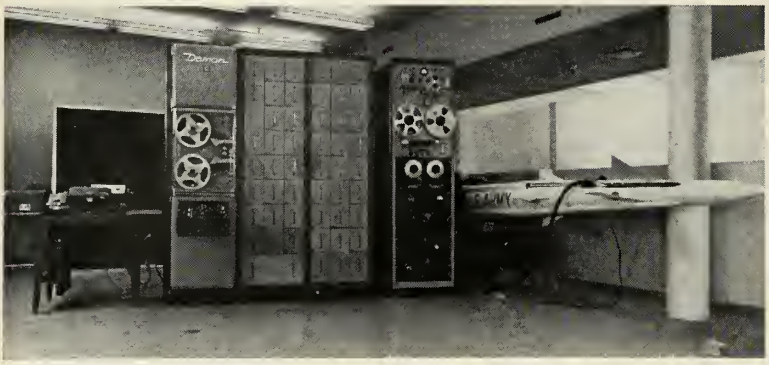
• Clock—Used in the testing (in effect, the controlling) of l complex systems. A synchronous c trol logic was chosen in the interes safety and economy in preference a nonsynchronous technique. clock controls transfer of informa between all internal subsystems for all input-output operations.

• **Features**—A summary of principal features will best illustr the capabilities of DEMON.

Storage capacity is greater than 1 x 10^6 bits. The system also include "table lookup" for simultaneous eva ation of dependent variables (from functional subsystems) over a gi range. Buffer capacity is 1792 bits.

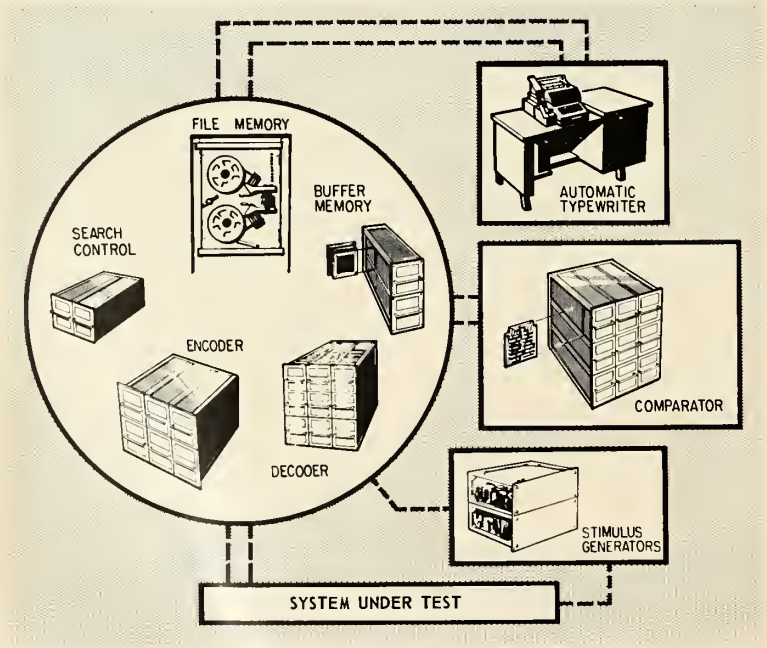
Programming is digitally control by magnetic tape (patch boards not employed). To minimize physi test equipment, the system utili magnetic tape for an analog in stimulus to the system under test.

Servo-stimulus control is provic for all high-frequency test signals t cannot be programmed on the ana tape. The output of the signal genera is precisely controlled through the of error feedback circuits which co pare the signal generator output agai the desired output, independent knob position. Thus signals are ref enced to the standard against whi the system responses are measured.



A time sharing system is so signed that it can time share the ce tral control subsystem for a number maintenance work stations simultar ously.

Readout for the test results is pr vided in terms of distance from g distance from no-go, or distance fro any arbitrary given point.



The present DEMON Flexiwrit will print out any information desire from complete test data to select failure data. This is recorded punched tape, and if desired can transmitted via teleprinter to stimula a logical supply system and thus i sure that a proper balance of stor is maintained.

A new visual readout system, en ploying a view screen, is being deve oped by Curtiss-Wright. The system w be driven by the DEMON control sy tem and will display actual photograp of the malfunctioning area of the sy tem under test, the procedure to followed in repair (or replacement and the next step to be taken by t operator after repair.

No operational failures have be experienced in the DEMON, accordir

CURTISS-WRIGHT'S DEMON checks out a *Nike-Ajax*. DEMON—along with Nortronics' NORSCAN—represent solid state technology for automatic checkout. (Fig. 1)

SUBSYSTEMS of DEMON. Fully transistorized, system is modularly constructed, completely self-checking, and extremely flexible in application. (Fig. 2)

ca company spokesman. All circuits e been designed for maximum in- endence of component tolerance, ch permits the use of 10% com- ents (resistors, capacitors, etc.) ughout the system.

Nortronics NORSCAN

Nortronics, a division of the Nor- p Corporation in Hawthorne, Calif., recently completed its first proto- e of NORSCAN, acronym for Nor- ics System Computing Analyzer e Fig. 3). But, according to a com- y spokesman, the system is founded thoroughly developed and proven cepts.

Principal memory device in NORS- N is its magnetic drum, having a acity of over ½ million informa- bits.

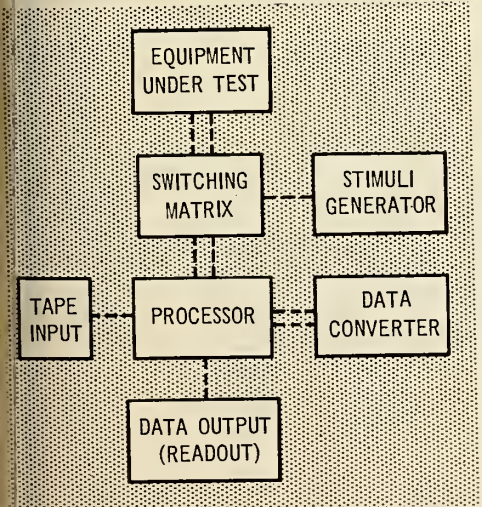
A major innovation in the Nor- ics system is the employment of confidence index" (discussed in de- in M/R, June 29). The index is ded from 99 to 0 and provides a ans against which test readings can compared. This furnishes an ac- ate indication of how good a go ding really is. Either analog or dig- signals may be measured against s standard.

When a time base is added, a rate change is generated. From this rate, predicted time-to-failure (due to nponent drift) is established. This e can be compared with a fixed time rval to determine a "drift index." dicted times-to-failure greater than equal to the fixed time interval re- in a maximum rating of 99; those than the fixed time figure are ex- ssed as ratios with values from 0 99. (The fixed time interval is based the predicted mean time to failure.)

• **Principal units and features**—(Refer to the simplified block diagram in Fig. 4.)

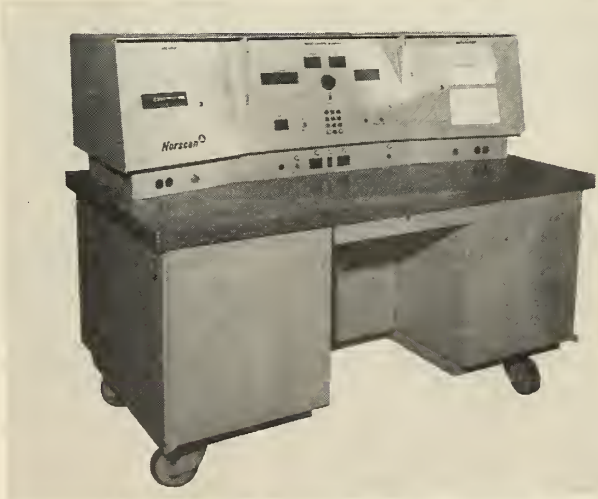
• Stimuli generator—All forcing functions are generated within the stimuli generator. These may be electronic, pneumatic, optical, mechanical, or thermal. Provisions are made for flexibility in time, amplitude, and phase. Control of function amplitudes and sequence is accomplished by the processor that specifies which signals should be fed to the switching matrix and then into the system.

• Switching matrix—Solid-state devices are used in the switching matrix for switching electronic signals. The matrix is capable of making 10,000 measurements/sec. This can be programmed to read 100 signals on 100 wires in 1 sec., or 10 signals on 1000 wires in 1 sec., or any combination thereof. It also contains basic switching blocks for switching mechanical or pneumatic signals and presents an electrical impedance of one megohm (or greater) to the system under test.



The processor controls the operation by determining which signals shall be switched to the proper wire at the proper time. Outputs from the system under test are sent through the switching matrix. If the outputs are digital signals, they go directly to the processor. If the outputs are analog signals, they are fed to the data converter.

• Data converter—The data converter performs an analog-to-digital conversion with an accuracy of 0.01% and a conversion speed of 25 microsec. The converter contains signal transducers for converting pneumatic or mechanical signals to electrical digital signals. It also has impedance matching devices and contains elements for making necessary scaling changes.



• Processor—The processor is an internally programmed digital computer, with a magnetic drum as its principal memory unit. The processor also contains an arithmetic unit, display controllers, displays, program unit, output controller, core buffer, and magnetic tape unit. The magnetic drum memory has a storage capacity of 500,000 bits of information. The core buffer, having a capacity of 1000 bits, is used for instruction storage to allow for minimum program execution time. It is also used as a buffer between the processor and the printer, between the main drum memory and the magnetic tape unit, and between the arithmetic unit and the selection matrices, which send data to, and collect data from, the system under test.

• Tape input—A high-speed tape reader, with a capability of 400 characters per second, provides the input to the processor. Initially, the tape is used to store information on the magnetic drum with respect to test sequence and test limits. Once the information has been stored on the magnetic drum, the operator energizes the test equipment and the test procedure is programmed automatically. Should any changes be made in the system under test, a new tape is inserted, the previous information erased, and new information reflecting the system changes is placed on the magnetic drum.

• Data output—The data output is under complete control of the processor. A number of different outputs from each unit may be used. The types of output depend upon the operating usage of the test equipment. They may be visual, oral, punched tape, punched

SIMPLIFIED block diagram of Nortronics' NORSCAN f broad capabilities. (Fig. 3)

PROTOTYPE CONSOLE of NORSCAN. Magnetic drum memory device in system has one-half million information bits capability. (Fig. 4)

card, printed copy, or any combination of these. Information from the magnetic tape memory may be printed in clear text for purposes of reliability reports, record keeping, and logistic determination. Reprovisioning data is also available as an output by programming the processor to provide punched cards or punched tape whenever a malfunction occurs in the system under test. This information can then be further processed or used directly to order replacement parts.

• Magnetic tape file—To store information permanently for future reference, such as malfunction prediction through the confidence index system, all data is recorded in a magnetic tape file. The unit might be comprised of an Ampex Model 800 recorder and a series of read-write amplifiers. If, for example, 30 amplifiers were employed, 15 channels would be available. A ½-inch-wide magnetic tape can store 200 bits/inch/channel. A 2500-foot tape could accommodate 7.5 x 10^6 bits with ease. Since the magnetic tape unit also records the results of the analyzer's self-test, a complete record is obtained on the unit and is available for analysis.

Fibreglass Tower Used with UCLA Antennas

LOS ANGELES—A fibreglass tower with interchangeable antennas has gone into operation at UCLA. The 18-foot structure, utilizing fibreglass to prevent metallic distortion of radiation patterns, rests on a pillbox base and both tower and antenna can be rotated independently on vertical and horizontal axes.

The tower was built by **Blaine Electronetics** and can be operated either by controls inside the base or by laboratory controls two floors below. A transmitting antenna 60 feet away illuminates the tower antenna.

The antenna is being used for various projects in advanced teaching of electrical engineering, radar, communications and other fields. One program under way involves research into transmission of electromagnetic signals between a missile re-entering the atmosphere and the ground. This transmission is difficult because of the ionized layer surrounding a re-entry vehicle.

Leach Opens Laboratory for Solid State Research

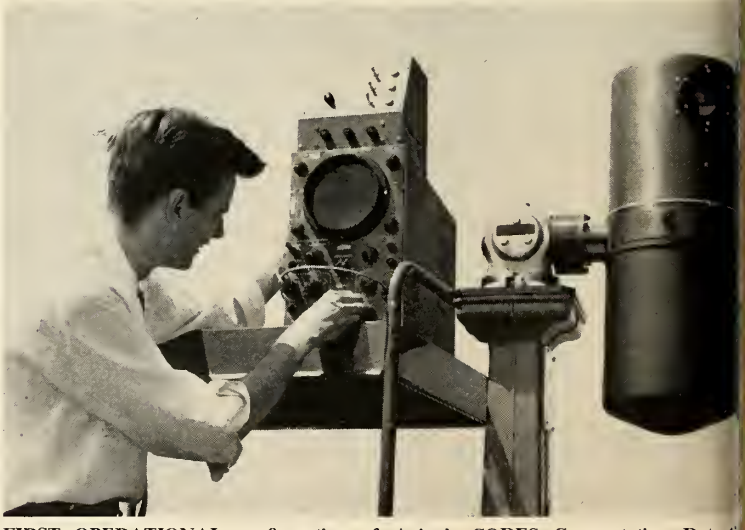
LOS ANGELES—A new laboratory designed for flexible research into solid-state devices has been opened by the **Leach Corporation.** Located at the firm's relay division, the lab will "develop solid-state packaging with no preconceived ideas," and will endeavor to meet the rapidly changing logic of space control and communications.

According to company officials, the lab will augment other work being done at previously-established electromechanical and chemical labs, as well as the new Leach Production Reliabilty Center. The lab has been well equipped with general and specific solid-state development instrumentation to permit fast study and checkout.

The lab has already developed a new programming timer which combines subminiature crystal can relays with solid-state devices in a common circuit for use in sequence progr ming.

The solid-state package deve ment philosophy at Leach is base the belief that "even in the most r lutionary electronic fields, no new vice has ever succeeded in comple supplanting the old." Therefore, L engineers are looking to the con of combining components based on peculiar characteristics of each This design logic, they predict, wil the outgrowth of research in s state packaging.

Recruiting Heavy at Military Electronics Me



WASHINGTON—A "highly successful" third annual National Convention on Military Electronics here last week pointed up the importance of missiles in the military electronics industry. Almost all the technical sessions were devoted, at least in part, to missiles applications of electronics systems and components.

The convention, sponsored by the IRE Professional Group on Military Electronics, was attended by nearly 400 engineers—almost twice last year's figure. Some 80 exhibitors showed their latest developments in the field. Although nothing outstandingly new was to be seen at the exhibits, several items such as a pocket-sized computer and the free world's largest radar set attracted considerable attention.

The exhibit that drew the largest crowds was **Martin's** moon-satellite ball machine. Walter Mitty-type as designers could crank guidance thrust data into the machine launch a steel-ball satellite which co orbit or land on the moon if t calculations were correct.

Engineer recruiting was especi heavy. At least 25 major compa had representatives at the meeting the competition for qualified peo was the fiercest since before the stret out. One recruiter estimated that th were about 10 jobs available for ev eight men interested—a demand ab double that of last year.

Two **General Electric** engineer R. S. Grisetti and E. B. Mullen— ceived the annual M. Barry Carl Award for their paper on base guidance systems.

FIRST OPERATIONAL configuration of Avion's CODES Commutating Detecti System was exhibited at the 1959 Military Electronics Show in Washington. The mu channel, highly sensitive, infrared receiver (first described by M/R, April 20, 19 employs single-channel electronics by commutating the stored outputs of 30 detec cells and uses a single amplifier. It was developed for Air Force Cambridge Resea Center to study satellite-detection feasibility using IR techniques.

Missiles and Rockets Editorial Index

Readers are invited to save the o wing six-month index covering M R issues of Jan. 5, 1959 through u 29, 1959. This index is a reference u e to major news and technical r les published in M/R during the ir half of the year.

ASTRIONICS

Atennas

AVCO PROJECT; Radar reflector said to h ly cut weight, cost, by M/R Staff, 3/23/59, p. .

Checkout

PUSH FOR AUTOMATIC CHECKOUT; Fully r storized systems are rapidly being developed e is operational, by Charles D. LaFond, M/R ciate Editor, 6/29/59, p. 39.

Communications

CESSFUL AME IS UNVEILED; Page Communi- ns' gear tested in North Atlantic is expected nd more use on ionoscatter circuits and offers ntial for increased channel capacity, by les D. LaFond, M/R Associate Editor, 6/22/59, .3.

MMUNICATIONS SATELLITES: A LARGELY LECTED FORCE FOR PEACE; Long-proposed e relay system, now technically and economi- feasible, still gets little non-military atten- by Hal Gettings, M/R Associate Editor, /59, p. 38.

THE EDGE OF INTERSTELLAR SPACE; In 1962 A will fire minimal payload rocket and in next years will perfect communications for re- ng its data, by Hal Gettings, M/R Associate or, 4/13/59, p. 19.

NOISE TEMPERATURES IN PARAMETRIC LIFIER; by M/R Staff, 3/9/59, p. 44.

KHEED DELIVERS 9-LB. RUGGED TV SYS- TO ABMA; by M/R Staff, 2/16/59, p. 24.

Components

F REPORTS ISSUED ON CAPACITORS, TRAN- ORS; by M/R Staff, 2/9/59, p. 79.

USES 'WOOFERS' TO TEST COMPONENTS; M/R Staff, 1/12/59, p. 31.

Computers

R TO RESEARCH PHOTOCHROMIC MEMORY; M/R Staff, 5/29/59, p. 32.

HLGREN DEVELOPS COMPUTER; Used for ris, machine will handle half-million bits of rmation each second, by M/R Staff, 4/27/59, 29.

Data Processing

ICO DESCRIBED AS A NEAR-UNIVERSAL T FACILITY; Programmed tester developed by tronics automatically checks out complex mili- hardware; company says it will sharply cut s, by Charles D. LaFond, M/R Associate or, 3/30/59, p. 29.

W, COMPACT UNIT CONVERTS DATA IN- GHT; by M/R Staff, 2/2/59, p. 31.

General

SCOW BRIEFS; by Dr. Albert Parry, Con- uting Editor M/R, 6/22/59, p. 40.

ST COAST INDUSTRY; by Fred Hunter, M/R ociate Editor, 6/1/59, p. 48.

CTRONIC OUTPUT TO DOUBLE BY 1965; at's the future for electronics in MSE? by liam E. Howard, M/R Associate Editor, 5/25/59, 25.

GE'S NEW SLAVE MECHANIC HAS 'FINGERS'; 'Handyman'—result of four-year development—will go to work in radioactive areas, by M/R Staff, 4/20/59, p. 40.

HIGHLIGHTS OF IRE CONVENTION; Transistor output to pass $350 million by 1963; sales to near $300 million, by Charles LaFond, M/R Associate Editor, 3/30/59, p. 14.

INTEGRATED ELECTRONICS FOR SMALL MISSILES; Prime consideration in design and manufacture is that the missile be considered as a round of ammunition, by Gordon E. Sylvester, 3/2/59, p. 21.

CONTINUED GROWTH IN MILITARY ELECTRONICS; Armed Services seeking those companies with electronics capabilities to serve as missile, astronautics prime contractors, by Raymond M. Nolan, M/R Associate Editor, 2/9/59, p. 26.

FUTURE OF ELECTRONICS: GROWTH WITH ASTRONAUTICS; EIA President David R. Hull gives a probing look at missile electronics today and predicts tomorrow's uses, 2/9/59, p. 28.

THE AGE OF THE ELECTRON; Guest Editorial, by Dr. Ernst Weber, 2/9/59, p. 7.

ELECTRONICS BUYING SHOWS QUARTERLY INCREASE; by M/R staff, 2/2/59, p. 31.

AMPHENOL AND BORG FIRMS MERGE ELECTRONICS OUTPUT; by M/R Staff, 1/19/59, p. 27.

1958 ELECTRONIC SALES HIT RECORD $7.7 BILLION; by M/R Staff, 1/12/59, p. 27.

TWO NEW REPORTS ISSUED ON ELECTRONICS; by M/R Staff, 1/5/59, p. 29.

Infrared

UNIT COOLS IR GEAR TO AS LOW AS 60° K; by M/R Staff, 5/25/59, p. 32.

AVION DEVELOPS NEW IR SEARCH SYSTEM; CODES, built around commutating infrared detector, will be modified for satellite tracking, by Charles D. LaFond, M/R Associate Editor, 4/20/59, p. 32.

TWO APPROACHES FOR COOLING IR DETECTORS; by M/R Staff, 2/16/59, p. 23.

SERVO CORP. MANUFACTURES 12-INCH IR DOME; by M/R Staff, 2/16/59, p. 24.

Guidance

MIDCOURSE GUIDANCE IS NECESSITY FOR INTERPLANETARY TRAVEL; Venus flight would require orbit about the sun and eventual capture by planet, by L. T. Seaman, 2/9/59, p. 40.

SPACE NAVIGATION POSES NEW REQUIREMENTS; Automatic, self-contained inertial systems will be required to provide precise velocity vector control, by Frederick Stevens, 2/9/59, p. 37.

INTERPLANETARY GUIDANCE FOR MAN IN SPACE; Existing components will be accurate enough for unmanned probes with possible radio control for cutoff and staging. But next generation of manned vehicles will impose a different set of requirements headed by reliability, by Lawrence S. Brown, 2/9/59, p. 67.

THE HOW AND THE WHY OF INERTIAL GUIDANCE; While basic principles have been known for many years, solution of some of the problems peculiar to ballistic missiles is only now becoming a reality, by F. K. Mueller, 2/9/59, p. 49.

SIMPLIFIED GUIDANCE PROPOSED; by M/R Staff, 1/12/59, p. 27.

LEAR DESIGNS GUIDANCE FOR MANNED SATELLITE; Broad features appear feasible in system for integrating accelerometers and retrofitting 'Bootstrap' gyros, by M/R Staff, 1/5/59, p. 26.

Gyros

FREE ROTOR GYROSCOPE DEVELOPED BY AUTONETICS; by M/R Staff, 5/11/59, p. 21.

ROLL REFERENCE GYRO STARTED BY SPIRAL SPRING; by M/R Staff, 3/9/59, p. 44.

NEW APPROACH FOR LIQUID FLOATED GYROS; Norden Division of United Aircraft gets patent for unheated gyro that mechanically compensates for temperature variations, by M/R Staff, 2/16/59, p. 18.

GYRO DRIFT DEMANDING NEW MEASUREMENT TECHNIQUES; by Ralph Hookway, 1/19/59, p. 22.

SPERRY DEVELOPS NEW FLOTATION FLUID; by M/R Staff, 1/12/59, p. 27.

Measurement

NEEDED: NEW VELOCITY MEASUREMENT UNIT FOR SPACE; Is the Optik—based on speed of light—the answer for the confusion in scientific terms? by Maj. William C. Mannix, USAF, 4/27/59, p. 21.

LET'S CONSIDER THE OPTIK; editorial, by Clarke Newlon, M/R Executive Editor, 4/27/59, p. 7.

GYRO DRIFT DEMANDING NEW MEASUREMENT TECHNIQUES; by M/R Staff, 1/19/59, p. 22.

Miniaturization

GE OFFERS NEW MICROMODULAR CONCEPT; Company claims eraser-size device named TIMM utilizes heat losses and lends itself to stacking for varied uses, by M/R Staff, 5/25/59, p. 28.

MINIATURIZATION—A SWELLING TIDE; Chain reaction of new breakthroughs could lead to microscopically small parts before trend runs its course, by Heyward E. Canney, Jr., M/R Contributing Editor, 6/8/59, p. 39.

Optics

GIANT MIRROR CREATED FOR NSF'S NEW OBSERVATORY; Corning's reflector largest built in 25 years, was made by 'sagging' and must cool for seven months, by Donald E. Perry, M/R Managing Editor, 2/23/59, p. 23.

THEODOLITES DETERMINE AZIMUTH FOR JUPITER; Optical-electronic combination provides method for automatic alignment and monitoring of inertial guidance systems, by M/R Staff, 2/2/59, p. 29.

Plasma

PLASMA ENGINE DELIVERS NEARLY 2-LBS.; Republic's experimental 'magnetic pinch' engine produces over 4000-lbs. at peak with 1700 sec. Ist, by M/R Staff, 6/8/59, p. 34.

ARGMA'S PLASMA JET TEST FACILITY IN OPERATION; Prototype model for aerodynamic heating tests reaches 50,000° fusing argon gas with 13,000 fps flow rate, by M/R Staff, 3/23/59, p. 39.

Power Sources

MINIATURE BATTERIES HAVE HEAVY MISSILE USE; Yardney's latest Silvercel may make possible more pre-flight tests for reliability. Early model saw service in Viking; many employed in today's birds, by Donald E. Perry, M/R Managing Editor, 2/23/59, p. 28.

Production

NEW BLOCK GROUP STRESSES MODULAR CONCEPT; by M/R Staff, 3/9/59, p. 43.

INTEGRATED ELECTRONICS FOR SMALL MISSILES; by M/R Staff, 3/2/59, p. 21.

Radar

RADAR DEFENDED AT AFCEA; by M/R Staff, 6/1/59, p. 40.

Telemetry

RECORDER SIZE AND WEIGHT CUT; Ampex AR-200 weighs one-third as much and is half the size of previous magnetic tape recorders, by Charles D. LaFond, M/R Associate Editor, 6/15/59, p. 35.

NEW BLOCK GROUP STRESSES MODULAR CONCEPT; K-Block modules produced by ASCOP can be used in various telemetering systems as well as data multicoding, by Donald E. Perry, M/R Managing Editor, 3/9/59, p. 43.

NEW COMPACT UNIT CONVERTS DATA IN FLIGHT; by M/R Staff, 2/2/59, p. 31.

EGLIN TELEMETERING CONTRACT IS FOR $500,000; by M/R Staff, 1/19/59, p. 25.

Thermo-Electricity

PROSPECTS FOR THERMO-ELECTRICITY; Heavy investment in research gives hope for long-lived power units for space application, by Hal Gettings, M/R Associate Editor, 6/22/59, p. 29.

Tracking

RADAR IS STRONGLY DEFENDED AT AFCEA CONVENTION; by Hal Gettings, M/R Associate Editor, 6/15/59, p. 40.

NASA'S PROJECT MERCURY RANGE TO COST $12 MILLION PLUS; Worldide tracking system with unprecedented reliability must be operating within year, by Paul Means and Hal Gettings, M/R Associate Editors, 4/18/59, p. 26.

AVION DEVELOPS NEW IR SEARCH SYSTEM; by M/R Staff, 4/20/59, p. 32.

SIMPLIFIED TRACKING GEAR PROVIDES MUCH DATA; Independent Sohio station uses interferometer principle to track satellites—even Lunik—and records on two-channel direct-writing oscillograph, by Donald E. Pierce, 3/16/59, p. 29.

RADIO SEXTANT CAN TRACK SUN, MOON CONTINOUSLY; by M/R Staff, 3/9/59, p. 44.

NASA PLANS INCLUDE EAST-WEST MINITRACK FENCE; Other goals are two additional parabolic dishes for continuous deep-space tracking, and developing safe tracking and communications for man in space, by Paul Means, M/R Associate Editor, 3/2/59, p. 13.

U.S. AGENCIES SILENT ON LUNIK TRACKING; by Frank McGuire, M/R Associate Editor, 2/2/59, p. 21.

THEODOLITES DETERMINE AZIMUTH FOR JUPITER; by M/R Staff, 2/2/59, p. 29.

TEMCO DEVELOPS TV SURVEILLANCE SYSTEM; by M/R Staff, 1/12/59, p. 31.

Transistors-Tubes Semiconductors

MINIATURIZATION—A SWELLING TIDE; by M/R Staff, 6/8/59, p. 39.

SIMPLE SOLION MAY FILL LOW FREQUENCY GAP; by Charles D. LaFond, M/R Associate Editor, 6/1/59, p. 39.

TUBES AND TRANSISTORS: WHERE DO WE STAND? M/R survey shows that if anyone wins 'battle' it'll be to benefit of entire industry, by Hal Gettings, M/R Associate Editor, 6/1/59, p. 41.

RCA DEMONSTRATES SOLAR CELL USING GALLIUM ARSENIDE; Company also shows new 'tunnel' diode and rectifier, calls development of vital importance, by M/R Staff, 5/11/59, p. 16.

NEW WAY TO 'GROW' GERMANIUM; by M/R Staff, 5/4/59, p. 26.

HOW NBS RESEARCHES SEMICONDUCTORS; Studies include crystal growth, electrical and optical measurements, carrier lifetime, nuclear magnetic resonance, and theory, by Charles D. LaFond, M/R Associate Editor, 4/27/59, p. 31.

RCA DEMONSTRATES THIMBLE-SIZE TUBES; by M/R Staff, 4/6/59, p. 48.

TRANSISTORS VS. TUBES; . . . are arbitrary military design specifications jeopardizing U.S. security? by Donald E. Perry, M/R Managing Editor, 3/16/59, p. 21.

PHOTO-DUO-DIODE SHUTS OFF CURRENT IN DARKNESS; by M/R Staff, 3/9/59, p. 44.

TUBE SAID TO RUN YEARS ON WEAK SOLAR POWER; by M/R Staff, 2/2/59, p. 31.

ASTROPHYSICS

Astronomy

SPACE OBSERVATORY IN THREE YEARS? NASA is spending $3.5 million to solve the remaining problems and bring a revolution in astronomy; 1.5 million pound thrust engine clusters are believed adequate, by Hal Gettings, M/R Associate Editor, 6/29/59, p. 42.

OHIO STATE TEAM MAKES LOW-COST RADIO TELESCOPE; Staff Report, 5/4/59, p. 27.

WHAT IS TOPOGRAPHY OF MOON'S OTHER SIDE? That terrain may be rougher with more craters and smaller mares, astronomer believes, by Dr. I. M. Levitt, Contributing Editor, M/R 2/16/59, p. 14.

DETECTION SEEN POSSIBLE BY STAR OCCLUSION; ACF technician proposes to AAS meeting that telescope be mounted to a space platform and stabilized by slaving it to three reference stars, M/R Staff Report, 1/12/59, p. 23.

BIG PINE TELESCOPE TO GO IN OPERATION SOON; M/R Staff Report, 1/5/59, p. 14.

General

HEAT AND METORITE IMPACT EFFECTS STUDIED; M/R Staff Report, 6/15/59, p. 22.

IONOSPHERE REPORTED BIGGER THAN SUPPOSED; M/R Staff Report, 5/11/59, p. 41.

Nucleonics

TOP SCIENTISTS FIND ARGUS OPENING NEW AVENUE TO EXPERIMENTATION; First detailed discussion of historic tests confirms theories of Christofilos, who calls for further projects, by Charles D. LaFond, M/R Associate Editor, 5/18/59, p. 37.

NUCLEAR EXPLOSIONS IN SPACE (first in a series of four articles); A scientific explanation of PROJECT ARGUS and how an electron accelerator could lead to creation of an artificial particle belt, by Prof. S. Fred Singer, M/R Contributing Editor, 3/30/59, p. 33.

NUCLEAR EXPLOSIONS IN SPACE (second of a series of four articles); Trapped radiation will be problem for manned vehicles. Close burst to ICBM could make its bomb inoperative. Defender may have to revise anti-ICBM strategies, by Prof. S. Fred Singer, M/R Contributing Editor; 4/6/59, p. 36.

NUCLEAR EXPLOSIONS IN SPACE (third of a series of four articles); High-altitude blasts seriously interfere with radio and radar. Complete knock-out of electronic defense is unlikely. Artificial release of molecules could sweep up extra ionization, by Prof. S. Fred Singer, M/R Contributing Editor, 4/13/59, p. 21.

NUCLEAR EXPLOSIONS IN SPACE (last of series of four articles); Many techniques exist for detecting trapped particles. But high-altitude bursts at some latitudes might leave no traces. Adequate inspection procedures may be difficult to establish, by Prof. S. Fred Singer, M/R Contributing Editor, 4/20/59, p. 26.

Radiation

RADIATION EFFECTS: WHAT'S BEING DONE? by Charles D. LaFond, M/R Associate Editor; 6/8/59, p. 37.

NEW DETAILS ON RADIATION; Staff Report; April 6; p. 40.

PARAFFIN WAX MAY BE BETTER FOR SHIELDING; Researchers feel hydrogen atoms in wax could absorb more neutrons than plastics, by W. C. Parle and A. M. Erskine, 3/16/59, p. 34.

RADIATION CAN BE AVOIDED; Van Allen advocates polar launchings; proposes that two radiation belts be mapped by 100-pound payload satellite, by Norman L. Baker, M/R Associate Editor, 1/5/59, p. 13.

INNER VAN ALLEN RADIATION BELT IDENTIFIED; Staff Report; 6/15/59, p. 39.

MANAGEMENT & GOVERNMENT

Air Force

AF SEES IMPROVED SYSTEM MANAGEM Weapon System Project Offices are repor getting the job done more efficiently alth there's still the problem of just when produ people should take over, by Betty Oswald, Associate Editor, 6/29/59, p. 35.

AF PUSHES RESEARCH ON DETONATION P LEM, by James Baar, M/R Associate Ed 6/15/59, p. 23.

U.S. DECIDES TO PUSH ALBM—'INVULNERA DEFENSE WEAPON; Douglas wins competition begins design study based on concepts tester Lockheed, Convair and Martin; GE said to guidance contract, by James Baar, M/R Asso Editor, 5/18/59, p. 19.

BOMARC WILL SOON MOVE INTO U.S. DEFENSE ROLE; Boeing surface-to-air missile to first base this fall, may displace Nikes, James Baar, M/R Associate Editor, 5/4/59, p.

THE DEATH OF A MISSILE; One of 40,000 fails and a 75-foot bird of space (Atlas) b up—pictures by Cornell Capa, story by Erica M/R Associate Editor, 5/4/59, p. 17.

ANDERSON PROMOTED FROM ARDC TO H AMC; Popular commander becomes a conte for chief of staff after hectic but rewarding ef to speed missiles, by James J. Haggerty, Jr., Contributing Editor, 3/9/59, p. 18.

Army

MEDARIS GIVES HIS BASIC PROCUREM PHILOSOPHY; M/R Staff, 6/29/59, p. 18.

ARMY EXPANDING BREAKOUT POLICY; Cong sees increased opportunities for small business Army taking "standardized" components a from primes and buying under competitive ding, by Erica Karr, M/R Associate Editor, 6/8 p. 13.

AOMC RECOMMENDS 'NO FUNDS' FOR MISS ABLE; Only 8 Lacrosse battalions; Prototype shing testing soon; Chrysler submits Jupiter target missile, by Donald E. Perry, M/R Man ing Editor, 3/30/59, p. 13.

ARMY IN THE SPACE BUSINESS (editori 2/2/59, p. 7.

ARPA

ARPA—A DANGEROUS COMPROMISE (editori 4/13/59, p. 11.

Budget

20 ICBM SQUADRONS IN BUDGET, M/R SI 2/2/59, p. 21.

BUDGET HOLDS $7 BILLION FOR MISSILES; $ million for space exploration; Minuteman, Ho Dog, Polaris, Nike-Zeus programs to be acce ated in $40 billion defense budget. ARPA we $455 million; NASA budget is $485 million, Clarke Newlon, M/R Executive Editor, 1/26, p. 21.

Congress

CAN CONGRESS DEFINE 'INFLUENCE'?; James Baar, M/R Associate Editor, 6/29/59, p.

CHAIRMAN SEEKS BROAD R&D POWER; R Overton Brooks feels his House group should h jurisdiction over all non-military research and velopment bills; sees this as step toward Dep ment of Science, by Erica Karr, M/R Associ Editor, 6/29/59, p. 32.

U.S. SEEKS WAYS TO CLOSE TRANSLATION G by James Baar, M/R Associate Editor, 5/25/ p. 35.

DEPARTMENT OF SCIENCE: STILL 'IFFY'; Hoov type commission recommended in Congressio hearings to decide how to centralize scattered forts in science, by Erica Karr, M/R Associ Editor, 4/27/59, p. 30.

MAHON TO DEMAND MORE ATLASES; by Jar Baar, M/R Associate Editor, 4/13/59, p. 34.

W PON SYSTEM CONCEPT FACES TRIAL; House gr p is set to quiz industry and Pentagon spokes- m in lengthy hearings airing charges of mon- o ization and profiteering, by James Baar, M/R A ciate Editor, 4/6/59, p. 15.

H SE GROUP URGES RELIABILITY PROGRAM; Jo is to recognize that reliability must be bal- and against other factors, by Betty Oswald, 4/ 9, p. 27.

U SURVIVAL IN THE ATOMIC/MISSILE AGE— T eminent lawmakers write their own widely di gent views on the Russian threat and how th U.S. should counter it. By Senator Stuart Sy gton and Rep. James G. Fulton, 3/30/59, p. 8.

PR CUREMENT OVERHAUL SOUGHT; Saltonstall bi aimed at cutting lead time and Pentagon re tape, has strong support in industry and a g some high DOD officials, by Erica Karr, M Associate Editor, 3/9/59, p. 39.

WH T WILL BE OUTCOME OF PROBE OF STL? C gress may recommend that STL sever all fi cial ties to Thompson Ramo-Wooldridge, and th a limit be placed on profits and salaries of co pany officials, M/R staff, 2/16/59, p. 13.

H SLE OVER SIZE OF RED LEAD; Five Con- g ional committees set to probe defense/space p grams, by Erica Cromley, 2/2/59, p. 13.

C NGRESS SEES URGENCY IN SPACE-MISSILE G LS, M/R Staff, 1/19/59, p. 18.

LE ISLATING FOR THE SPACE AGE (editorial), 1/ 59, p. 9.

R D REPORT SHOULD GUIDE 86TH CON- G SS; Soviet space lead estimated at 12 to 18 m ths; U.S. will require 5 years to catch up, C gress told, by Paul Means, M/R Associate Edi- to 1/19/59, p. 17.

C NGRESS SET FOR RENEGOTIATION FIGHT; I stry groups press for elimination of 17-year- o Act labeled costly and discriminatory, by E. . Halmos, M/R Contributing Editor, 1/12/59, p. 3.

O OSITION DEVELOPING TO PRESIDENT'S C NCIL; M/R Staff, 1/5/59, p. 14.

C NGRESS WILL KEEP EYE ON SPACE PRO- G M; New space committees being formed; I stry ready to battle for new renegotiation a by Erica Cromley, 1/5/59, p. 15.

Contracts

A IY EXPANDING 'BREAKOUT' POLICY; Con- is sees increased opportunities for small busi- e with Army taking 'standardized' components y from primes and buying under competitive b ling, by Erica Karr, M/R Associate Editor, 59, p. 13.

A ONG LOOK AT RENEGOTIATION (editorial), 59, p. 7.

N A PATENT RIGHTS DEBATED; Question is h much proprietary interest should space agency in over inventions performed under contract, staff, 6/1/59, p. 17.

L LINES FOR THE V-2; the need for less com- specifications (editorial), 3/23/59, p. 11.

N A, DOD HAVE WIDELY DIVERGENT PATENT H TS, 3/2/59, p. 14.

Financing

C ALLS OF MISSILE BUSINESS FINANCING; ewth can be deadly. But here's where to get tal—while you still can, an M/R staff report, /59, p. 17.

Industry

A MATTER OF THE MUNITIONS LOBBY (edi- al), 6/29/59, p. 7.

W KE UP AND LIVE; better communications by I stry essential (editorial), 6/22/59, p. 7.

E K. HOFFMAN RECEIVES M/R's GODDARD H PHY, M/R staff, 6/1/59, p. 23.

E DUCATE OUR YOUTH OR RUSSIA WILL; I stry urged to increase participation in scholar- awards (editorial), 4/20/59, p. 11.

E RGETIC CHAMPION OF THE COMPONENT R OACH, by Erica Karr, M/R Associate Edi- 4/6/59, p. 43.

HOFFMAN . . . THE POWER BEHIND ROCKET-DYNE, by Erica Karr, M/R Associate Editor, 3/23/59, p. 26.

LOCKHEED EMPHASIS IS SYSTEMS MANAGEMENT; Perfecting ability in systems management is setting pace at Lockheed Missiles and Space Division, by William O. Miller, M/R Associate Editor, 2/2/59, p. 16.

Missile Business—Outlook and Trends

DEFENSE CONTRACT PROFITS, by William E. Howard, M/R Associate Editor, 5/25/59, p. 50.

SPACE MARKET, by William E. Howard, M/R Associate Editor, 5/11/59, p. 49.

D-P's GROWTH; Daystrom-Pacific to Enter Systems Work, by Richard van Osten, M/R West Coast correspondent, 4/20/59, p. 34.

ESTIMATING MISSILE EXPENDITURES; Unfortunately there are no definitive answers; but with forward planning company resources could be directed to proper business success, by Douglas S. Evered, Missile Division, North American Aviation, Inc., 2/2/59, p. 26.

NASA

NASA PATENT RIGHTS DEBATED; Question is how much proprietary interest should space agency retain over inventions performed under contract, M/R staff, 6/1/59, p. 17.

NASA SPACE FLIGHT CENTER NAMED FOR GODDARD, 5/4/59, p. 38.

NASA MAY HAVE TO ASK FOR MORE FUNDS; Eight satellite launchings, 2 space probes and 45-50 sounding rockets may require additional funds above requested $485 million, M/R staff, 4/20/59, p. 24.

NASA EXPANDS NACA PROCUREMENT SET-UP; Procurement chief says agency is decentralizing contracting and prefers doing business with established companies, by Erica Karr, 4/6/59, p. 25.

HETS PROGRAM: SPACE COOPERATION (editorial), 3/9/59, p. 7.

SPACE 'PROGRESS' BY 1969? by Paul Means, M/R Associate Editor, 2/2/59, p. 25.

NATO

NATO MISSILE BUILD-UP AT STAKE: Outcome of East-West Conference over Russia's May 27 Berlin ultimatum will affect $1 billion in U.S. missile aid, by James Baar, M/R Associate Editor, 4/27/59, p. 13.

Navy

NAVY'S REORGANIZATION TO AFFECT RESEARCH; Rear Adm. Hayward—probably next DCNO—discusses what's needed from industry, by William O. Miller, M/R Associate Editor, 3/30/59, p. 24.

Pentagon—DOD

PRIORITY RULES ARE REVISED, by Betty Oswald, M/R Associate Editor, 6/29/59, p. 19.

THE NEW DEPUTY SECRETARY OF DEFENSE (editorial), 6/15/59, p. 9.

HOW IS DOD MOVING ON RELIABILITY? Some observers say it is in all directions but Air Force has come up with a new reliability monitoring system which should give better standards, by Betty Oswald, M/R Associate Editor, 6/1/59, p. 21.

PROPOSED—A UNIFIED STRATEGIC COMMAND (editorial), 6/1/59, p. 9.

THE NEXT DEPUTY DEFENSE SECRETARY (editorial), 5/18/59, p. 9.

CONCURRENCY—PRIME NEED IN PENTAGON (editorial), 5/11/59, p. 7.

WEAPON SYSTEM CONCEPT FACES TRIAL; House Group is set to quiz industry and Pentagon spokesmen in lengthy hearings airing charges of monopolization and profiteering, by James Baar, M/R Associate Editor, 4/6/59, p. 15.

QUARLES BEST TO REPLACE McELROY (editorial), 3/30/59, p. 7.

SOME VIEWS OF DOD RESEARCH CHIEF YORK; Pentagon's first R&E director gives priority to weapon system on basis of importance of its mission and encourages industry to do more research on its own, by Paul Means, M/R Associate Editor, 3/23/59, p. 21.

PROCUREMENT OVERHAUL SOUGHT; Saltonstall bill, aimed at cutting lead time and Pentagon red tape, has strong support in industry and among some high DOD officials, by Erica Karr, M/R Associate Editor, 3/9/59, p. 39.

THE NEW LINE-UP IN SPACE (editorial), 2/23/59, p. 9.

DOD CHIEFS BACK BUDGET: REGRET CUTS; Sentiment heavy in Congress for restoring many budgetary cuts, M/R staff, 2/9/59, p. 21.

NEITHER LIFE NOR DEFENSE ENDS AT 40 (editorial), 1/26/59, p. 11.

THE CASE OF DR. YORK AND MR. JOHNSON (editorial), 1/12/59, p. 57.

IDA'S 'BRAIN FACTORY' GUIDES WEAPON CHOICES; Five universities work with Pentagon to provide staff for secret projects, by E. E. Halmos, Jr., M/R Contributing Editor; 1/5/59, p. 20.

Procurement

MEDARIS GIVES HIS BASIC PROCUREMENT PHILOSOPHY, M/R Staff, 6/29/59, p. 18.

NASA EXPANDS NACA PROCUREMENT SET-UP: Procurement chief says agency is decentralizing contracting and prefers doing business with established companies, by Erica Karr, M/R Associate Editor, 4/6/59, p. 25.

PROCUREMENT OVERHAUL SOUGHT; Saltonstall bill, aimed at cutting lead time and Pentagon red tape, has strong support in industry and among some high DOD officials, by Erica Karr, 3/9/59, p. 39.

Renegotiation

A LONG LOOK AT RENEGOTIATION (editorial), 6/8/59, p. 7.

CONGRESS SET FOR RENEGOTIATION FIGHT; Industry groups press for elimination of 17-year-old Act labeled costly and discriminatory, by E. E. Halmos, M/R Contributing Editor, 1/12/59, p. 13.

Research

AF PUSHES RESEARCH ON DETONATION PROBLEM, by James Baar, M/R Associate Editor, 6/15/59, p. 23.

Russia

RED THREAT FROM ANTARTICA; U.S. and other nations are worried about Russian bases build-up and submarine missile launching potential, by James Baar, M/R Associate Editor, 6/1/59, p. 15.

SOVIET AFFAIRS; USSR plans scientific information center, by Dr. Albert Parry, M/R Contributing Editor, 6/1/59, p. 47.

SOVIET AFFAIRS; Soviet press evaluates U.S. missilery, 4/20/59, p. 48.

WHEN RUSSIA PUTS MEN IN SPACE (editorial), 4/6/59, p. 6.

SOVIET AFFAIRS; Russians claim space lead, by Dr. Albert Parry, M/R Contributing Editor, 1/12/59, p. 38.

WORLD MUST SOLVE BRAND NEW PROBLEM OF MOON RIGHTS; Authorities seeking answers find few precedents to work with and most consider U.N. control the most feasible, by Donald Cox, M/R Contributing Editor, 3/23/59, p. 24.

Taxes

WITH GOVERNMENT RECONSIDERING FAST TAX WRITE-OFFS, WILL 1959 BE 'BOOST' OR 'BUST' YEAR FOR SPACE RESEARCH? by William E. Howard, M/R Associate Editor, 4/20/59, p. 19.

Weapon Systems & WS Management

AF SEES IMPROVED SYSTEM MANAGEMENT; Weapon System Project Offices are reportedly getting the job done more efficiently although there's still the problem of just when production people should take over, by Betty Oswald, M/R Associate Editor, 6/29/59, p. 35.

HOW DO WE MAKE WEAPON SYSTEM INTEGRATION WORK? AF has established Project Offices with broad authority for overall management of all phases, by Betty Oswald, 6/15/59, p. 24.

STRATEGIC READY RESERVE STUDIED; Contractual personnel would maintain and operate complex weapon systems even in tactical use under proposed plans, by Donald E. Perry, M/R Managing Editor, 5/4/59, p. 13.

'FATHER' OF DYNA-SOAR AWAITS AF DECISION, by Erica Karr, M/R Associate Editor, 5/4/59, p. 29.

SMALL ALBM MAY GO ON F-10S; Republic's Mach 2 fighter may be built in Europe under NATO nations' share plan, by Clarke Newlon, M/R Executive Editor, 4/27/59, p. 14.

RELIABILITY IS OUR MOST IMPORTANT HEADACHE (editorial), 2/16/59, p. 7.

MATERIALS

Ceramics

MISSILE NEEDS POSE CHALLENGES FOR CERAMICS; Industry expects demand within decade for materials that will take temperatures up to 4000°F in missiles, by R. T. Inglis and D. L. Krout, Jr., 3/9/59, p. 34.

Connection (welding, etc.)

WELDING REDSTONE; Extreme care exercised at Reynolds plant precludes faulty welds, by M/R Staff, 6/8/59, p. 29.

Environmental Effects

SPACECRAFT MATERIALS PROBED BY SYMPOSIUM; by Frank McGuire, M/R Associate Editor, 5/25/59, p. 56.

IR ANALYZERS MONITOR GIANT WIND TUNNEL; by M/R Staff, 5/11/59, p. 41.

SOVIET AUTHOR WRITES ON THERMAL MATERIALS; by M/R Staff, 3/2/59, p. 29.

Explosive Forming

INDUSTRY PUTTING INCREASED EMPHASIS ON HEF PROCESSES; But the physical and metallurgical problems still remain largely unanswered with techniques being debated, by Frank McGuire, M/R Associate Editor, 5/6/59, p. 28.

Metals

BERYLLIUM STRUCTURE MADE; by M/R Staff, 6/8/59, p. 41.

NAA'S NOVEL APPROACH TO STAINLESS STEEL HONEYCOMB PANELS; Company sees "new era" in vehicle construction; process includes original heat-treating cycle, by Frank McGuire, M/R Associate Editor, 5/11/59, p. 23.

LOW COST BRAZED STEEL HONEYCOMB STRUCTURES; Martin's new hardened alloy solves problem of uneven filleting in brazing and allows opening of tolerances, by Clarence A. Boyce, Jr., Martin Co., 5/4/59, p. 33.

METALS CONGRESS DISCUSSES PROBLEM SOLUTIONS; Great strides reported in such fields as increasing metal strength and test methods, 3/23/59, p. 29.

'BREAKTHROUGH' IN TUNGSTEN FABRICATION; Fansteel research opens new applications for missile electronics, propulsion and structures, by Donald E. Perry, M/R Managing Editor, 3/23/59, p. 22.

Outlook

WHAT'S COMING IN MATERIALS RESEARCH? A leader in the field says costly and less glamorous production research has been neglected but novel techniques are being developed for fabrication and screening of new materials, by Arthur R. Lytle, Union Carbide, 4/6/59, p. 30.

HERE'S 1959 OUTLOOK FOR MISSILE MATERIALS; Metals will remain the mainstay, but competition from plastics will mean more teaming with ceramics, by Alfred J. Zaehringer, Associate Editor, M/R, 1/26/59, p. 24.

Plastics

SINGER'S CAST EPOXY RESIN MIRRORS REQUIRE NO COSTLY HAND WORK; Polishing and finishing eliminated in plastic replica process. Mirrors withstand 20,000g in shock tests, by M/R Staff, 3/2/59, p. 16.

MISSILES, SATELLITES & RESEARCH VEHICLES

Foreign Astronautics

REPORT FROM WEST GERMANY; Reds have "hundreds" of 700-mile missiles facing Western Europe; Germany would make Hawks under license; French atomic complaints, by Clarke Newlon, M/R Executive Editor, 6/29/59, p. 45.

BRITISH ASTRONAUTICS; More successful Seaslug trials; Rolls-Royce building Rocketdyne motors; Thunderbird comes into service with Army, by G.V.E. Thompson, M/R British Correspondent, 6/29/59, p. 28.

ON DISPLAY AT PARIS AIR SHOW; The Continent's biggest Space Age exhibition, by Jean-Marie Riche, M/R French Correspondent, 6/29/59, p. 24.

BRITISH ASTRONAUTICS; Government evasive on how much will be spent for space flight program; planetary probes and manned flight ruled out already, by G.V.E. Thompson, M/R British Correspondent, 6/8/59, p. 30.

SWISS FIRM TURNS OUT MOST MISSILES IN ITALY; Contraves AG developing into big supplier with its RSD-58 and RSC-57 missiles, by Anthony Vandyk, M/R Geneva Correspondent, 6/1/59, p. 22.

FRENCH ASTRONAUTICS; Air-to-Air and Ground-to-Air Missiles, M/R Paris Correspondent, 5/11/59, p. 19.

BRITISH ASTRONAUTICS; Progress on 24-channel time multiplex system; No decision yet on a British spaceflight programme; Blue Steel readied for test at Woomera, by G. V. E. Thompson, M/R British Correspondent, 5/11/59, p. 17.

FRENCH ASTRONAUTICS; S.E.P.R. test facilities are believed to be best on Continent; firm builds and tests both solid and liquid-fueled engines, by Jean-Marie Riche, M/R French Correspondent, 4/13/59, p. 28.

U.S. BUYING SS 10-11 FOR FORCES IN EUROPE, by Frank G. McGuire, M/R Associate Editor, 3/2/59, p. 32.

BLACK KNIGHT ENGINE DESCRIBED; by Anthony Vandyk, M/R Geneva Correspondent, 2/2/59, p. 24.

SEDOV COMPARES WEIGHTS OF U.S./SOVIET ROCKETS; M/R Staff, 2/2/59, p. 19.

EUROPEAN GROUP STUDIES BUILDING U.S. MISSILES; M/R Staff, 2/2/59, p. 21.

Research Vehicles

AEROJET'S NEW SOUNDING ROCKETS; Company is already taking orders for Astrobee series reportedly costing less than Aerobee but offering improved ease of handling, thrust alignment and attitude accuracy, by Frank G. McGuire, M/R Assistant Editor, 6/15/59, p. 25.

SCOUTING THE FRINGE OF SPACE; X-15 manned research vehicle rehearses for first flight, by Erica Karr, M/R Associate Editor, 6/1/59, p. 31.

NASA REPORTS SUCCESSFUL S-STAGE SOUNDING ROCKET, M/R staff, 4/13/59, p. 38.

X-15 DROP SOON; Guidance to be tested in early phase, 2/16/59, p. 26.

Satellites

VANGUARD ORBIT TRY FAILS AS REGULATOR BREAKS DOWN, M/R staff, 6/29/59, p. 33.

NASA SPACE LAB PLANS OUTLINED; ARS r... ing also hears debate on the long-term val... Project Mercury holding facility' and report ... ramjet, ion engine and APU developments ... Frank G. McGuire, M/R Associate Editor, 6/2... p. 24.

U.S. MAY SEEK PACT TO SILENCE OUTW... SATELLITES; Delegation at Geneva meeting ... also propose radio frequencies to be reservec... space use only, by Paul Means, M/R Asso... Editor, 6/1/59, p. 24.

ABMA RECEIVES FIRST OF SATURN ENGI... Jupiter test stand being modified to accommo... cluster of Rocketdyne H-1 liquid engines, ... staff, 5/25/59, p. 36.

ADAM MAKES COMEBACK IN MERCURY,... Paul Means, M/R Associate Editor, 5/4/59, p. ...

DISCOVERER, YES; VANGUARD, NO! Polar s... lite capsule is believed to have reentered; r... netometer try invalidated by second stage tro... 4/20/59, p. 22.

EXPLORER V WILL CARRY HIGHLY COMI... PAYLOAD; by Paul Means, M/R Associate Ed... 3/27/59, p. 20.

DISCOVERER I ORBIT DUBIOUS; Intermittent ... nals may be caused by satellite's tumbling ... solar heat reviving cold batteries, M/R s... 3/9/59, p. 20.

PIONEER DEVIATES IN TRAJECTORY; But ... stage Jupiter fired perfectly with less than ... second lift-off delay by ABMA team, by ... Means, M/R Associate Editor, 3/9/59, p. 20.

WEATHER SATELLITE WILL HAVE THREE C... ERAS; Later meteorolgical experiments will ... responsibility of Weather Bureau Section, by F... G. McGuire, M/R Associate Editor, 3/2/59, p...

REDS SAY LUNIK MADE 'COMET,' by Frank ... McGuire, M/R Associate Editor, 2/23/59, p. 3...

SCOUT COULD ORBIT 150 LBS, M/R staff, 2/16... p. 13.

U.S. RESEARCH AIMS AT SPACE LAB, by Cl... Newlon, M/R Executive Editor, 2/2/59, p. 12.

RE-ENTRY NAVIGATION: 'BREAKTHROUGH' ... NOT REQUIRED, by Raymond M. Nolan, ... Associate Editor, 1/26/59, p. 29.

LOCKHEED SPACE STATION INTERESTING ... AGENCIES; Satellite Laboratory could be in... eration in 10 years; Cost estimate put at $... billion, by Norman L. Baker, M/R Associate Ed... 1/19/59, p. 19.

STANDARD NAVIGATION AIDS COULD GU... SPACE TRAVEL; M/R staff, 1/19/59, p. 27.

LUNIK BECOMES SOLAR SYSTEM'S Tenth "Plan... Indications are Russians may have hoped to ... moon; exploit demonstrates know-how in velo... guidance, by Norman L. Baker, M/R Assoc... Editor, 1/12/59, p. 21.

USSR LUNAR PROBES WILL ORBIT CLOSE ... SURFACE. By Lt. Cmdr. John A. Fahey, U.S. N... Intelligence School, 1/12/59, p. 22.

MISSILE SUPPORT

Electronics

ELECTRONIC OUTPUT TO DOUBLE BY 1... What's the future for electronics in MSE? ... William E. Howard, M/R Associate Editor, 5/25... p. 25.

General

THE GOLDEN FIELD OF MISSILE SUPPORT (... torial), by Clarke Newlon, M/R Executive Edi... 5/4/59, p. 6.

ARS MEETING STRESSES GROUND SUPP... EQUIPMENT; Pre-launch problems, data hand... and missile performance comes up in techn... papers delivered by specialists, by William ... Miller, M/R Associate Editor, 3/30/59, p. 16.

Launching Facilities

HOW TO HANDLE 24-MEG THRUST; Special ... istics will be needed for 1.5 million pounds-... boosters, by Chauncey J. Hamlin Jr., North Am... ican Aviation, 6/29/59, p. 16.

FBM SUB PROVIDES NEW MARKET; With 45 mi-launching boats possible, lion's share of om $4.5 billion should go for support equipment, by onald E. Perry, M/R Managing Editor, /8/ , p. 31.

MIN TEMAN RAIL CONCEPT PUSHED; 200 missile trai appear possible which should open up a who new field of missile support equipment run g into multi-million dollar program, by Wil lian E. Howard, M/R Associate Editor, 6/1/59, p.

U.S SEEKS MANUS LAUNCH SITE; ARPA has eng ering plan to spend millions on tying island into PMR; NA5A may help in development of site hen selected, by William E. Howard, M/R Ass ate Editor, 5/18/59, p. 21.

BIL ONS FOR ICBM LAUNCHING FACILITIES; Air orce wants $343 million in FY '60 alone to har Atlas and Titan bases . . . advent of Mineman will swell outlay, by William E. How d, M/R Associate Editor, 5/11/59, p. 13.

CA OPERATING AT ONE-FIFTH CAPACITY, by M/ Staff, 5/4/59, p. 36.

PM INVESTMENT TO REACH $250 MILLION IN 196 Extra $75 million probably will be funded n xt two years for base construction, by Robert Mo , 4/13/59, p. 36.

A RD LOOK AT SPACE LOGISTICS; AF-spon or conference told it may be 5-10 years before ma an be kept alive in space; planners banking on etter component reliability, by William O. Mil , M/R Associate Editor, 4/6/59, p. 17.

ATI BASES TO BE HARDENED; Titan and Atlas will both be continued, Pentagon tells Congress, but omarc sites are cut sharply, by James Baar, M/ Associate Editor, 3/30/59, p. 15.

WOLD RAPIDLY ADDING MORE MISSILE LA ES; United States is negotiating in hopes of operation in man-in-space plans. Existing an s very from relatively small facilities to those ex ding thousands of miles. Small nations are par ipating at a fast-growing rate, by William O. iller, M/R Associate Editor, 3/9/59, p. 15.

Production Facilities

PI FORGE FORMS STEEL ONE INCH THICK, y I/R Staff, 3/23/59, p. 31.

HE ROBOT IS BIG STEP IN NUMERICAL CON RO; Automatically programmed tool developed t IT translates jargon and guides cutting, by an J. Haggerty, Jr., M/R Contributing Editor, /59, p. 33.

HO IRBM PRODUCTION; by Fred S. Hunter, M/ Associate Editor, 2/16/59, p. 15.

UI ER IRBM PRODUCTION; by Alfred J. Zaeh ne , M/R Associate Editor, 2/16/59, p. 18.

Research Facilities

IC BIG A MISSILE SUPPORT FILE? AF list il tart with some 2500 data sheets but opinions iff on how much longer it will get, by William oward, M/R Associate Editor, 6/22/59, p. 13.

F CATALOGUING SUPPORT ITEMS; Massive ol e due July 1 should save millions in waste l development of redundant equipment and od standardize handling and checking-out ea by William E. Howard, M/R Associate di , 6/15/59, p. 21.

Society

FEAM SEEKS SAFER MISSILE FLIGHTS; GM8 ro is handicapped by sparse data but hopes to velop a central report procedure, by Richard arOsten, M/R Associate Editor, 4/27/59, p. 28.

HT WILL BE NEEDED IN MSE—WHEN MAN NRS THE MISSILE, by Hal Gettings, M/R ssiate Editor, 4/20/59, p. 20.

Budget Facilities

DU COMPANIES PRODUCING VERSATILE R ES; Bendix, Republic and Marquardt joined rs in designing ground-launched Hilo, pro d a bomber-like radar image. Bell worked t Bendix in developing Penny, air-launched to erm at high altitude and supersonic speeds, Frank G. McGuire, M/R Associate Editor, 59, p. 21.

Test and Checkout

ATLAS PARTS TEST STAND PRODUCED BY ROCKETDYNE; by M/R Staff, 6/8/59, p. 32.

A MAMMOTH GANTRY FOR SATURN; Structure will cost $9.5 million with test tower, opening new dimension in missile support equipment, by M/R Staff, 6/8/59, p. 33.

VIBRATION TESTING OF NEW MISSILES SAVES MONEY AND TIME; Trend is toward more accurate reproduction of effects of dynamic forces, using such equipment as Ling's spectral density analyzer system, by Cameron G. Pierce, 4/27/59, p. 17.

VANGUARD TESTING: BACKBONE OF PRESENT BALLISTIC MISSILE ART; Checkout 'primer' developed by Martin gives pattern for industry to follow, by William E. Howard, M/R Associate Editor, 4/6/59, p. 20.

TITAN'S TESTING TIME MAY BE ONE HALF ATLAS'; SAC personnel to join Martin's streamlined test division in September; static firings may be eliminated at Cape, by Donald E. Perry, M/R Managing Editor, 3/16/59, p. 22.

COOK LABS DO MASS COMPONENTS TESTING; Inland testing engineers screen up to 100,000 parts simultaneously without damaging those that are acceptable, by M/R Staff, 2/23/59, p. 24.

BOMARC ENGINES ARE TESTED AT MARQUARDT LAB; Huge facility stores fifty tons of air for supersonic testing at altitudes near 200,000 feet, by Raymond M. Nolan, M/R Associate Editor, 1/12/59, p. 15.

Test Ranges

A CRISIS IN RANGE INSTRUMENTATION; AFMTC commander says more funds and effort must be expended to cure the rapidly widening time bottleneck, by Maj. Gen. Donald N. Yates, 6/29/59, p. 20.

Tracking

NEW AMPLIFIERS EXTEND MISSILE TRACKING RANGE; by M/R staff, 3/23/59, p. 41.

3000-MILE RADAR MAY BE ON TRACKING SHIP; by Peer Fossen, M/R Associate Editor, 2/2/59, p. 32.

Transportation

GOODYEAR'S APPROACH FOR ATLAS MSE; by M/R Staff, 4/20/59, p. 23.

NYC TESTS MISSILE TRANSPORT; by Frank G. McGuire, M/R Associate Editor, 2/2/59, p. 19.

PROPULSION

Controls

THROTTLEABLE ENGINE PROLONGS AIRCRAFT LIFE; Rocketdyne's AR series with up to 6000-lb thrust is ready for use although Navy has cancelled program, by Frank G. McGuire, M/R Associate Editor, 4/27/59, p. 23.

COMPLICATION FOR SOLIDS: THRUST-DIRECTION CONTROL; Ballistic missiles will require thrust vector control, thrust termination, thrust modulation, by Norman L. Baker, 2/9/59, p. 23.

Cryogenics

PROPULSION ENGINEERING; New plant turns out 'purest hydrogen ever made', by M/R staff, 6/8/59, p. 45.

FLUORINE ENGINES MAY ARRIVE WITHIN FIVE YEARS; Dramatic increase in rocket capability will come when compatible materials are developed. Fuel supply considered more than adequate, by Paul Means, M/R Associate Editor, 5/11/59, p. 42.

VACUUM JACKETING CUTS FUEL LOSSES; CEC reports its jacketed lines reduce boil-off by half, compared to those insulated with other materials, M/R staff correspondent, 4/6/59, p. 22.

Hybrids

PROPULSION ENGINEERING; Advantages of hybrid nuclear-chemical rocket engines, M/R staff, 5/18/59, p. 52.

Liquid

PROPULSION ENGINEERING; Ammonium nitrate as oxidizer, M/R Staff, 4/27/59, p. 49.

BRITISH ASTRONAUTICS: British firm starts manufacture of hightest hydrogen peroxide, by G. V. E. Thompson and K. W. Gatland, M/R Contributing Editors, 4/6/59, p. 19.

PROPULSION ENGINEERING; Boron fuels, M/R Staff, 3/16/59, p. 40.

ARMOUR ENTERS EMPIRICAL ROCKET APPLICATIONS, M/R staff, 3/2/59, p. 18.

FUELS VAPORIZATION STUDY CONTRACT AWARDED BY NSF, M/R staff, 2/23/59, p. 56.

PROPULSION ENGINEERING; Pre-packaged liquid propellant announced by Navy, by Alfred J. Zaerhringer, M/R Associate Editor, 2/9/59, p. 106.

1-1.5 MEG ENGINE MAY BE OPERATIONAL IN SIX YEARS, M/R staff, 2/2/59, p. 20.

Nuclear

PROPULSION ENGINEERING; Vary thrust for optimum nuclear rocket performance, M/R Staff, 6/1/59, p. 45.

AEC IS RECOVERING VALUABLE CERIUM 144, M/R staff, 4/13/59, p. 38.

PROPULSION ENGINEERING; Aerojet's head questions nuclear rocket's practicality, M/R staff, 4/6/59, p. 47.

THE NEGLECTED ATOMIC PROPULSION PROGRAM (editorial), 3/2/59, p. 7.

GE SCIENTISTS DESCRIBE NUCLEAR POWER PACKAGE, M/R staff, 1/5/59, p. 30.

Outlook

INDUSTRY TELLS CONGRESS: DO MORE BASIC RESEARCH NOW, by William E. Howard, M/R Associate Editor, 3/30/59, p. 20.

CHEMICAL INDUSTRY EXPANDS FOR ASTRONAUTICS, by Alfred J. Zaehringer, M/R Contributing Editor, 2/2/59, p. 28.

Plasma

PLASMA ENGINE DELIVERS NEARLY 2 LBS; M/R staff, 6/8/59, p. 34.

Solids

PROPULSION ENGINEERING; Basic studies on plastics will give propulsion engineers more solid propellant data, M/R Staff, 6/22/59, p. 45.

COMPLICATION FOR SOLIDS: THRUST-DIRECTION CONTROL; Ballistic missiles will require thrust vector control, thrust termination, thrust modulation, by Norman L. Baker, M/R Associate Editor, 2/9/59, p. 23.

SPACE MEDICINE

Animal Experiments

PIONEERING MONKEYS AND MICE; Two monkeys come back strong from Jupiter flight, though one dies later; Discoverer III tests will be U.S.'s most elaborate effort, by James Baar, 6/8/59, p. 28.

SPECIAL PROBLEMS OF THE MONKEY-IN-SPACE, by Dr. Earl T. Carter, Ohio State University, 5/11/59, p. 30.

Human Engineering

ADAPTING MAN TO HIS LIFE IN SPACE, by James Baar, M/R Associate Editor, 6/29/59, p. 22.

SPACE FEEDING: BIG $$ MARKET; Air Force contracting with industries on four lines of space food with bulk of work being handled through Quartermaster Food and Container Institute, by James Baar, M/R Associate Editor, 6/15/59, p. 28.

SPACE MEDICINE PROBLEMS PROBED BY AMA, by Frank G. McGuire, M/R Associate Editor, 5/11/59, p. 22.

CONVAIR INVESTIGATES ENVIRONMENTAL TOLERANCES, M/R staff, 2/9/59, p. 63.

Space Capsules

AN EXCLUSIVE INTERVIEW WITH THE AF SPACE MEDICINE CHIEF; Dr. Hubertus Strughold looks beyond Project Mercury to time when space flights may last months, 3/30/59, p. 22.

McDONNELL GETS MERCURY AWARD; by Clarke Newlon, M/R Executive Editor, 1/19/59, p. 18.

STRUCTURES

Astrodynamics

DRAG BRAKE PROPOSED FOR M-I-S, M/R Staff, 6/22/59, p. 18.

Components

THE CASE FOR COMPONENTS RESEARCH, by Charles D. LaFond, M/R Associate Editor, 4/6/59, p. 22.

Design

NOTCH SENSITIVITY WALL WILL CRACK, M/R Staff, 6/22/59, p. 15.

DETAILS OF ATLAS CONSTRUCTION DISCLOSED, M/R Staff, 6/1/59, p. 26.

Nose Cones

BIRTH OF A TITAN NOSE CONE, M/R Staff, 5/11/59, p. 32.

SPRAYING TECHNIQUE MAY CUT RADOME COST, by Richard Van Osten, M/R Associate Editor, 3/16/59, p. 37.

THE CASE FOR ABLATION, by Henry G. Lew, Sinclair M. Scala and George W. Sutton, 6/8/59, p. 19.

THE CASE FOR HEAT SINK, by Dr. J. D. Stewart, 6/8/59, p. 16.

Test

WEAPONS TESTING BOOMS AT AF'S ARNOLD CENTER, M/R Staff, 3/9/59, p. 31.

ARGMA'S PLASMA JET TEST FACILITY IN OPERATION; Prototype model for aerodynamic heating tests reaches 50,000° fusing argon gas with 13,000 fps flow rate, by M/R Staff, 3/23/59, p. 39.

THE DEATH OF A MISSILE; One of 40,000 parts fails and a 75-foot bird of space (Atlas) blows up—pictures by Cornell Capa, story by Erica Karr, M/R Associate Editor, 5/4/59, p. 17.

VIBRATION TESTING OF NEW MISSILES SAVES MONEY AND TIME; Trend is toward more accurate reproduction of effects of dynamic forces, using such equipment as Ling's spectral density analyzer system, by Cameron G. Pierce, 4/27/59, p. 17.

VANGUARD TESTING: BACKBONE OF PRESENT BALLISTIC MISSILE ART; Checkout 'primer' developed by Martin gives pattern for industry to follow, by William E. Howard, M/R Associate Editor, 4/6/59, p. 20.

TITAN'S TESTING TIME MAY BE ONE HALF ATLAS'; SAC personnel to join Martin's streamlined test division in September; static firings may be eliminated at Cape, by Donald E. Perry, M/R Managing Editor, 3/16/59, p. 22.

COOK LABS DO MASS COMPONENTS TESTING; Inland testing engineers screen up to 100,000 parts simultaneously without damaging those that are acceptable, by M/R Staff, 2/23/59, p. 24.

BOMARC ENGINES ARE TESTED AT MARQUARDT LAB; Huge facility stores fifty tons of air for supersonic testing at altitudes near 200,000 feet, by Raymond M. Nolan, M/R Associate Editor, 1/12/59, p. 15.

missile business . . .

By WILLIAM E. HOWARD

Multi-million dollar savings . . .

are envisioned through proposed electronic data processing of DOD's worldwide logistics operation. High speed equipment would be utilized to keep up-to-the-minute records of the thousands of parts and design changes in missile/aircraft and other weapon systems. AIA reports the plan will be submitted to DOD next month. It was devised by a Military/Industry Logistics Data Development Unit (MILDDU) after a 10-month study determined that a single data exchange system could be designed using a standardized punch card record length as the base for development.

Meantime, just such a "push-button" . . .

delivery system has been developed at Warner Robins Air Materiel Area, Robins AFB, Ga., to support *Mace* installations. **Goodyear Aircraft,** which recently received a $302,000 *Mace* warehousing order from Warner Robins and has the complete support contract for the **Martin**-built missile as well as its guidance system, says the new electronic logistic system is called MAST (missile automatic supply technique). Designed to eliminate slow-moving paperwork, MAST absorbs data on component usage over a global network in seconds. The data is code-punched at supply depots and transmitted to Warner Robins.

Inventories are instantly computed . . .

at headquarters and orders issued to warehouse points or manufacturers to ship required parts and supplies. The concept amounts to a supply sergeant's dream come true. No forms. Just punch a button and wait for the stuff to arrive on the next plane.

Goodyear says the MAST system has been thoroughly tested and presently is being put into operation to control *Mace* logistics primarily at launching and supply depots of the Tactical Air Command in Europe. Squadrons of the 800-mile range *Mace* are now replacing the shorter range *Matador.*

An automatic production and inventory . . .

control system is helping keep kinks out of operations at the **Rocketdyne Division of North American Aviation.** The company says the newly-installed Mechanized Production Control (MPC) system gives management a daily report on all rocket engine manufacturing activities. Moreover, it "immediately calls out corrective action for all behind-schedule parts or components."

Rocketdyne Factory Manager Ross Clark . . .

says with MPC company business is administered at considerably less cost and with greater accuracy. Here's the way it works: employing automatic tabulating machines, MPC established schedules on all production activities, starting with engineering drawings. Then, automatically, engineers are notified when to release the drawings, the purchase department is notified when to buy parts or material, and production departments are informed when they will receive the parts and given a completion date. All activities leading to engine fabrication are pre-scheduled and all components and parts are detailed on a master list.

"Move cards" keep track of progress on parts and components as they move through production departments. Information from these cards is fed into electronic accounting machines, which then compile reports listing the production status of all parts.

Benefits of the system, says Clark . . .

include reduction of production lead time, reduction of work that is behind schedule and the maintaining of accurate up-to-the-minute inventories. He says MPC is, indeed, one of the company's "most important new programs."

ppointment of **Samuel W. Stewart** as director of engineering and research at the Gabriel Electronics Division was announced. Stewart was formerly head of the Microwave Engineering Department at the Sperry Gyroscope Co., where he was in

TEWART

ge of research-through-production of icrowave components, antennas and an- ent systems.

verett B. Boise, former supervisor of pplications engineering, production types, as been elevated to manager of applica- io engineering, receiving tubes, for E Hytron. Boise is a graduate of Rens- el r Polytechnic Institute and has served s n engineer with the RCA patent de- artment license division, and as chief o mercial engineer for National Union Ra o Corp.

Tasker Instruments Corp. recently ai ed **David J. Green,** vice president for Ad nced Systems Development to direct x ratory programs into advanced R&D o epts and systems design. Green comes o Tasker from the System Development Co., formerly a division of the Rand Co., where he was head of Corporate Ad nce Planning and served as a mem- e of the management committee.

Dr. David M. Heinz has been named s nior scientist at Hoffman Electronics Co.'s new Science Center in Santa Ba ara, Calif. He will concentrate on er conductor materials and in the field f general chemistry. Dr. Heinz was o erly a physicist in the materials and pr esses unit of General Electric's In- tr ent Department, and a research as- o te in the GE Research Department's Ge al Physics Research Laboratory.

Dr. Robert E. Samuelson has been appointed to the newly created post of assistant general manager for research and development at Motorola's Western Military Electronics Center in Phoenix. With Motorola since 1950, Dr. Samuelson has been successively

AMUELSON

se r project leader, chief engineer and en neering manager of the Military El tronics Center in Phoenix.

Dynatronics, Inc., Orlando, Fla., has pr oted former vice president and chief en neer **George F. Anderson** to vice president and general manager. The firm is engaged in R&D and production of space communication, data handling and specialized test equipment.

Epsco, Inc.'s new subsidiary, Monitor Systems Inc., will be headed by **Harry H. Rosen.** Rosen is former manager of Data Processing and Computation in G.E.'s Missile and Space Vehicle Department. MSI expects eventually to employ several hundred engineering, production, and management personnel from the Philadelphia area.

William R. White, acting general manager, takes over as president of U.S. Semiconductor Products, a division of Topp Industries, Inc. **Dr. Friedrich Schwarz,** who has headed the company since its beginning two years ago, has been elected chairman of the board of directors. In addition to his new assignment, Schwarz will be active in the research and development programs of other Topp divisions—U.S. Science and Micro-Path.

Other officers in the company will include **Robert Rutherford,** vice president and director of engineering, and **Gayle Hodges,** secretary-treasurer. Reorganization of the U.S. Semcor management team came one week after finalization of its acquisition by Topp.

PHILLIPS

Alvin B. Phillips has been appointed chief engineer of Motorola's Mesa transistor product line. Phillips is a former marketing product planner with General Electric's Semiconductor Products Department.

Carl E. Calohan was appointed advertising and sales promotion manager of Giannini Controls Corp., succeeding **Richard L. Lawrence,** who resigned to accept a similar position with Hughes Semiconductor Products.

Glen P. Bieging has been named manager of marketing for General Electric Co.'s Missile and Space Vehicle Department. He was manager of market research and product planning for the G.E. Heavy Military Electronic Department in Syracuse.

Allan F. Donovan, vice president and director of Advanced Systems Planning at Space Technology Laboratories, Inc., has been named a delegate to a panel of technical experts which will advise the U.S. Committee on Nuclear Testing. He will counsel the Committee on the possibilities of using space vehicles to carry out undetected nuclear tests in outer space. Donovan joins the eight other members of the panel headed by **Dr. Wolfgang K. H. Panofsky,** of Stanford University, in Geneva to begin discussions with similar groups of British and Russian experts.

Hal V. Miller was named liaison engineer at Packard Bell Electronics Corp.'s Technical Products Div.

New manager of the Space Technology Laboratories Field Office at Warren AFB, Cheyenne, Wyo., is **W. H. Edwards.** He has been with STL since September, 1955, and played a prominent part in the firm's *Atlas* ICBM work.

ANALYTICAL ENGINEERS

career opportunities with an expanding facility in New England . . .

Requirements: BS in Mechanical Engineering or AE degree, 2-5 years experience in one or more of the following: 1) small turbo-machinery (compressor, turbines, fans) 2) lightweight heat exchangers 3) thermodynamic cycle analysis 4) air conditioning, air and vapor cycle refrigeration.

Duties: Work includes both applied theoretical and experimental analysis starting with initial design and continuing through prototype. Involves performance computation defining configurations of components and complete systems to meet specifications. Opportunity to utilize IBM 704 and 705 for complex methods of analysis.

Join a technical group whose facilities and background knowledge are unrivalled in the industry. Your talents will be employed in the development of advanced concepts, and also in internal consulting work on problems encountered by the Design and Development Engineering Groups.

Very pleasant urban or suburban living conditions . . . opportunity for tuition-paid post graduate study . . . generous relocation allowance.

This Division of United Aircraft is now actively engaged in product diversification and development of jet aircraft equipment, ground support equipment and missile components.

Panels Reportedly Solve Radar Van Heat Problems

FULLERTON, CALIF.—Ground systems engineers at **Hughes Aircraft Company** report that they have devised a low-velocity air diffusion panel to solve the ticklish heat problem in close quarters of new mobile radar vans designed to detect enemy missiles.

In designing and producing "3-D" radar mobile control vans, Hughes was faced with the problem of cooling both the myriad electronic equipment and the seven operators in the compact vehicles, it was reported by Wayne Stauch, Hughes mechanical engineer.

In addition to the fact that the van ceiling is only three inches above the head of the average operator, the problem was compounded by the limitation of diffusion space to a narrow central "corridor," Stauch said.

Finding that standard high velocity air diffusion was unsatisfactory from both a draft and noise standpoint, project engineers found a solution after testing the comparatively new concept of low-velocity diffusion.

The air diffusers used consist of panels with a perforated distribution plate which, by means of a pressure displacement valve, slows down the speed of the cool air and diffuses it evenly throughout the air conditioned area. The air is brought to the panels from the cooling source through the plenum above the van ceiling.

Stauch points out that depending upon the size of the van, up to three pairs of valves are used. The air flow can be regulated by a valve adjustment.

The special ventilation product used to solve the problem, Stauch reports, was the Multi-Vent panel, produced by the **Pyle-National Company,** Chicago, developers of the low velocity diffusion method.

Originally designed by Pyle-National to solve similar problems in railroad passenger cars, the technique has in recent years been used for air conditioning office buildings, computer rooms, and general commercial and institutional applications.

The product is also beginning to receive attention, he said, for mobile homes, office trailers, submarines, ocean going passenger vessels, and other uses where space limitation is a problem.

Solids Seen as Good Source for AP

SAN DIEGO—Solid propellants can be a versatile efficient source of power for many space flight purposes besides rocket propulsion.

Two Washington, D.C., scientists told the recent American Rocket Society meeting here that gas turbines fueled by solid propellants can drive electrical generators, mechanical and exhaust systems and perform several other functions.

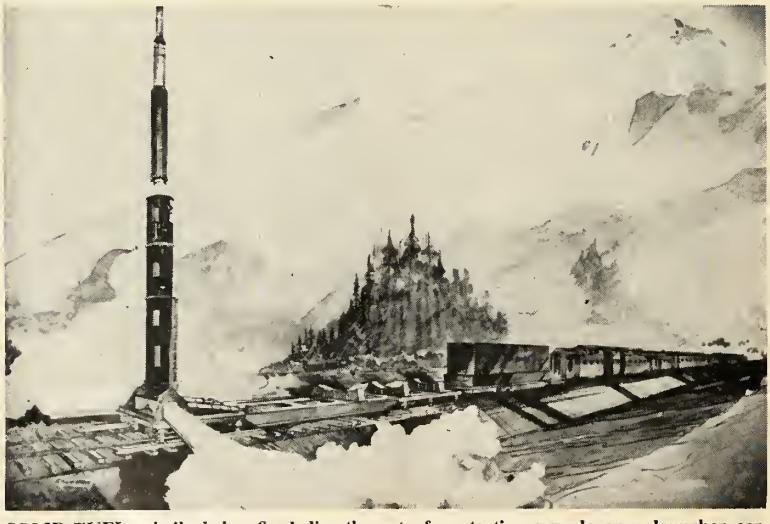
Melvin Cohen, of the Hicks Corp., and Lt. Com. Edward J. Sheeh the Navy Ordnance Bureau, said power can be used in a missile electronic and guidance systems, dynamic and flight control sys and separation and termination de

Missile designers have many so of power available. Four of the common are batteries, bottled pressed gas, liquid-propellant gas erators and solid-propellant gas g ators. Cohen and Sheehy outlined advantages and disadvantages:

Batteries—Use limited by exce weight and size as against power put.

Bottled gas—Heavy inert ponents necessitated by high gas sures; excessive space requirement cause of low density.

Liquid-propellant generators— ter than batteries or bottled gas many purposes but more com bulkier and less reliable than solid pellant generators.



The solid-propellant generator one major limitation. It is inher a "one-shot" operation. It is not tical to turn a solid propellant off on again, although some work is done in smothering the fire before charge is completely burned up.

• **In an emergency**—Cohen the solid-propellant turbine prot never would compete with solar teries for such long-term low- power uses as light, heat and needs aboard a manned space But he said such a turbine woul valuable for emergency use while ing repairs on regular power sou He compared this to the auxi power supply in a hospital basen for use in case the city supply i terrupted.

In the laboratory, experim units have supplied gas-turbine p for periods of time on the order o to 20 minutes, Cohen reported. noted that this is nearly the maxi duration of an ICBM flight. The b ing is prolonged on essentially same principle as in a cigarette- packing the propellant in a long, row cylinder. It may be curled, ever, for convenience.

Several missiles already use s fuel gas turbines, Cohen declared. their use is growing rapidly. One missile has a turbine of this type can run an electrical generating tem from 60 to 90 seconds, more enough time to last the one-mi flight. A second turbine runs hydr equipment for about the same pe of time. Cohen declined to identify missile beyond saying it is in the class (*Talos, Terrier* and *Tartar*). added that such devices are also in in one British missile and in a h speed Navy torpedo.

Launching from Railroad

SOLID-FUEL missile being fired directly out of protective capsule on a launcher car, preliminary designs for which have been made jointly by Bethlehem Steel Co. and Paul Hardeman, Inc. Flame at the bottom is deflected by outstretched shields in this artist's conception. Hydraulic jacks, carried under car, push steel beams down over ties to stabilize the car. (See M/R, June 1, page 19).

3,712—Ordnance Specialties, Inc., El onte, Calif., for a powder actuated eefing line cutter.

000—Thompson Ramo Wooldridge, Inc., os Angeles, for telemetering system de- elopment.

166—Tele-Dynamics Inc., Philadelphia, r services consisting of the manufacture f telemetry transmitting systems, com- onents, assemblies and sub-assemblies, nd the modification and testing thereof.

167—Kin-Tel, Div. of COHU Electronics, an Diego, for amplifiers.

372—Hallamore Electronics Co., Ana- eim, Calif., for cameras and accessories.

838—Helge Olsen Inc., East Orange, N.J., r pyrotechnic area, facilities and utili- es, additional altitude test chamber at icatinny Arsen, Dover, N.J.

935—RIAS, Div. of Martin Co., Balti- nore, for research and development on he effects of surface films on the me- hanical properties of metals.

065—Resdel Engineering Corp., Pasadena, alif., for receivers and oscillators.

NAVY

000,000—Autonetics Div. of North Ameri- an Aviation, Inc., for electronic arma- ent control systems for the Republic of Vest Germany (subcontract from Lock- eed Aircraft Corp.).

$2,000,000—Convair Div. of General Dynamics Corp., San Diego, for design and manufacture of a radar for navigation-bombing, system (subcontract from Autonetics Div. of North American Aviation, Inc.).

$1,500,000—Melpar, Inc., for production of target detecting devices for the *Talos* surface-to-air missile.

$1,241,057—Federal Pacific Electric Co., Newark, N.J., for missile and *Asroc* fire control switchboards.

$980,000—Summers Gyroscope Co., Santa Monica, Calif., for high performance gyros to be used in the *Terrier* and *Tartar* missiles (subcontract from Convair Div. of General Dynamics).

$760,000—Westinghouse Electric Corp., Baltimore, for production of electric propulsion motors to be used in the anti-submarine torpedo, the Mark 37.

$182,500—Telemeter Magnetics, Inc., Los Angeles, for research and development of magnetic core memory.

$166,347—General Electric Co., Syracuse, N.Y., for research on defense against ballistic missiles.

$143,007—Aeronutronic Systems, Inc., Glendale, Calif., for research on defense against ballistic missiles.

$128,079—Convair Div. of General Dynamics Corp., San Diego, for research on ballistic missile defense.

$121,061—Allied Research Associates, Inc., Boston, for research on defense against ballistic missiles.

$117,783—Hnghes Aircraft Co., Culver City, Calif., for research on defense against ballistic missiles.

$96,225—University of Chicago, for research on defense against ballistic missiles.

$25,041—Winzen Research, Inc., Minneapolis, for research on defense against ballistic missiles.

$25,000—Armour Research Foundation of Illinois Institute of Technology, Chicago, for research on high powered transducers.

AIR FORCE

$722,413—General Petroleum Corp., Los Angeles, for 6,453,000 gallons of rocket fuel.

$623,201—Litton Industries, Electron Tube Div., San Carlos, Calif., for miscellaneous electron tubes.

$500,000—United Electrodynamics, Pasadena, Calif., for an FM/AM telemetry system used in research and development flight tests of the *Minuteman* missile (subcontract from Boeing Aircraft Corp.).

$395,404—Tidewater Oil Co., Los Angeles, for 2,524,000 gallons of rocket fuel.

$315.557—Bell Oil and Gas Co., Tulsa, for 1,757,000 gallons of rocket fuel.

$175,393—Photo-Sonic, Inc., Burbank, Calif., for 18 35-mm high-speed motion picture cameras.

$131,313—Tung-Sol Electric Inc., Newark, N.J., for miscellaneous electron tubes.

$136,710—Eitel-McCullough, Inc., San Bruno, Calif., for miscellaneous electron tubes.

$70,304—Allen B. Dumont Labs, Inc., Clifton, N.J., for miscellaneous electron tubes.

$48,000—Waste King Corp., Los Angeles, for research and development of a prototype quantity of pilot static tubes capable of withstanding exposure to temperatures up to 1400°C for 15 minutes to be used on aircraft and missiles flying at speeds up to Mach 5.

$44,929—Olin Mathieson Chemical Corp., Chemicals Div., Baltimore, for 7125 lbs. of monomethyl hydrazine for testing and evaluation in support of weapons system 138a.

$35,543—Curtiss Wright Corp., Electronics Div., Calstadt, N.J., for drone control and radar tracting systems simulator used in conjunction with a modified M-4 tracting radar.

$27,486—Ampex Corp., Newton, Mass., for recorder, reproducer, magnetic tape, seven channel.

$27,441—Kenick Manufacturing Co., L.I., N.Y., for rocket assembly used on F84 and F84F1 aircraft.

NASA

$500,000—The Siegler Corp., Hallamore Electronics Co. Div., for airborne computers and associated test equipment for the *Vega* outer space rocket (subcontract from Jet Propulsion Laboratory).

The civilian space agency awarded the following contracts during the month of May, in addition to those which appeared last week.

$110,000—National Science Foundation, for support of the Space Science Board of the National Academy of Sciences.

$60,000—University of Florida, for study of general instability of cylindrical shells, aimed at aiding both rocket and space vehicle designers.

$60,000—University of Wisconsin, for design studies of an ultraviolet telescope system to go into a future orbiting space observatory. The telescope would examine the radiation emitted by stars.

$50,000—Army Ordnance, for part of 20 *Nike-Asp* sounding rockets to be fired from Fort Churchill, Canada, and Wallops Space Flight Station in ionospheric sampling experiments.

reviews

CTR-371 COMPUTERS, 1937-58, Available from OTS, U.S. Department of Commerce, Washington 25, D.C.

A catalog of technical reports, listing all reports in the field of computers, has been published by the Office of Technical Services, U.S. Department of Commerce.

It identifies reports on digital, analog, photographic, mathematical, navigational computers and others. Many of the reports resulted from research conducted for the Army, Navy, Air Force, Atomic Energy Commission, and other agencies of the U.S. Government. Others are German documents captured during World War II.

METAL-CERAMIC LAMINATES, R. K. Francis, R. Brown, E. P. McNamara and J. R. Tinklepaugh, Alfred University for WADC. 78 pp, available from OST, U.S. Department of Commerce, Washington 25, D.C.

Using brazing and hot-pressing techniques, metal-ceramic laminates can be fabricated when the thermal expansion of the ceramic is equal to or slightly less than that of the metal. Fosterite-stainless steel 430, molybdenum-alumina, and Kovar-alumina liminates were fabricated by brazing techniques; laminates of molybdenum and a 40% alumina-60% mullite ceramic were hot pressed.

Thermal expansion and thermal conductivity studies demonstrated that mixtures of mullite and alumina can be used to provide a varying range of thermal expansion. Measured conductivities of the stainless steel laminates were much higher than calculated results. A comparative apparatus for measuring thermal conductivity was constructed and found accurate to plus or minus two per cent in the temperature range 100 to 1000°C.

YOU'RE ON THE INSIDE...

You make your point before the conference begins when you advertise in Armed Forces Management. It's the *only* magazine offering across the board coverage of *all* the military services in the $45 Billion Market. Armed Forces Management reaches 17,000 military and civilian executives in administrative, executive, procurement and evaluation positions. And you reach the *right* man in the *right* spot. AFM is addressed to job titles, not names, (majors through 5-star generals/admirals and civilian executives with Civil Service rating of GS-13 or above). This enables you to sell military purchasing influences month after month regardless of personnel rotation. *For a complimentary copy of the detailed Armed Services Marketing Manual, write Marketing Director, Armed Forces Management.*

propulsion engineering

You must be a defense contractor . . .
to use the new rubber and asbestos insulation that **Astrodyne** has developed for solid propellant motors. The company developed the insulation primarily for Navy use. It greatly extends the motor life and, in effect, adds to burning time. It's cheaper and lighter than reinforced plastics now in wide use. Typical test result: Insulation held exterior of motor case to 200°F for 3.5 min., under propellant flame of 5500°F.

Tantalum producers are skeptical . . .
about the drastic price cut made by **Union Carbide Metals,** according to the magazine *Chemical Week*. Carbide cut the tantalum price from $60/lb. down to $35/lb. early this month. There was a lot of talk about a new future for the metal—wider experimentation and development would now be possible. However, *Chemical Week* says Carbide's competitors are commenting that "Carbide has been selling close to the $35/lb. level for some time." Carbide replies, according to the magazine, that the higher price always was considered a "list price" subject to negotiation on large orders, frequently whittled down to near $35, where small orders have gone at near the $60 price.

Nuclear propulsion is a step closer . . .
to reality for aircraft, manned satellites and space ships, thanks to **Goodyear's** castable nuclear shielding material announced at mid-month. The synthetic rubber-powdered boron material shields crew members from neutrons. It features a new rubber molecule high in hydrogen content, as well as mixed-in boron. The hydrogen slows down the neutrons, the boron captures them.

Until now, polyethylene slabs have been used for lightweight shielding. However, the slabs are difficult to work with since they are too rigid to conform to many shapes. The Goodyear product is fully castable—pour it into any shape, it fills the entire volume and sets at about room temperature. Goodyear scientists believe the shield is the lightest and most effective neutron shielding material yet developed.

In spite of its high hydrogen content, the material can withstand temperatures from −60°F to 200°F. It absorbs radiation without damage. Goodyear says it's "reasonably priced."

Note: The material is not the full answer to missile and aircraft nuclear shielding problems. Lead still must be used to shield against gamma radiation. The Goodyear material, however, replaces the concrete and water neutron shields used in earth-bound installations.

Forced draft air heater . . .
for testing missile components at **Wyle Laboratories,** Norco, Calif., delivers 20 million BTU/hr. at 1500°F. The unit, built by **Hirt Combustion Engineers,** can deliver extremely high flows of gaseous oxygen or nitrogen, 35 lbs/sec at 200 psi. Purpose: Test missile components at actual operating temperatures and flows. This is one of the largest units of its type ever built, according to the builders, who say there is no practical limit to the size of future units.

High temperature reactions . . .
are studied by a new technique developed at **Bell Telephone Laboratories.** In describing the general technique in *Chemical & Engineering News*, Bell Telephone's Lloyd Nelson says it "may be helpful in attacking such problems as . . . prolonging the life of a missile nose cone, or developing protective clothing against nuclear blasts." Here's a capsule description: Fine particles or filaments of absorbing materials are suspended in a transparent medium and exposed to a high-speed, high-intensity flash of light. The particles hit a very high temperature and then cool again almost instantaneously. Chief advantage: The speed of the reaction does not allow time for side reactions —researchers can follow the main reaction without interference.

TELEMETRY

Boeing's expanding work on Minuteman, the Air Force's solid-propellant ICBM and other extremely advanced weapon system programs, has created exceptionally rewarding, long-range openings in the field of telemetry techniques, systems, sub-systems and equipment.

These are challenging opportunities for years-ahead work in the design, testing and evaluation of telemetry systems and components, as well as the development of new applications and techniques in areas such as:

- **Test Equipment**
- **Specialized Transistors and Signal Conditioners**
- **Pulse Code Modulation, Pulse Duration Modulation and FM/FM**
- **Missile Telemetry**
- **Flight Test Data**
- **Special Circuitry and Equipment**

Assignments are available at virtually all experience levels, and with educational backgrounds ranging from B.S. to post-Ph.D. At Boeing you'll be with an industry leader in the development of advanced weapon systems.

Drop a note *today*, to:

soviet affairs . . .

By DR. ALBERT PARRY

An alloy of iridium and aluminum . . .

as a tremendous boon to rocketry is discussed in the Moscow *Yunyi Tekhnik*. For a long time, despite all the experiments which were attempted, such an alloy could not be achieved, the Soviet magazine says. The reason for continued failure was plain: Aluminum melts at 660°C, while the melting point of iridium 2400°C.

But a new method . . .

accomplishing the needed alloy was at last found. The Russian journal calls the discovery "the meteorite-metallurgical technique." This consists of "shooting" at melted aluminum a charge of extraordinarily tiny particles of iridium emerging at a tremendous speed from a special electrical instrument.

"Not being in a molten state," the description in *Yunyi Tekhnik* continues, "iridium nonetheless fuses with the molten aluminum into an alloy. This alloy possesses the light weight of aluminum and the high mechanical and heat-resisting solidity of iridium, thanks to which it becomes an ideal material for the making of most important parts of airplanes and rockets." But to what extent this method and the resulting alloy are now being used in the Soviet Union, the Russian item does not say.

On broader implications . . .

of this subject, "Heat-Resisting Alloys" is the title of a special lengthy article in *Sovetskaya Aviatsia* by Professor N. Skliarov. He discusses the arrangements now being made by the Soviet government to expand and improve Russia's production of heat-resisting alloys in the Seven-Year Plan just begun (1959-65). Rather dismissing aluminum, magnesium, and other low heat-resisters, Professor Skliarov suggests that Soviet experimenters are now paying close attention to such "more infusible metals" as chrome, niobium, tantalum—and "the highest-melting metal—wolfram."

Yet Professor Skliarov also speaks of "extraordinary difficulties" hampering "the utilization of these metals." The *Sovetskaya Aviatsia* writer, who holds the degree of doctor of the technical sciences, says that these metals can be cast only in a vacuum, "in special arc furnaces from which air is barred." He reveals that the Seven-Year Plan is emphasizing the introduction and improvement of the arc-furnace method of casting various metals needed in aviation and rocketry.

Powder metallurgy is another field . . .

looming large in the Seven-Year Plan, according to Doctor Skliarov. "High heat-resisting materials," he writes, "can be obtained not alone as cast metal alloys but also by pressing and baking ready-made parts from mixtures of powdered metals with highly infusible compounds which melt at 3000°C and at yet higher temperatures."

The value of powder metallurgy, he continues, is in the fact that methods of this metallurgy help in the manufacture of such synthetic materials as "combinations of metals with their infusible oxides." He gives this example: The oxide of aluminum melts at 2500°C, and this oxide permits experimenters to create a material twice as heat-resisting as can be had from ordinary aluminum alloys.

Powdered or pulverulent metals . . .

can aid in the making of porous materials. The latter, as Doctor Skliarov points out, "combine solidity with their heat-resistance thanks to their cooling by a liquid flowing through the pores." The result is that experimenters obtain "most divergent combinations of materials with good heat-insulating qualities, a high thermal capacity, and the ability to absorb a great quantity of heat coming from outside."

That is why the Seven-Year Plan devotes so much attention to this part of Soviet technology and industry. Playing a significant role in today's technology, the heat-resisting materials "will have a yet greater importance in the technology of the future," the Soviet scientist concludes.

Memo from the Assistant Publisher

This is the first in a series of memos to you, the reader, keeping you informed about what we're doing and planning here at Missiles and Rockets.

Just as a starter, let's take a look at M/R's title, "The Magazine of World Astronautics." There are variations . . . such as "Technical/News Weekly of the Missile/Space Industry" . . . more comprehensive, but somewhat awkward. We believe our present definition, concise and to the point, is adequate.

Then consider the market. There are many industries combining to make up this Missile/Space field we talk about. Which are these industries, and who is the man . . . the engineer . . . whose efforts produce new developments in this area?

In short . . . for whom, and for what reason, is Missiles and Rockets being edited and published?

Astronautics Engineering (or missile engineering, space technology . . . call it what you will) has been defined as the applied science whereby simultaneous extensions of the state of the art in aeronautical, electronics, chemical, metallurgical and astrophysical engineering combine to produce new developments in the field of missiles and space vehicles. Each of these industries plays an integral part in the fulfillment of man's greatest venture to date: the perfection of the art of missilery and the subsequent conquest of space.

The astronautics or missile engineer may be basically an aeronautical engineer; he may be an electronics or chemical engineer, a physicist or metallurgist (if he's young enough, he may even bear the *title* of missile engineer). But to his basic knowledge in one or more of the above sciences he's had to add capabilities in magnetohydrodynamics, space communications, digital computer logic design, celestial mechanics, reentry simulation . . . there are scores of others.

To serve this man, the astronautics engineer, his proper diet of news and technical editorial coverage of all of these sciences *as they apply to missile/space projects* . . . coverage of Astronautics Engineering . . . is the editorial purpose of Missiles and Rockets and M/R's "reason for being."

Working toward more complete fulfillment of this editorial mission, M/R has made a number of changes and improvements in its editorial product over the past several months, not the least of which has been a decided increase in the amount and caliber of technical coverage. This week there are several more changes:

Missile Electronics, a familiar M/R department since the section was first instituted in October, 1957, now becomes Astrionics, a column heading we've used from time to time for several years. As the science of Astronautics Engineering broadens, so does M/R, and the term Missile Electronics is no longer broad enough in scope to cover electronics in both missiles and space systems. Hence a new title: Astrionics.

M/R's weekly Contract Awards feature, which you tell us is an invaluable information guide, has been expanded and relocated, enabling M/R editors to include the latest available award informati each week.

In keeping with our definition of Astronauti Engineering, we invite your attention to the editori masthead on page four, revamped this week. Nar the primary fields of Astronautics Engineering: stru tures, electronics, propulsion, materials, astrophysic support equipment, and you'll find an M/R edit (sometimes two) covering each.

To get more late news into M/R each wee the editorial by Executive Editor Clarke Newlc will be moved back to this page beginning ne week; you'll find it here from then on.

So far this year, M/R has published 955 pag of editorial material devoted to the Missile/Spa market . . . more than any other magazine of a type. Beginning on page 37 of this issue, you'll fi an editorial index for the period January throu June 1959.

In addition to thorough weekly news coverage Astronautics happenings in Washington and arou the world, we've inaugurated a program to give reade a minimum of four "round-up" or "state-of-the-ar articles each week, letting you know where we've bee "where we're at," and where we're going in technic areas vital to Astronautics progresses.

Take, for example, the "Fuzing and Arming" sto on page 30. Here Astrionics Editor Hal Gettings e plores a technology of extremely high reliability paran eters, and identifies industrial and government leade in the field.

Beginning this week on page 13 is the first in three-part series by Associate Editor William E. Howa on the Missile Industry in New England . . . an ar which garners over $1 billion each year in missile co tracts and employs more than 150,000 people. Ne week Bill will get more specific and survey the Bosto area; on July 27th: a Connecticut close-up. Surveys other U.S. missile manufacturing areas will follow.

What's the outlook for aluminum? Cryogenics? A sociate Editors Paul Means and Frank McGuire te these stories on pages 18 and 21 . . . stories compile after hundreds of miles of travel on both East and We Coasts, and hundreds of man hours of editorial r search. More of this type of editorial treatment w follow next week when M/R editors discuss printe circuitry, monopropellants and the vehicle requiremen for Missile Support.

On July 20 you'll see M/R's Third Annual Enginee ing Progress Issue, featuring the famous Guided Missi Encyclopedia, expanded this year to include the late available information on British, French, Swiss ar Italian missiles in addition to those of the United Stat and Russia. Watch for this issue: It will be M/R's bi gest weekly effort to date.

Keep us posted on how we're doing: keep yo criticisms and suggestions coming. M/R is being edite for you . . . the Reader.

E. D. Muhlfeld
Assistant Publisher

PRECISION GYROS

A Proven Kearfott Capability. The increasing use of Kearfott gyros and gyro platforms in today's missile programs, underscores the company's leadership in gyro design and production. Such missile projects as the Atlas, Bomarc, Polaris, Snark, Subroc and Talos rely on Kearfott gyros or gyro platforms, as do the majority of manned aircraft now in service.

FLOATED RATE INTEGRATING GYROS. High accuracy miniature gyros specifically designed for missile use. The performance characteristics of these gyros are superior to any comparably-sized units available today. Hermetically sealed within a thermal jacket and ruggedly designed for adaptability to production methods. These gyros operate efficiently at unlimited altitudes. More precise performance characteristics can be provided in the same dimensions.

TYPICAL CHARACTERISTICS

Mass Unbalance:
Along Input Axis: 1.0°/hr maximum untrimmed
Standard Deviation (short term):
Azimuth Position: 0.05°/hr
Vertical Position: 0.03°/hr
Drift Rate Due to
Anisoelasticity: Steady Acceleration: .015°/hr./g² maximum
Vibratory Acceleration: .008°/hr./g² maximum

Damping:
Ratio of input angle to output angle is 0.2
Characteristic Time.
.0035 seconds or less.
Weight: 0.7 lbs.
Warm-up Time:
10 minutes from—60°F
Life:
1000 hours minimum

VERTICAL GYROS. Provide accurate vertical reference in the form of two 400 cps synchro signals proportional to the sine of gimbals' displacement about pitch and roll axes. Gravity-sensitive vertical reference device provides electrical signals directly to torque motors which maintain gyro spin axis perpendicular to earth's surface. Hermetically sealed, they are unaffected by sand, dust, sun, rain, salt spray, humidity or fungus conditions as specified in MIL-E-5272A.

TYPICAL CHARACTERISTICS

Repeatability to Established Vertical: To within a cone of half angle equal to 15 minutes of arc (± 8 minutes typical).
Free Drift Rate in 5 minutes Time: 2.5° maximum at room temperature. 3.75° at −54°C and + 71°C.
Erection Rate: 2.5°/Min.
Initial Erection: The gyro will erect to within ± 1° of established vertical in 60 seconds time after application of power at room temperature.
Vibration and Shock: The gyro will meet above characteristics after vibration of 0.060" total excursion cycling between 10 CPS and 55 CPS for 4.5 hours. Shock test in accordance with MIL-E-5272A Procedure 2.
Operating Life: 1000 hours minimum.

FREE GYROS. Provide extremely accurate reference in the form of electrical output signals proportional to displacements about outer axes. With 360° of freedom about outer axes (inner axis freedom depends on the unit involved), these gyros may be mounted to give output signals of either pitch, roll or yaw. Shock and vibration resistant, they are equipped with quick-starting motors for applications in high performance missiles and aircraft.

TYPICAL CHARACTERISTICS

Free Drift Rate: Within 0.5° in one minute time.
Shock: The gyro operates satisfactorily without damage after 60g shock of .015 seconds duration.
Hermetically Sealed: These instruments are hermetically sealed and are not affected by sand, dust, sunshine, rain, humidity or fungus conditions.
Operating Temperature Range: Gyros operate in ambient temperatures below −20°C to + 100°C. A maximum of 3 minutes of operation at 400°F will not damage these gyros nor impair their accuracy.
Weight: 5.5 lbs. approximately.

SPRING RESTRAINED RATE GYROS. Almost universally applicable in missile and aircraft designs demanding precise angular rate measurements in environments of extreme shock and vibration. Fluid filling provides added immunity to shock and vibration, reduces bearing friction in AC types and potentiometer wiper friction in DC types. Kearfott design advances permit 30 second warm-up, overcome fluid viscosity variations resulting from ambient temperature change. These gyros are single-degree-of-freedom, viscous damped, spring restrained, with gimbals supported by precision bearings. Compensatory damping mechanisms eliminate need for accessory heaters.

TYPICAL CHARACTERISTICS

Maximum Rate (°/sec.): 45-1000
Natural Undamped Frequency (cps) (± 10%). 16
Damping Ratio (of critical) over Temperature Range: .35 to .80
Operating Temperature Range (°F): −65 to +185
Vibration: 12 g's @ 20-2,000 cps
Shock (Motor Running): 60 g's for 6.5 milliseconds

Warmup Time (Sec.):	30
Weight (lbs.) (max):	1.5
Gyro Time Constant (Sec.):	.012

Engineers: Kearfott offers challenging opportunities in advanced component and system development

...NEWS IS HAPPENING AT NORTHROP

Demonstrating the platform of LINS – new, Lightweight Inertial Navigation System – is Dr. William F. Ballhaus, Vice President and General Manager of Nortronics.

NORTRONICS REVEALS LINS... COMPLETE PRECISION INERTIAL NAVIGATION SYSTEM!

A recent demonstration at Nortronics' Guidance Symposium revealed the most advanced precision inertial guidance system ever assembled. LINS – Lightweight Inertial Navigation System – includes platform, platform electronics, environmental control and computer. Total system weight: slightly in excess of 100 pounds. Equipment volume: less than three cubic feet.

Actual working hardware, LINS is a complete, precision system for automatic navigation applications to advanced aircraft, drones, missiles, and space vehicles. It is ready now – the latest result of Nortronics' more than twelve years of creative research and production in the field of automatic guidance and navigation systems.

If you have the need to know more – contact Nortronics today, regarding LINS for your own system requirement. Nortronics' experience offers unique and proven capabilities in tailoring the design, development and production of complete and integrated guidance systems to your requirements.

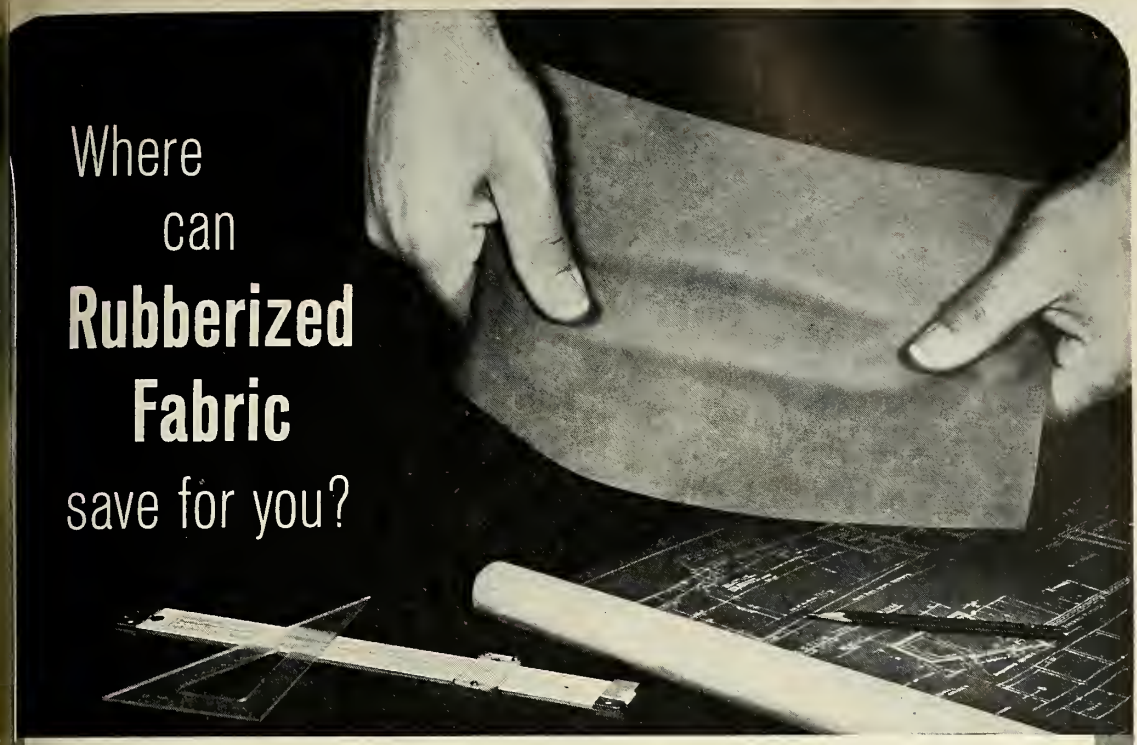
STEPS IN THE RACE TO OUTER SPACE

Nuclear Rocketship

Despite the sky-high transportation costs, Lunar manufacturing should prove economically viable. With unlimited Solar power, controlled atmospheres and advanced automation, a considerable commerce could be realized in delicate instruments, rare minerals, reactor cores and other items that might be more efficiently processed or produced in the Moon's perfect vacuum.



To supply the Moon colonists, and to carry their production back to Earth, special rocketships will be developed. Nuclear energy is the most promising source of propellant power. The ship shown here utilizes nuclear fission for heat and hydrogen gas as a working fuel. From pressurized tanks, the gas is fed through a heat exchanger, expanded, and expelled for the motive thrust.

When the craft leaves Earth, it carries only enough gas for a one-way trip. For, by extracting hydrogen and oxygen from Lunar rocks, Moon settlers will be able to refuel the rocketship for the return age. This will permit smaller fuel ta on the craft and larger payloads.

Inertial navigation systems will pla increasing role in the exploration of o space. ***ARMA***, now providing such tems for the Air Force ATLAS ICBM, be in the vanguard of the race to o space. ***ARMA*** . . . Garden City, N A Division of American Bosch Arma C

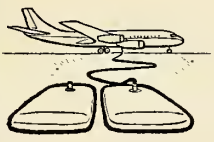
Where can **Rubberized Fabric** save for you?

Need strength, flexibility and portability in one lightweight material? Goodyear Rubberized Fabric may be your answer.

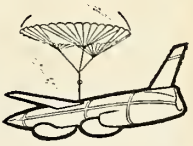
INFLATABLE, PORTABLE

Air Mat Fabric provides excellent insulation against heat, cold, vibration. Ideal for personnel shelters, portable scaffolding, shock cushioning. Beams made of this unique rubber-coated inflatable material have highest strength-to-weight ratio known.



INFLATOPLANE

—another ingenious application of Air Mat Fabric. Pilot simply unfolds it, inflates it—and *flies away!* Do your plans call for a lightweight structural material that can be moved easily, occupies a bare minimum of storage space, can be erected quickly?

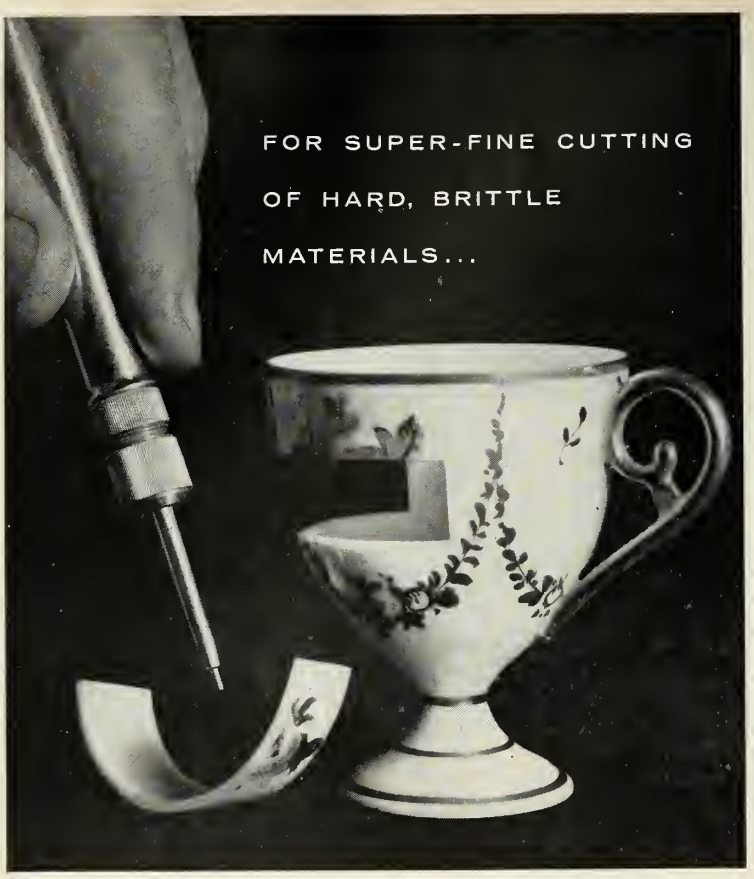


LOOK! COLLAPSIBLE FUEL TANKS

that unroll like a rug—can be set up, filled and pumping 45 minutes after delivery. Eliminates need for bulky, hard-to-handle metal drums. Designed for use wherever temporary or emergency storage of gasoline, oil, water—any bulk liquid—is required.

WANT TO BRING A MISSILE BACK?

Goodyear Recovery Bags—made of tough, rubberized fabric—fold into test missiles, inflate on way down to cushion ground impact. Saves the missile for firing another day, eliminates cost and weight of electronically operated conventional landing gear.



FOR DETAILED INFORMATION on rubberized fabric—and how it can save for you—write Goodyear, Aviation Products Division, Akron 16, Ohio, or Los Angeles 54, California.

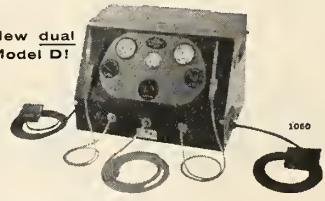
RE AIRCRAFT LAND ON GOODYEAR TIRES, WHEELS AND BRAKES THAN ON ANY OTHER KIND

THE S.S.White Industrial Airbrasive Unit

We don't recommend slicing up the family's fine Limoge China, but this does illustrate the precisely controlled cutting action of the S. S. White Airbrasive Unit. Note how clean the edge is, and how the delicate ceramic decoration is unharmed.

The secret of the Airbrasive is an accurate stream of non-toxic abrasive, gas-propelled through a small, easy-to-use nozzle. The result is a completely *cool* and *shockless* cutting or abrading of even the most fragile hard materials.



Airbrasive has amazing flexibility of operation in the lab or on an automated production line. Use the same tool to frost a large area *or* to make a cut as fine as .008"!...printed circuits...shaping and drilling of germanium and other crystals...deburring fine needles...cleaning off oxide coatings...wire-stripping potentiometers...engraving glass, minerals, ceramics. Jobs that were previously thought impossible are now being done.

Send us samples and specs on your difficult jobs and let us test them for you.

SEND FOR BULLETIN 5705A . . . complete information.

Zippered nose cone cover foils moisture, dust, abrasion

To protect the polished finish of missile nose cones from assembly to countdown, B. F. Goodrich fabricated unique zippered "all-weather" Nose Cone Covers for Avco's Research and Advanced Development Division.

Made from neoprene coated nylon fabric, this shipping cover has non-rigid neoprene ribs and spacers that keep it from riding down on the cone. Special B. F. Goodrich Pressure Sealing Zippers provide easy access and removal—yet seal positively against dust, dirt, grime, damaging impact.

B. F. Goodrich was asked to engineer this special project because of its widely-known ability to manufacture coated fabrics to any shape or size—as in aircraft baggage pa In addition, the space-saving B. F. Goodrich Zipper—u widely for air ducts, inspection ports, access doors, and aile gap seals—withstands any pressure up to the maxim strength of the zipper itself. And it, too, can be fitte complex contours.

Tricky sealing problems like this one are just part of day's work at B. F. Goodrich. Next time you have suc problem and need an answer—fast—write or call *B.F.Good Aviation Products, a division of The B.F.Goodrich Comp Dept. MR-79, Akron, Ohio.*

Washington Countdown

IN THE PENTAGON

A Lockheed *Polaris* . . .

is expected to be launched from a surface ship sometime within the next six weeks. The launching from a tube aboard the *Polaris* Test Ship Observation Island in the Atlantic probably will be preceded by the launching of a *Polaris* from a sea motion simulator at Cape Canaveral.

• • •

Meantime, wider use for *Polaris* . . .

is being stressed by Navy officials—apparently with an eye to hit at AF proposals to incorporate the *Polaris* system in SAC. Navy officials note *Polaris* subs will be able to perform patrol and ASW jobs while on station. Also, they plan to be able to launch *Polarises* from surface ships such as the new nuclear-powered cruiser Long Beach.

• • •

Two new Army missiles . . .

Davy Crockett and Convair's *Red Eye,* are reported being sought by the British Army. Both are light nuclear-warhead hurling weapons designed for the use of troops in the field.

• • •

A top-level Air Force committee . . .

is studying ways to tighten up the weapon system concept of management. The committee is particularly looking for ways to improve programming and possibly slow down the rotation of project officers.

• • •

Curtailment of operations . . .

at the sizable U.S. missile tracking base on Fernando Noronha Island off Brazil is reported to be in the works. Reason: Not enough data collected to justify the high cost.

• • •

Pentagon R&E Director Herbert York...

is trying to avoid some of the inter-service knife play that helped undercut onetime Missile Czar William Holaday. The ex-czar had only one military adviser representing all three services. York has appointed one military adviser from each service.

ON CAPITOL HILL

A major public airing . . .

of repeated delays in the nuclear-powered aircraft program is the goal of the Joint Atomic Energy Research Subcommittee's forthcoming hearings. The two-day open hearings—first on the ANP program since it began more than a decade ago—are expected to start about July 22. Subcommittee members are expected to charge the Administration with setting back three years the development of a nuclear-powered aircraft—a potential principal carrier of ALBM's.

• • •

The Hébert Subcommittee . . .

has called in a team of experts to compile results of its questionnaire poll of retired military and Federal civilian officials employed by defense contractors. Results are expected to begin to show up when the subcommittee calls in a parade of ex-military brass later this month.

• • •

The Martin *Mace-B* . . .

is now expected to survive the congressional ax after all. Language in the Senate version of the defense appropriations bill would permit the Air Force to get new funds for *Mace* under a general money transfer clause permitting the switching of money from other projects. The House probably will go along.

AT NASA

***Little* Joe, the poor man's *Atlas* . . .**

will be tested later this month at NASA's Wallops Island Test Center. *Little Joe,* which costs a sixth as much as an *Atlas,* is a cluster of six solid-propellant rockets capable of boosting a Project *Mercury* man-in-space capsule to a speed of about 4000-miles an hour for testing escape equipment.

AROUND TOWN

Some of the reports . . .

that are being passed as the "latest" in the nation's capital:

. . . Congressional Democrats are feeling the pinch of Democratic Advisory Committee demands for billions more for defense.

. . . The French are planning to build a huge missile range—probably in French West Africa.

. . . Some top Pentagon officers are warning that development of manned space vehicles is a life-or-death race with Russia.

A UNIQUE APPROACH TO INFRARED GUIDANCE

This precision spherometer measures a unique material developed at Hughes for infrared guidance. It can measure the curvature of the dome's surface to an accuracy of 10^{-6} meters.

The material tested is unique in that it is completely opaque in the visible region, yet transmits very well in the infrared. First application of this material to military equipment requirements was carried out at Hughes.

This project is just one of the advanced studies in all phases of radar, inertial and infrared guidance currently underway at Hughes Research & Development Laboratories.

Assignments in missile guidance now open include:

Physicists to conduct Radiation Detector Studies
E.E.'s for Experimental Circuit Design
E.E.'s for IR Systems Studies
E.E.'s for Servo Analysis and Simulation
Optical Designers

The salary structure for the above positions reflects the advan nature of the assignments. Please inquire by writing directly Dr. Allen Puckett, Assoc. Director, Hughes Systems Deve ment Laboratories.

the West's leader in advanced electronics **HUGHES** *Hughes Aircraft Company, Culver City 54, California*

Industry Countdown

All signs continue to point . . .
to **Boeing** as winner of the *Dyna-Soar* contract despite Air Force decision to delay making award. Indications are that the "further studies of various aspects of the program" announced by Air Force involve strong political pressure for greater spreading out of the big money package—particularly to firms that have suffered cutbacks in other programs.

STRUCTURES

France is cutting off . . .
production of **Sud Aviation** *4200* and *4500* ground-to-ground missiles and concentrating on development of a ground-to-ground ballistic missile. Work will be done at Sud's Cannes plant. Sud also is researching a strategic ballistic missile to be developed by SEREB.

• • •

Raytheon *Hawks* . . .
will be in large-scale production shortly. Assembly of the Army's operational anti-aircraft missile will begin late in the summer at the Red River Arsenal, Texarkana, where major components will be shipped from all over the nation. Guidance packages will come from **Raytheon's** Andover, Mass., plant; solid-fueled motors from **Aerojet-General's** Sacramento facility; frames from **Northrop Aircraft,** Anaheim; warhead from Iowa Ordnance Depot; and missile shipping containers from the **Williamson Co.,** Madison, Ind.

• • •

Production of advanced *Terriers* . . .
is under way at the **Convair**-operated Naval Industrial Reserve Ordnance Plant at Pomona, Calif. The new solid two-stage *Terriers* will be a major weapon in the Navy's missile arsenal. The new guided missile frigate Dewey will get it first.

• • •

Air Force now setting up . . .
precision calibration laboratories at many of its bases. About $6 million has been allocated for equipment and contracts have been let. Aim is for 168 of the labs ultimately. They will be utilized chiefly for maintaining accuracy of measurement for extremely close-tolerance missile components.

Under $2 million AF contract . . .
Lockheed Aircraft will build four 1400-mph F-104 jet fighters as missile target drones.

• • •

Navy interest in explosive forming . . .
of refractory metals is increasing. BuAer has awarded **Chromalloy Corp.** substantial contract to develop new techniques and practices in producing complicated shapes.

ELECTRONICS

Missile site survey unit . . .
is being formed by the Air Force at Orlando AFB to establish exact location of ICBM, IRBM and space vehicle launching. Data will be used to increase accuracy of plotting trajectories—and aid in predicting missile impact.

• • •

Funding for *Midas* and *Sentry* . . .
in Fiscal 1960 is now set. AF is putting $19.1 million into *Midas* ballistic missile early warning satellite and $4.45 million into *Sentry* recon satellite. *Midas* facilities are to be situated in remote area of the United Kingdom. **Convair** *Atlas* boosters will be used to put both systems in orbit.

PROPULSION

Avco Lycoming Division has won . . .
$6 million **Aerojet-General** contract to make second and third stage *Minuteman* motor chambers, and chambers for *Polaris.*

• • •

Theoretical studies . . .
of propellant sloshing and dynamic propellant tank deformation is part of a $1 million research assignment handed the Army Ordnance Missile Command by NASA. AOMC also will investigate celestial mechanics of missile and space vehicle trajectories and ablation effects.

• • •

More monopropellant research . . .
will be undertaken by **Stauffer Chemical.** Navy contract for $100,000 is third awarded the company by the services in high-energy field.

SPACE MEDICINE

Two-man space cabin simulator . . .
will be delivered in October to the new $10 million Air Force School of Aviation Medicine at Brooks AFB, San Antonio. School personnel are now in process of moving from old quarters across town at Randolph AFB.

AIRBORNE...NEW USAF T-38 TALON!

The T-38 Talon fills a vital requirement of the Air Training Command. It is a lightweight, low-cost aircraft in which our new generation of space age airmen can safely master the art of supersonic flight.

Pioneering a new Northrop family of economical manned aircraft for the space age, the Talon is a direct result of teamwork between Norair and suppliers. This T-38 Team that made the trainer a reality is now producing it under USAF contract at Hawthorne, California. Soon to follow is the N-156F multi-purpose fighter, American-designed for our free-world allies.

The T-38 Talon stands as the latest airborne evidence of Norair capability and production know-how. Norair's creative management further adds to the accomplishment by trimming production costs with methods that include PACE — the unique Performance And Cost Evaluation program; new and superior quality controls; and Norair-conceived, years-ahead production techniques.

NASA Braces To Fight Cuts

by Paul Means

VASHINGTON—Two Russian dogs ed Snowflake and Daring, and an med Russian rabbit could be A's best bet to rejuvenate Con-'s flagging interest in space re-ch.

The latest Soviet space experi- came after the House lopped 68 million from NASA's supple-al FY '59 and FY '60 budgets, just before the Senate began its erations.

Congress leaped into action after Russians orbited *Sputnik 1* in ber of 1957, claiming that the inistration had been stingy with e research money. NASA hopes the latest Russian experiment will arly shake Congress out of its ent lethargy.

• **What could happen**—If the space cy *has* to make do with $68 mil-less, it may mean that the whole A schedule for space research, in-ng Project *Mercury's* attempt to the first man in space, will have e revised.

Schedules for the big space boost-such as *Vega, Centaur, Nova,* and *rn,* will have to be lengthened so they do not run out of money. firings of *Vega,* expected in late), may have to be delayed.

he cut will also mean less space re-h, without the insurance in some of back-up shots in case the experiment fails.

• **One-two punch** — The House's t-face on money for space re-h culminated last week when the e Appropriations Committee d to cut the NASA budgets by 500,000. Committee member Rep. rt Thomas (D-Tex.) defended the by stating that NASA had more ey than it could spend wisely.

dding to space agency's woes was chnical point of order raised by H. R. Gross (R-Ia.) which elimi-d what was left of the $48,354,000 he NASA FY '59 supplemental. Gross pointed out that a recently d law forbids the House to appro-e money for NASA not "here-" authorized by the House Com-e on Sciences and Astronautics. Committee had authorized the lemental before the passage of the law (P. L. 8645) not "hereafter" as the language of the law requires.

The House then salvaged $18 million of Project *Mercury* R&D funds in the supplemental by tacking them onto FY '60 budget. Lost was $22,-725,000 for construction and equipment, bringing the total loss to the NASA budget to $68 million.

NASA officials are confident that the House space committee will either re-authorize the funds kicked out by Rep. Gross's technicality, or amend P. L. 8645 so that the words "hereafter" do not apply to their earlier authorization of this money.

• **The real danger**—What they are worried about is the $45,500,000 cut, which NASA Administrator Dr. Glennan warns will cripple efforts to establish U.S. leadership in space research.

NASA spokesmen point out that the $35,145,000 cut in R&D funding would severely cut into the funds available for the development of advanced systems, such as *Vega, Centaur, Nova,* and *Saturn.* They point out that $310 million of the $354 million NASA asked for in R&D money goes for fixed costs required to continue contractual obligations started in 1959, and to pay for operational costs of already ordered items.

To cut $35,145,000 out of the R&D budget—as the House has done—leaves NASA with only $8,305,500 for development of advanced systems. In order to re-balance the program, NASA scientists say they will have to delete scheduled space flights, slow down procurement of equipment for these flights, and delay important elements of the NASA flight program.

Such delays could have international repercussions as well as denying NASA scientists needed knowledge. The cut in Project *Mercury* R&D funds in the FY '59 supplemental by 10% will mean according to NASA spokesmen, a slowing down of the program, thereby jeopardizing the U.S.'s chance of being the first nation to place man in orbital space flight.

Other important programs, such as the meteorological and communications satellite programs, and nuclear engine research under Project *Rover,* may have to be delayed.

• **Tracking threatened** — Another cut NASA officials say the program cannot sustain is the $7,325,000 slash in the construction and equipment allocation. If the funds trimmed out by Rep. Gross's technicality are included, NASA's construction and equipment budget would be cut by $30,050,000.

Much of this money is needed for the Project *Mercury* tracking range, without which the astronauts cannot take their first ride into space. The importance of the new tracking facilities was underlined recently when NASA attempted to award the contract for construction and integration of the range by July 1.

The House cut also reduced the NASA proposed salaries and expenses budget by $3,030,000, which will deny the use of 100 new employees to the space agency. Many of the new NASA employees were to man the expanded worldwide tracking and observation installations.

• **Rock bottom**—NASA had pretty well wrung its budget dry before submitting it to Congress. In fact, some observers had felt that the NASA budget was too small, and that the space agency would have to ask for fore funds later in the year. (See M/R, April 20, page 24.) Dr. Glennan admitted as much in criticizing the House cut, stating that the Space Agency had learned that money for certain projects did not go as far as its had originally seemed it would.

NASA hopes for restorations of the House cuts rest first with the Senate Appropriations Committee, chairmanned by Sen. Carl Hayden (D-Ariz.) If the space agency gets by this hurdle, then action by the Senate as a whole and the Senate-House Conference will decide the budget's fate.

• **Friend in power**—A strong ally on the side of the space agency should be Senate Democratic Leader Lyndon Johnson of Texas, chairman of the Senate Aeronautical and Space Sciences Committee, which has already authorized the NASA budget in total, and an advocate of space research since the launching of *Sputnik 1.*

If the majority leader can swing the support of his party, then prospects are good that the NASA budget cuts will be restored. In the House, the Republicans in general favored the total NASA budget and the Democrats favored the cuts.

Boston—'Hub' of Space Research

Tracing the development of a proud city's leadership in many fields of the space race; a look at the famous 'Golden Semicircle'—second in a series of regional surveys

by William E. Howard

BOSTON—Few cities physically show the nation's explosive growth in missile/space manufacturing and research more than Boston—a culturally endowed community which long ago laid claim to being the "Hub of the Universe," and where industry today is in the process of making this extravagant boast come true.

The entire metropolitan area is rapidly emerging as the country's leading research center. Scientists in hundreds of laboratories are conceiving and putting together the sophisticated offensive and defensive weapons of tomorrow. And they are responsible for much of the brainwork going into astronautic systems which one day will enable man to explore space.

Nowhere is the magnitude of this fast-expanding activity more eye-arrestingly apparent than along a 65-mile stretch of superhighway skirting the city from north to south in a great arc. Down the length of this busy artery there already are more than 200 modern plants employing more than 30,000 persons.

This is Route 128—Boston's "Golden Industrial Semicircle." Less than 10 years ago, it did not exist. Route 128 was only a country road meandering through meadows and woods, and connecting suburbs.

Where there were pig farms only a few years ago, today "industrial parks" are springing up. Once-quiet towns are the scene of more development. Industrial brick and mortar investment alone is estimated at $140 million. The entire complex—including business and home development—is valued at more than $500 million, and the figure is increasing.

Land values have shot up from $1000 an acre to as much as $26,000—with plenty of takers. All segments of industry are represented in this booming new area. But electronics is far and away the most predominant.

• **Key to growth**—Originally, conversion of Route 128 into an expressway was conceived primarily as a way to divert traffic around Boston's congested streets. But by the time it was opened in 1951, developers were already making plans to attract new industry. Electronics manufacturers just beginning to open a vast new market were the first to see its advantages for locating efficient one-story plants—with the highway affording quick transportation and the historic old towns offering pleasant living.

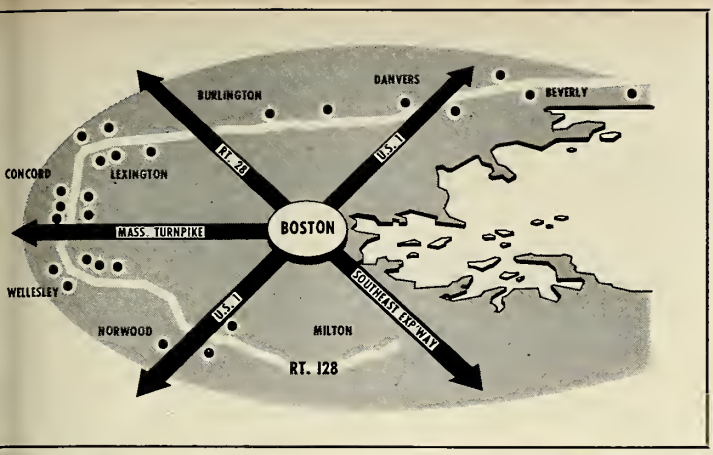
Gravitation to Route 128 was slow at first. Then research took over, mushrooming the growth of the electronics industry and forcing the construction of new plant facilities. Concurrently, in the early '50's, came the development of missiles with their heavy electronic requirements.

One after the other, **Raytheon Mfg. Co., CBS Electronics, Sylvania Electric, Avco** and other well-known companies moved out to the new highway.

Paving the way for the migration were such real estate developers as the Boston firms of Cabot, Cabot & Forbes and R. M. Bradley & Co. They were the ones that launched the industrial park plan, offering in one package a ready-prepared site, well-located, and engineering facilities to design any type of plant for purchase or lease. Both firms are credited with contributing greatly to the orderly development of Route 128.

Thirteen industrial parks are either completed or in final construction stages and three more are being started. These parks are absorbing, too ever-mounting number of new spawned in the dawning of the Age.

Illustrative of what is happeni the case of **Itek Corp.** Founded two years ago by four Boston U sity engineers, Itek now has more 700 employes engaged in classifie connaissance satellite and other work. In quick order it bought plant on 128, leased 65,000 squar of the **Waltham Watch Co.** works is planning to build a laboratory 43-acre site in Lexington near "Golden Semicircle." Incidentally also has a new West Coast install



Another spectacular examp **Transitron.** Founded six years ago eight employes, it now has 3000- is the second-largest semicond producer in the nation.

In the past two years more $52 million has been poured int plants along Route 128—and opers feel there is room to doub present total. Visibly supporting optimism, the fabulous expansion keeps on accelerating.

• **Air Force millions**—Perha biggest single contributor to the ing boom—not only along 128 elsewhere in the metropolitan ar the Cambridge Research Center Air Force's Air Research and De ment Command. CRC has beer still is funneling millions of dollar research.

As of May 31, CRC had out ing 1199 contracts totalling $32 lion. Millions more in contracts duction and research—are being p into the area by the AMC, N ARPA, the Army and Navy, an vate industry as well.

• **The MIT influence**—Han

OF the Boston area shows some of the towns where many missile/space plants sprung up. More than 30,000 persons are employed along Route 128 alone.

with CRC as a font of new ideas, ledge—and industrial talent—is Massachusetts Institute of Tech- y. Scores of firms owe their exist- to MIT, through its creation of productive fields of research and sion of brains to work them. arvard and other Greater Boston utions also are producing a con- us stream of technical talent. n September, the **Mitre Corp.,** a n-profit organization which takes ame from MIT, will move into million plant at Bedford along e 128. Mitre, under a contract MIT, serves as the technical staff ie Air Defense System Integration ion working on correlating activi- f human operators with the com- electronic gear of SAGE. litre, which has H. Rowan Gaither airman of its board, expects to d to a $5 million facility and ually employ 1500 to 2000. The presently is located in Lexington, ironically, the liberty of the na- vas once entirely in the hands of human operators. On the village green 77 Minute Men armed with muskets fired on the British in 1775 in the first conflict of the Revolutionary War.

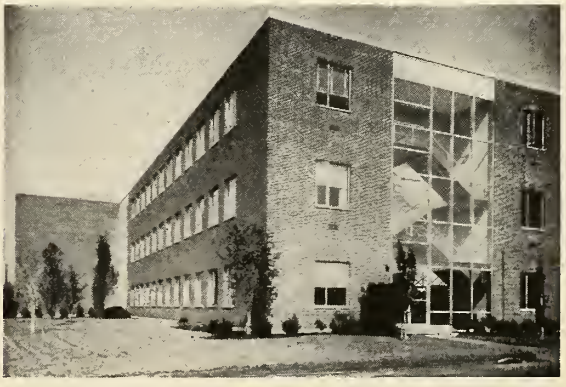
MIT made history at its Lincoln Laboratory along Route 128 by bouncing a signal off of Venus in February, 1958, when it was 28 million miles from earth, with a 90-ton radar telescope. It took a year to decipher the data, and the feat was disclosed only a few months ago.

From MIT's Instrumentation Laboratory, headed by Dr. Charles S. Draper, has come the all-inertial guidance system for *Titan*, which is being manufactured by **A. C. Spark Plug Division** of **General Motors,** and many more important contributions to the defense effort.

• **Within a decade**—Greater Boston Chamber of Commerce officials estimate there are more than 430 missile, electronics and nucleonics-connected industries—almost all founded within the past decade. These are scattered throughout the area. At last count, however, 63 were situated along Route 128.

One of the oldest research firms is the **Arthur D. Little Co.** of Cambridge, which among other items is deep in cryogenics and is preparing the design and specifications of MSE for fueling *Atlas* and *Titan*. **National Research Corp.,** also of Cambridge, has just come up with a new cryogenic storage vessel which has insulation improved by a factor of 15 over conventional devices.

At Waltham, **Infrared Industries** is producing missile guidance devices; at Lawrence, missile-carrying cases are being made by **Craig Systems;** and at Burlington, **Dynametrics Inc.** is hard at work on an Avco subcontract making measuring devices for *Titan* nose cones.



The activities of Greater Boston firms go into virtually every missile/space system, either as components or —as in the case of Raytheon, which has the prime contract for *Sparrow* and *Hawk*—the entire system.

The business scene shifts continually. **Bomac,** producer of Klystron tubes at Beverly, Mass., at the northern end of Route 128, recently merged with **Varian** of Palo Alto, Calif. **Texas Instruments** of Dallas has acquired **Metals & Controls Corp.** of Attleboro —the nation's first privately-owned nuclear fuel manufacturer.

Bostonians are looking to at least three firms to put them in the forefront of the space race. Avco at its new $23 million laboratory in Wilmington is working on interplanetary shockwave research and developing space systems. At the new **Goodrich-High Voltage Astronautics Inc.** in Burlington, work is being launched in development of ion propulsion engines. And at Raytheon engineers are working on a "sky station" which would hover miles above the earth in a fixed position—powered by microwaves beamed from the ground.

THAM Research & Development Park. Thirteen industrial are either finished or in final construction stages.

BUILDING AT the Arthur D. Little, Inc., West Cambridge Research Center, heavy in both cryogenics and major MSE.

First Things First— A Formula for Reliability

An expert decries our misplaced emphasis on perfecting assemblies and urges priority for materials

by John N. Dick
*(Colonel USAF, Ret.)**

WASHINGTON—A new word has made its way to the top of the vocabulary of modern weapon systems—the word RELIABILITY.

The concept of reliability as applied to military materiel is not new, of course, but with the coming of everyday missile firing and the approach of manned space travel, the word has assumed new importance. Contributing to awareness of the vital importance of component reliability have been:

• Serious and substantial failures of critical aircraft, rocket and missile missions, including some repeated failures of missiles considered to be operational.

• Recognition that the failure of one small and perhaps inexpensive part can abort a mission costing millions of dollars.

• The tremendously high costs of modern systems and equipment, including both astronomical initial cost and continuing high costs of maintenance.

Recognition of the necessity for reliability goes beyond the military, of course. Intense national interest has developed as a result of some spectacular and highly publicized missile failures, and as a natural by-product of the international race in space travel. As a result of this interest, accompanied by some concern and doubt as to our scientific and production capabilities, Congress has looked into these areas.

As their awareness of the critical nature of component reliability has grown, military materials suppliers have come to recognize reliability as a functional responsibility of organization.

Although reliability problems have been better defined and some praiseworthy efforts made to solve them, on the whole these efforts have been too sophisticated for complete success. The basic flaw is that the primary effort to insure reliability is applied at the wrong end of the complex weapon system program. Too much engineering time and attention have been devoted to perfecting an assembly of complicated components, and not enough to perfecting individual parts and—even more important—the basic materials themselves.

How effective is it to require 100% testing of component parts for reliability without fully appreciating and perfecting the specifications of the basic materials from which they are produced?

• **Misplaced emphasis**—Because of the knowledge, ability and experience of topflight aeronautical designers, the emphasis in missile design has been on sophisticated performance of very complex systems; not enough attention has been given to development of materials capable of such performance. A by-product of this misplaced emphasis is that much research and development effort is expended not in the laboratory but on the shop or factory floor—the least efficient and most expensive place for research and development.

Despite the excellent technical advice and assistance which commercial suppliers can provide the military in areas of metals, ceramics, chemicals and other materials and services, the systems designer and operator often have the impression that they must work only with whatever materials are in being. Except in the laboratories of some progressive suppliers, the concept of vigorous and thorough basic R&D of new materials, designed for spe and exacting performance requireme is not well-established. The resul "fire-fighting" system of stamping weaknesses and "crash programs" rected at troublesome areas boost terials costs and subtract from overall quality which could be obta with available funds.

If a broad solution to the prob is to be found, policy thinking al defense will have to be re-orier Basic research will be required to a better perspective on the system the future.

• **Present and future**—Immec solutions to the practical problem reliability will demand more atten (and surely more funds) for:

• More thorough study of the terials now in use in systems and c ponents.

• Determination of their stren and weaknesses, their full capabil and their shortcomings.

• Determination of the pre qualities required to make the mate more useful and the systems more liable.

• Determination of which mate are most likely to succeed as hardv and fuel in the Space Age.

• An aggressive research prog in those most likely to succeed, fle enough to change direction and em sis in the future.

Future solutions will require:

• Constant review of weapons defense systems—those in being, t in design and even those that are a wild gleam in some designer's eye

• Determination of extreme quirements of environment, invol temperature, stress, erosion, corro radiation, shock, friction, acous elements and expectable life of terials.

• Continuous review of all kn materials which show promise of solving any of the problems raise these environmental factors. Majo search effort should be applied in direction.

• A wedding of materials rese with fabrication research in orde achieve maximum results in both a

• Prospecting for new areas of terials research, keeping uppermo mind the environmental problems the directions of progress indicate accomplished research.

By putting first things first, by orienting our thinking to give a priority to basic materials research should eventually make it possible the systems designer to specify his terials requirements and fabric methods, and incorporate these ta made materials into his gimmick o morrow with a much higher degre reliability than he can achieve toc

*Washington District Manager Allegheny Ludlum Steel Corporation

Missile Troops in Italy

by Clarke Newlon

ıe following dispatch was sent Italy by M/R's Executive Editor, ouring Europe.

CENZA—The Western World's rmy missile command is stationed s part of NATO-earmarked forces are armed with obsolete weap- recently reduced in strength by and still a potent force because "mystery of atomic power."

ıe missile unit is part of the ern European Task Force AF) and operates under the and of Col. Melville B. Coburn. ıtil June of this year it had been with the *Corporal* missile and *onest John* rocket, both with nu- warheads. On June 30—by coin- e, perhaps, the end of the U.S. year—the two *Honest John* bat- were formally turned over to ılian army, which had been train- use them since Jan. 1. Simul- ısly, the command's personnel ut in half, from 4000 to 2000. he fact that we have obsolete least obsolescent weapons is not tant to the people of Italy," Co- said. "To them SETAF is a estation that there is an atomic in Italy and that it is here to It is a part of the mystery of power."

e recalled that last October his command loaded an *Honest John* wo USAF planes—a C-124 and 30—one carrying the rocket and her support equipment, and flew Salonika, Greece. There they fired th only a conventionally-loaded ad—at a target on the hillside.

Ve had no right to be that ac- ," said Coburn, "but we hit the dead center. The Greeks were ndously impressed that in just ours we had flown in and fired omic weapon. And when they us unload the rocket from the they were not at all sure it wasn't ningly atomic."

TAF itself is under the com- of Maj. Gen. John P. Daley and ated in Verona, some 33 miles Vicenza. In addition to the 1st Army Missile Command, it in- the SETAF Logistical Command rona.

Organized in 1955—In the spring 55 it became apparent that the an peace negotiations were headed l success, which meant the with- l of Allied troops from Austria. Thus NATO moved to create a new American military command in Italy as a defensive move to fill the void created by the neutralization of Austria, and SETAF came into being on Oct. 25, 1955.

The Missile Command still operates two battalions of *Corporals*, sky cavalry which would drop reconnaissance teams behind enemy lines in time of war, an engineering battalion and a signal company. It works with Italian forces to carry out atomic demolition. The area covered by the command is 175 miles broad and 100 miles deep, all of it roughly north of Vicenza.

Facing this area are the six passes over the Alps through which enemy invaders traditionally come. They are, from north to south, Resia, Brenner, Dobbiacs, St. Croce, Tarviso and Gorizia. The latter leads from the famed Ljubljana plains of Northern Yugoslavia.

In event of war, one of several major jobs facing the missile command would be demolition of these passes by atomic blasts. The Italians have the actual responsibility for destroying the passes, or making them impassable, but the missile command has control of the atomic demolition packages and the job of getting the Italian forces and the nuclear explosives to the scene.

To do this, the command has worked out three teams of three helicopters each. The first would carry the atomic store. This, it was revealed, weighs 1500 pounds, the same weight as the warhead of the *Corporal* and *Honest John*, regardless of what force the atomic blast may be. The second 'copter carries equipment and the third personnel.

MISSILEMEN of U.S. Army's 1st Missile Command, Southern European Task Force, supervise an Italian Army cadre servicing the *Honest John* solid-fueled rocket.

The Italians are expert, Col. Coburn said, in the art of destroying tunnels, bridges and roads. By boring a "room" some 40 feet into the side of a mountainside at just the right place to strike a "fault," they can, with the force behind an atomic blast, bring down the entire mountainside. Asked if they would close all the passes in the event of war, Coburn said, "Yes, if we were so directed."

• **Living by mobility**—The colonel feels that if war comes the primary job of his command is to stay alive by mobility. He said his force has shown that it can move the huge carriers of the *Corporal* and *Honest John* around the mountain roads of the extremely rough terrain of the area. In combat, the units would fire from one prelocated position and race to another, never firing twice from the same place.

Coburn said that each of the battalions turned over to the Italians was equipped with 254 *Honest John* rockets, but did not say whether all were nuclear-armed. The solid-fueled rocket weighs 5900 pounds; in a demonstration, an Italian Army team trucked one up, transferred it to the firing platform and theoretically fired it in about 10 minutes. It is fairly accurate at its 15.8-mile range.

The *Corporal,* two battalions of which the missile command retains, is fueled with nitric acid, aniline and compressed air. It is guided to the target by radar and has a range of 80 miles.

"The *Corporal,*" said Col. Coburn, "is either extremely accurate or horrible. And we're never quite sure which it will be."

Col. Coburn would like to have the *Sergeant,* a follow-on to the *Corporal* which is solid-fueled and much less complicated in its guidance system. In the event of war each of his battalions could get off four *Corporals* on the first day, if all went well, but only one each 12 hours thereafter, largely due to the preparation-for-firing complications.

• **Waiting for** *Pershing*—In addition to the *Sergeant,* which the colonel isn't counting on getting any time soon, he also has a great yearning for an 800-mile missile—typified perhaps by the *Pershing,* now under development by the Army, although its range will probably be more in the neighborhood of 500 miles at first.

ARPA Seeks 'Blue Sky' Defense Against Russian Missiles

More than $208 million has already been spent or earmarked for Project Defender—the search for something better than Zeus

by James Baar

"Come, we shall have some fun now!" thought Alice. "I'm glad they've begun asking riddles . . ."
—Alice's Adventures in Wonderland

WASHINGTON—Scratch a military man and he will tell you that sooner or later a relatively cheap and workable defense is found for every new weapon.

This is the faith that led the United States, through the Pentagon's Advanced Research Projects Agency, to put up $80 million in FY 1959 for research aimed at trying to find a "blue sky" defense against Soviet ICBM's.

The same faith encouraged the United States through ARPA to plan to throw another $128 million into the same program in FY 1960. As of now more than 30 private companies and institutions are taking part.

The program—called Project *Defender*—is of such fantastically increasing complexity that it makes such medieval problems as counting angels on the heads of pins appear easy by contrast. It involves study of such possibilities as death rays, anti-gravity machines and magnetic walls.

The glittering goal of the entire effort is the development of an ICBM defense that would be both much better and much cheaper than the Army's *Nike-Zeus*—the multibillion-dollar system being developed by **Western Electric** and **Bell Telephone Laboratories.**

The *Zeus* program is considered to be America's only chance to have an AICBM within the next eight to 10 years. It is scheduled to be operational in 1963.

• **In the dark**—"Maybe *Zeus* is the best kind of thing we can ever get," one top Pentagon scientist said recently. "But we feel there must be something else.

"We're like men in a pitch-black hallway looking for the key to a locked door. Maybe in the end we'll find there is no key at all. Or, maybe we'll find it in one of our pockets."

He shrugged and stared at a blackboard partly covered with half-erased formulas and sketches.

"You know, we really know so damn little about ICBM phenomena," he said. "That's what this research is all about. We're trying to find out more about it."

• **The fat pitch**—In its simplest form, the ICBM defense problem involves one nuclear-tipped ICBM hurtling toward you at a speed of Mach 24.

Let us say this ICBM is fired at you from Russia at 7 A.M. EST almost any day in 1961 as you sit down to eat breakfast in New York. It will arrive about 7:30, giving you hardly enough time to have a second cup of coffee.

However, you are not incapable of coping with this kind of threat to your breakfast and all future ones besides.

BMEWS, the huge radar system being constructed in Alaska and Greenland, is designed to alert you that an ICBM is on the way. Thanks to BMEWS, you would have about 20 minutes to do something about it.

If you had *Zeus* handy, which you won't in 1961, you could pick up the ICBM when it was about 10 minutes away with the powerful *Zeus* tracking radar.

The radar would feed tracking data into the big *Zeus* computer. That, in turn, would calculate the ICBM's trajectory, launch a *Zeus* at the correct moment and direct it to an i ception point.

You may now go finish your fee. But you won't do it in peace. have too much to worry about. ICBM threat is certain to get more complex.

• **Complications**—Russia is pected to have the capability to la a devastating ICBM attack on United States about 1962. More this capability is expected to incre and not just in numbers and relial

If the United States puts an o tional *Zeus* in the field in 1963, R is expected to be able to reply by ing the game a lot tougher.

Five or maybe 10 ICBM's cou fired at a target. Also, the sitt could be further confused by se along decoys of varying degre sophistication.

For example, the ICBM casing and engine can be blow after its propellant is exhausted, viding dozens of objects that w with the warhead along the sam jectory.

Some weight can be sacrific that balloons or somewhat heavie like decoys can be separated fro payload and follow the same traje

All of these would begin t their efficacy upon re-entry. But more weight could be sacrificed t vide heavier decoys which would late warheads re-entering the a phere.

Also, it may be possible to d low weight decoys capable of si ing a warhead both beyond and atmosphere.

Nor is this all.

• **And more complications**— payloads could be designed to

naff to confuse tracking. Warhead
it could be sacrificed to install
us types of electronic counter
ures equipment capable of jam-
and further confusing radar. And
type of radar shielding or absorb-
naterial may be developed.
inally, warheads can be divided
ght—and possibly their course can
tered. Instead of five or 10 war-
flashing toward a target, you
have 50 or 100 warheads pack-
actional yields all still more pow-
than the A-bombs that devastated
hima and Nagasaki.
ere then is the full threat: Space
ky are crowded with hundreds of

eably improved and the con-
use of *Zeus* would involve
omical costs. Therefore, they
d something else is needed. Here
's Project *Defender* begins.
efender, which absorbs about
of ARPA's annual effort, is
Harold N. Beveridge, formerly
erophysics Development. Dr.
rd Holbrook has been serving as assistant chief of ARPA's scientific missile defense branch while on leave from the **Rand Corp.** The program, in turn, is divided into seven areas including radar, interception, discrimination and advanced programs.

At present, the project's main work is to collect and evaluate large amounts of data on ICBM flight phenomena.

One way that this is being done is through minute observation of ICBM and IRBM flights from the Atlantic and Pacific Missile Ranges. ARPA maintains ships for this purpose off both the East and West Coasts.

Another way is through minute measurements of launchings of a special six-stage missile developed for ARPA by the National Aeronautics and Space Administration. It is capable of launching at relatively low cost a payload that re-enters the atmosphere at the speed of an ICBM. Launchings are being conducted at NASA's Wallops Island Test Center.

"We are looking for vulnerability," an ARPA official explained. "Where can we get at those warheads? How?"

• **Spending**—The 1959 ARPA budget provided $25 million for the study of missile flight phenomena. The 1960 budget provides $44,650,000.

Here are the budget figures for the program's three other major categories:

Identification and kill—$10,000,000 in FY '59, $17,600,000 in FY '60; radar and computing—$23,000,000 in FY '59, $35,250,000 in FY '60; exploratory research—$22,000,000 in FY '59, $30,600,000 in FY '60.

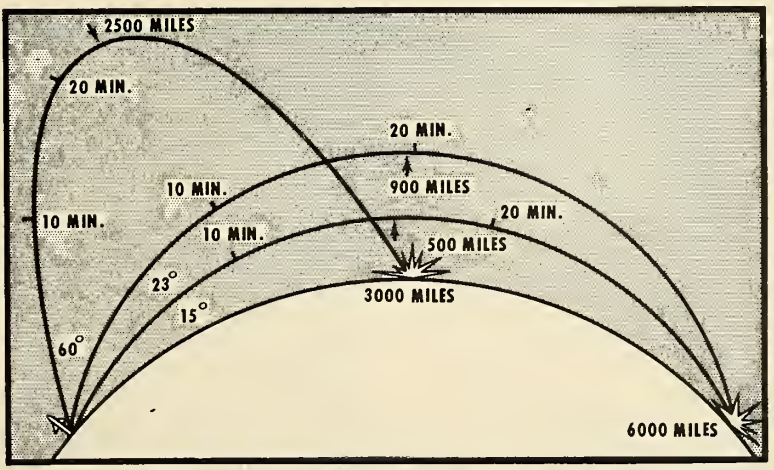
One of the most intriguing exploratory research projects is GLIPAR—the Guide Line Identification Program for Anti-Missile Research.

The first phase of the program—$1.5 million worth of contracts spread out among 12 firms—calls for thinking up and studying any "blue sky" idea that might lead within the next 20 years to an anti-missile weapon. The firms are to try to prove that the ideas are not feasible because they violate natural laws or some other permanent factor. Anything not rejected on these grounds will be considered for future investigation.

Meantime, ARPA has been conducting research and exploratory studies on such proposed anti-missile weapons as:

• Death Rays—The intense concentration of beams of electromagnetic radiation, causing incineration. A big drawback would be cost.

• Anti-Gravity—The search for some means to reverse the effect of gravity on an incoming ICBM. The missile and all other incoming objects would be hurled harmlessly into space.



• Giant Shields—The creation of a magnetic shield through which warheads and decoys could not pass.

• AICBM Spacecraft—The stationing in orbit of a manned space craft from which ICBM's would be intercepted shortly after they are launched—when they are extremely vulnerable.

"Money is very important in all this," an ARPA official said. "We want something that costs us no more to use against an ICBM than it cost the enemy to launch the ICBM against us. Otherwise, if it costs us a million every time he spends $100, he'll ruin us."

Obviously the most desired goal is to find something that costs a lot less than the enemy must spend.

"Put it this way: We want something simple and cheap," one official said. "Ideally, if we could have a bunch of monkeys armed with .22's sitting around the enemy's ICBM bases waiting for launching, we'd be all set."

AN ICBM with a range of 6000 miles could have any one of these trajectories. Trajectories show amount of reaction time available for interception by AICBM.

BRITISH ASTRONAUTICS

- *Armstrong Whitworth's Flutter Dart*
- *Rocketdyne's Dixon on storable propellants*
- *Astronautical conferences coming up*

by G. V. E. Thompson

LONDON—A rocket test vehicle that offers substantial economies in the investigation of aircraft wing flutter has been developed by **Sir W. G. Armstrong Whitworth Aircraft Ltd.** of Baginton, Coventry. Named the *"Flutter Dart,"* this test vehicle was exhibited at the International Transistor Exhibition held in London recently. The vehicle shown had been recovered after a test flight.

Armstrong Whitworth carrying out research into the problems of supersonic airliners, decided that a method of studying wing flutter cheaper than wind tunnel testing was needed (A.W.'s high-speed tunnel costs about $300 an hour to run). Another advantage of the *Flutter Dart* is that the speeds which the missile can attain enable the wings to be tested to destruction.

The vehicle carries strain gauges, equipment for measuring movements of the wing and control surfaces at supersonic speeds, and transistor amplifiers. The performance data are radioed to the ground. The illustration shows *Flutter Dart*'s electronic equipment being checked at the Company's laboratories.

•**Storable propellents**—T. F. Dixon, Chief Engineer of the **Rocketdyne Division** of **North American Aviation,** addressed the Royal Aeronautical Society on storable propellants recently. He said that while most of the liquid fuels in current use—alcohols, hydrocarbons, amines and hydrazines—were stable and easily handled, the oxidants did not comply with the definition of a storable propellent—one which can be continuously stored in a missile in a state of instant readiness for relatively long periods of time without evaporating or corroding the containing structure.

The fuel with the highest performance per unit mass—liquid hydrogen—also did not meet these requirements and special equipment was needed for its liquefaction, storage and transportation.

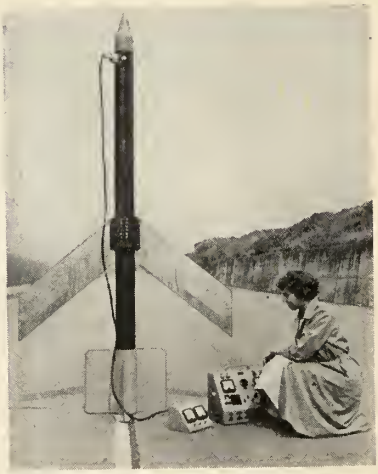
Storable propellants in use or under development had sea level specific impulses of 263-294 sec., but this should be raised to around 380 sec. in the next five years.

The present importance of storable propellants lay in the necessity for keeping ballistic missiles in a state of instant readiness for operational use. Their importance to astronautics would grow in the future: space vehicles undertaking flights of some duration and needing to use rocket engines to alter course would have to be fitted with efficient storable propellant systems.

• **Mk. 2** *Thunderbird*—**English Electric's** Mk. 1 *Thunderbird* (M/R, June 29) is vulnerable to radar countermeasures. As reported earlier, a more advanced Mk. 2 missile is under development. This will probably be fitted with constant-wave radar guidance, making it practically immune to these countermeasures.

Other advantages of constant-wave over pulse radar are the reduction in signal-to-noise ratio, greater range, greater accuracy, and ability to deal with low-flying targets. Constant-wave guidance may also be used with the **Bristol/Ferranti** Mk. 2 *Bloodhound,* now being developed.

• **British Commonwealth Spaceflight Symposium**—When last summer the British Interplanetary Society agreed to organize the Tenth International Astronautical Congress of the IAF (to be held in London, 31 August to 5 September) it was realized that the presence of delegates from the various countries of the British Commonw would make it possible for them to and discuss astronautical matter common interest. The BIS ther decided to precede the IAF Con with a short Commonwealth Space Symposium.



The decision of the British Go ment a few weeks ago to institu spaceflight programme has natu increased the interest in this sy sium, particularly as both industry the BIS consider that this progra is not ambitious enough. So man pers have been received from the craft and missile industry that i proved necessary to extend the posium to three days (27-29 Aug

At present the programme inc six papers from the Hawker-Sid Group **(Armstrong-Whitworth,** an **V. Roe),** two from the Indian A nautical Society, and one each **Bristol/Aerojet, de Havilland Pr lers,** Jodrell Bank Experimental St **Pye Ltd., Normalair Ltd.,** *The F cial Times,* University College Lo the College of Aeronautics, anc Weapons Research Establishment tralian Ministry of Supply). Other tributions are expected from C and New Zealand, and there wi a guest speaker from the U.S.

• **Missile salesmanship**—An rial in the London *Daily Herald,* paper of the British Labour criticized the country's missile aircraft sales methods. It said despite British achievement claimed by Western experts at the Air Show, "firms could not co against America's 'salesmen in uni and at the same time fight the a that the British Government and tary top brass show towards wi new orders."

The U.S.A.F. produced a Force" at the show complete command post, white-belted m police and massive equipment to American aircraft and missiles. In trast, Britain sent a Royal Ar captain and six gunners to demon the English Electric *Thunderbir* only when the firm had agreed t all the soldiers' expenses for the

Few orders came to British but U.S. sales were good.

announces and offers the services of its

MISSILE INDUSTRY LIAISON

More than 27,000 products are manufactured by Minnesota Mining and Manufacturing—the 3M Company. Every day, more and more 3M products are playing important parts in missile and space operations.

The technical and sales staffs of some fifteen 3M divisions, subsidiaries and groups make daily contacts with missile manufacturers and subcontractors. Their efforts are implemented by 22 divisional and four staff research laboratories.

However, like the missile industry, the 3M Company is a growing *and a diversified* operation. The use of 3M products and capabilities increases every day.

To further serve this growing, diversified industry, 3M has formed the Missile Industry Liaison. This group, staffed by technical personnel experienced in rocket propulsion and other phases of space technology, is well qualified to translate *your problems* to those 3M specialists in your field of interest. Too, information on all 3M Company products—or interests applicable to missile research, development or production—is thus available to you through *one* convenient source.

For a cross-section view of 3M Company products for the industry, send for your free copy of the brochure "Products and Capabilities." Write: Missile Industry Liaison, 402 McKnight Road, St. Paul 6, Minnesota.

The Missile Industry Liaison is associated with these 3M divisions and subsidiaries:

Zenith Plastics Company
Reinforced Plastics Division
Electrical Products
American Lava Corporation
Irvington Division
Mica Insulator Division
Magnetic Products Division
Central Research Group
Mincom Division
Duplicating Products Division
Reflective Products Division
Industrial Trades Tape Division
Mid-States Gummed Paper Division
Chemical Division
Adhesives, Coatings, and Sealers Division

For more information on 3M products, contact your 3M representative or the Missile Industry Liaison, 402 McKnight Road, St. Paul 6, Minn.

The AF's 'Integration' Approach

How the Aeronautical Systems Center moves into responsibility for management of a weapon system after a decision is reached putting it into production

by Betty Oswald

WASHINGTON—"Integration," a word quently in the news, has a very ial meaning in the Air Force. It s not with race relations but with equally difficult job of fitting to- er all of the jigsaw pieces of a on system. It deals also with the of welding into a smooth-running all of the divergent interests h must be considered in converting eapon system into an operational on in the hands of the troops.

We have seen in earlier M/R stor- hat the instrument of integration is Weapon System Phasing Group and Weapon System Project Office, aged in its early phases by Air arch and Development Command in later stages by the Aeronau- Systems Center of the Air Ma- l Command.

• **Enter ASC**—ASC comes into the re as manager of the integration t only when a decision is made the weapon system has reached int warranting a production order. latively new organization, ASC is operating arm of Air Materiel mand in all areas except ballistic iles.

This means it handles management e weapon system during the period production for inventory. In the er phases, when ARDC has execu- management responsibility, the r agency is still responsible for urement. The key man during this e is the contracting officer respon- for the contract—how it is writ- and what it contains. He is as- d to the weapon system project e.

n some cases, the prime weapon m contractor is made responsible certain subsystem development or production. In such cases ASC ws proposed subsystem sources, g a subcontract advisory panel, to re maximum consideration of the rience and technical programs of AF and industry. Review involves questions as the technical capa- y of the subcontractor; manage- t approach to development and test; luction capabilities and facilities; performance in meeting schedules; quality control; overall company management structure and costs.

• **AF control**—AF reserves the right to reject the contractor's recommendations. As soon as possible, a decision is reached on so-called "make or buy" plans which involve such questions as maximum utilization of available industry capacity; minimum acquisition of new Government facilities; maximum use of specialized industries; maintenance, if possible, of a healthy basic aeronautical industry; maximum competition; utilization of small business to the greatest extent practicable; maximum use of standardized components, and elimination of unnecessary duplication of development. After they're agreed on, these plans can't be changed without prior AF approval.

Once this is done, AF keeps its finger in day-to-day management of the project. Each contract is assigned to an administrative contracting officer who—in the case of a major contract—will normally be in an AF plant representative office at the contractor's plant, to which specialists in cost analysis, quality control, production, property administration and audit are assigned.

His link at headquarters is the Weapon System Project Office at ASC. Headed by Maj. Gen. Beverly H. Warren, the organization is composed of seven directorates: contract support; logistic support; strategic systems; air defense systems; tactical and support systems; equipment and services, and the directorate of resources.

In addition, Gen. Warren has under his command the Aircraft Production Resources Agency on which representatives of the Army, Navy and AF serve. This agency's job is to schedule production of what have been termed "aircraft common components" and to be sure that the necessary materials are available.

Also part of Warren's organization are a program and analysis office and an office which provides management services.

• **How it's divided**—Under the directorate of strategic systems are weapon system project offices for the B-52H, the B-58, and the KC-135 tanker, for which ASC has executive management responsibility. In addition, there are Weapon System Project Offices for the B-70, for which ARDC is responsible, as well as undescribed advanced systems, strategic missiles (air breathers) and the *GAM 77/72—Hound Dog* and *Quail.*

Weapon System Project Offices reporting to the directorate of air defense systems include: F-106, F-101, F-108, *Bomarc* and drones. In the directorate of tactical and support systems, there are Weapon System Project Offices for the F-105 Thunderchief, transports, trainers, F-104, Star Fighter, tactical missiles and helicopter liaison.

The directorate of equipment and services is divided into divisions including accessories, weapons guidance, propulsion, communications and reconnaissance, specialized procurement, and Government-furnished aircraft equipment (GFAE).

The directorate of resources is responsible for industrial facilities, manufacturing methods (breaking the producibility barrier) and materials control.

• **Beefing up**—Actually, the idea of the Weapon System Project Office is not new. What is new is the way that the office has been beefed up in importance to serve as a focal point in the cradle-to-grave support of the weapon system.

This means among other things that while the program is in its research and development phase, as well as in the production phase, such requirements as maintenance and supply, along with training and operations, are cranked into the Weapon System Project Office—to provide an operational system which is entirely maintainable at the earliest possible time.

It also means that when the weapon system finally passes through production and the problems are only those of logistic support and maintenance, executive management responsibility moves out of Dayton to one of the Air Materiel Areas which have been given responsibility for support (spares, etc.) and maintenance of the weapons.

Even then, ASC and ARDC handle such questions as product improvement and technical failures.

Printed Circuitry Pays Dividends

An M/R survey finds missile business has helped to spur rapid growth of circuits that enhance reliability, cut assembly costs and permit fast repair

by Charles D. LaFond

WASHINGTON—The growing trend toward miniaturizing and modularizing electronic equipments, particularly in the missile industry, has brought rapid development of small, highly compact wiring assemblies, known throughout the industry as printed or etched circuits.

Although these circuits were not originally developed for direct application to missiles, certainly the missile business has provided a goodly share of the incentive needed to promote their growth.

The need for lightweight, extremely compact electronic equipment in miniature and subminiature assemblies called for something other than heavy bundles of inter-connecting cables and wires. New techniques have evolved better products, and new equipment for the production of printed circuits has resulted from this increasing effort throughout industry. Along with the increasing need for microminiaturization, industry has kept up with its small printed circuit cards.

The use of printed circuits has aided equipment design improvement and has greatly helped to increase reliability and cut assembly costs of complex equipment. At the same time, the new and equally complex packaging has contributed to improved component mobility. In addition, of course, modularization simplifies maintenance, increases equipment flexibility through rapid interchangability of units, and in general permits rapid repair in almost any system.

Besides its other physical attributes, probably one of the strongest arguments for the use of printed circuitry in missiles and rockets is its inherent ability to withstand heavy vibration and shock. A most troublesome area in conventional wiring is separation of soldered joints under an environment of high vibration or sudden shock. With the passage of time and the normal acquisition by manufacturers of increased experience, quality products are now available that employ almost unheard-of tolerances. New techniques permit high reproducibility, faster and cheaper.

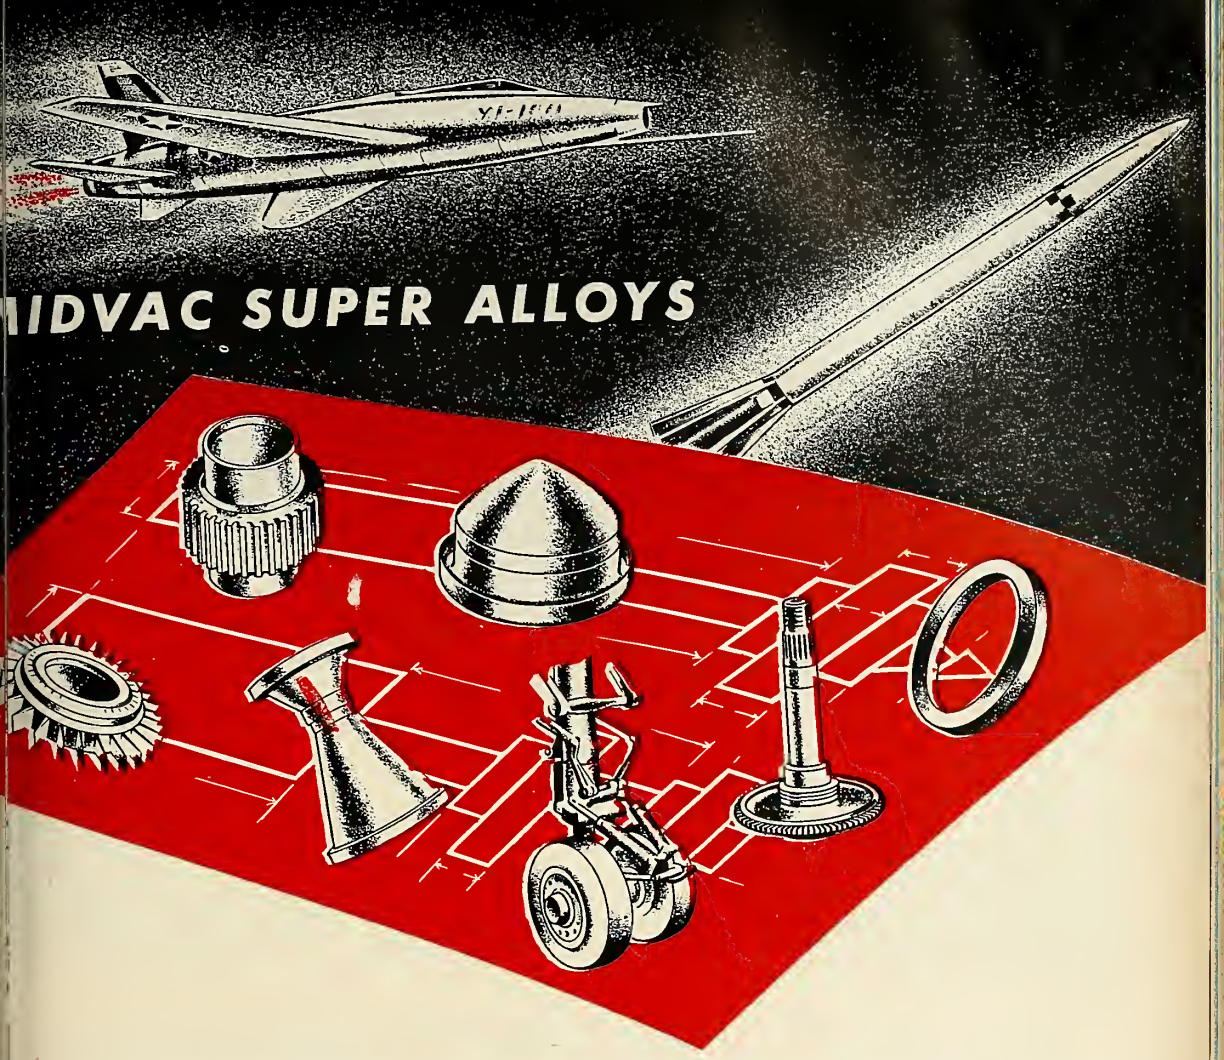
MISSILES AND ROCKETS recently conducted an industry survey to determine progress in the field of printed circuitry in the past year. Here are some of the highlights of the survey returns.

• **Printed circuit usage—Burroughs' Military Electronic Computer Division,** a prominent manufacturer and user of printed circuitry, produces between 30,000 and 40,000 circuit boards per month. This is extremely high volume production, yet Burroughs maintains that to date they have not had to replace a printed circuit card in any device now in use in the field.

An indication as to just how much printed circuitry is in use is revealed by Burroughs's estimate of 95% for the equipment they produce. A company spokesman said, "We range the AN/FST-2 in SAGE, which about 65% printed circuits, to the ground guidance computer which ploys about 95%.

"In some equipment, the circuit are entirely by printed boards. Some our basic design equipment does contain printed circuit cards, but new models do, as well as the peripl devices linked to them."

• **Microminiaturization**—Alth actual application is still highly cl fied, Burroughs Research Cente Paoli, Pa., has indicated that it is microminiaturized blocks extensivel research and development and ex to make heavy use of equipment reduction techniques in the future. One spokesman went so as to say, "in ten years, you won't anything but micromodularization electronic equipment.



The company's new packaging t nique, which increases a module ca ity to 300 components per cubic i was revealed here last week at the stitute of Radio Engineers' 1959 tary Electronics Conference. The roughs high-density packaging achieved through "macro-modula tion" of components already mi miniaturized.

The new stacking technique, w decreasing total packaging volume available surface areas, provides munity to thermal and physical sh in environmental conditions. The c pany has also indicated that along these attributes circuit interconnec and power input requirements been controlled in equipment des

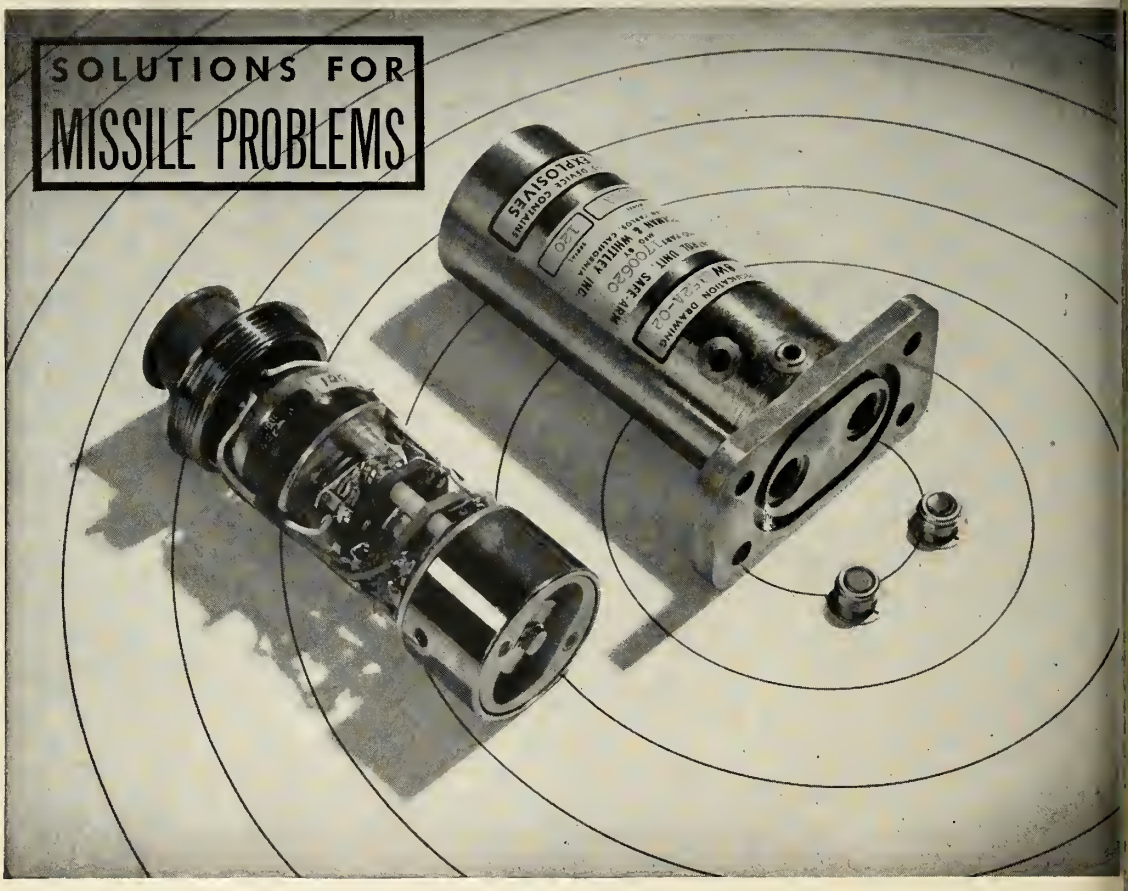
NEW TECHNIQUE by Burroughs Corp. in micro-miniaturization of electronic components. The small wafer was miniaturized from a printed circuit board some 20 to 30 times larger.

OLVING MODERN DESIGN SPECIFICATIONS

Parts for Missiles—Rockets—Jet Engines are constantly calling for newer alloys to operate at higher temperatures. Alloys made by the Midvac process of consumable electrode melting are currently answering these needs and new ones are being developed in anticipation of more critical operations.

Midvac Alloys insure increased tensile and impact properties, improved stress rupture strength at elevated temperature, and longer fatigue life.

Standard commercial alloys can also be made with increased cleanliness resulting in higher properties than have been available under conventional means.



Offered in ingots, billets or forgings for the production of missile combustion chambers, tail cone assemblies, jet engine parts, aircraft landing gear components or any other parts requiring properties beyond the capabilities of conventional steels.

safe/arm initiators

Ten years of pioneering in the missile component field has made possible this new line of Beckman & Whitley solenoid-operated safe/arm explosive initiators. Unit on the left has cover removed to show internal arrangement.

Weighing only 1.85 lb loaded, this model is 5 in. by 3 in. by 1¾ in. It was designed to military requirements. It can be armed or disarmed by remote electrical signal and includes both visual and electrical telemetering facilities for indication of armed or disarmed condition. On reception of a command firing signal, the unit will initiate associated primacord, low-energy detonating cord, (LEDC) or bulk charges.

This may be just what you need. On the other hand, Beckman & Whitley can provide the engineering capability, the production facilities, and perhaps most important, the speed necessary to give you anything you *do* need in the line of propellant-actuated devices.

Just tell us your problem.

Beckman & Whitley INC.

ariety of approaches

lopments at Burroughs are shown to ustrate the evolution in miniatur- ng systems. Note that the tempera- re rise from 55°C to 100°C was ac- mpanied by a power increase from 0 watts to 2200 watts.

To achieve 100°C operation, sili- n transistors were employed effect- g a power input rise. At the same ne power dissipation increased, vol- ne decreased (it should be noted that e increased concentration of power ssipation per cubic foot was solved this instance by integrating an effi- nt heat exchanger into the overall uipment design).

A basic design philosophy held by e company is that the circuit must be ilt essentially in two dimensions, with e system being in the third dimen- n. In the macro-module technique, e true two-dimensional form is ughly maintained. As components d circuitry become smaller, this in- -connection technique may prove to the principal element in a given com- x assembly. By retaining the third mension for the system, with con- uing miniaturization, this dimension comes largely available for system ring.

As a result of the macro-module chnique, they have achieved a quick oduction capability, principally be- use the design permits the acceptance components from many vendors. ese components can be tested prior assembly into circuits and the cir- its can be assembled prior to final sembly. The final assembly then can tested before the complete unit is aled.

• **ITT's approach**—Another pioneer the development of miniaturized stems employing printed circuits is e **International Telephone and Tele- aph Laboratories.** Since missile pay- ads require extensive weight and e reduction in electronic units, this mpany has taken the approach that mponents, because of microminiatur- ation, will have to be produced with improved ability to withstand high mperatures. The smaller size for heat ssipating components such as resis-

ORIGINAL artwork for printed circuits in sub-miniature assemblies is drawn twice desired size, reduced photographically. Ryan technician checks camera.

tors implies a need for materials having greater heat stability.

ITT believes that the increased use of small semiconductor devices because of their very rapid development has gone far ahead of the normal evolutionary size reduction of resistors, capacitors, etc. The problem is that these components are still scaled and sized to accommodate vacuum tubes.

Based on their early experience with small printed circuit amplifiers for time proximity fuses, the ITT Missile and Space Systems Laboratory has been employing similar techniques to develop printed circuits, and small components for use with them, to a point of reliability and practicability acceptable for missile and space usage.

The Lab chose as its starting point its DOVAP telemetering sub-carrier oscillator. This is a transponder in wide use in missile testing as a doppler-measuring, projectory data-gathering system. The resulting metamorphosis in the sub-carrier oscillator from the conventional wire version to the final subminiature printed component device that has resulted from their efforts is shown in the photo at top of page 26.

To achieve this great reduction in size, new equipment for the production of carbon composition printed resistors had to be constructed. Work is still continuing at the Laboratory in developing techniques for the practical fabrication of printed subminiature circuits.

Because resistors constitute more than 50% of the circuit components in general, a major effort has been assigned to the area of subminiature carbon composition and metal film resistors. There are other attributes of printed resistors beyond that of mere size reduction. Resistors in a similar range can be printed several at a time. They need not be inserted into a circuit and the size may be almost a strict function of dissipation required. The lab also believes that printed resistors offer maximum potential for completely automated production. In addition, printed resistors need not be handled—a primary reason why, in their opinion, conventionally designed small resistors do not enjoy wide application.

• **High-quality production—Avion-Alexandria,** a division of **ACF Industries, Inc.,** has had its own printed circuit facility in operation for four years. Of prime concern to the company has been development of processes aimed at producing unusually high quality etched boards.

To achieve this, the company has developed what it believes is better-than-usual processing equipment. The results are best shown by an example of the tolerances achieved in production: spacings ±0.001 in. conductor widths and lengths ±0.002 in.; registry front and back ±0.002 in.

In addition to normal printed circuit boards and assemblies, the company has developed high-quality printed circuit techniques for rf stripline components including filters, couplers, and power dividers.

• **Advanced facilities—Ryan Aeronautical Company's** latest—and most modern in equipment—is a new photographic facility designed and equipped especially for manufacturing printed circuitry.

Since printed circuits must be treated, by means of photographic processes, to enable the narrow silver-plated lines to conduct electric currents, Ryan considers the new photographic unit a necessity for its missile subsystems. The facility was planned and equipped for the express purpose of manufacturing etched boards with the greatest dispatch and accuracy.

Highly compact, the photographic unit covers only 364 square feet of space. Windowless, to eliminate drafts and dust and to keep out the fluorescent

Multiply Time	512 Micro Sec.	75 Micro Sec.	40 Micro Sec.

light of the adjoining electronics laboratory, the unit is air- and temperature-conditioned. Its construction is such that hallways and shielded doors completely screen off light and activity in one room from light-sensitive work going on in another room. The whole facility is operated as a "clean" room.

The precision photography applied to intricate miniature boards is achieved with a select collection of equipment—$7000 worth of the finest industrial photographic apparatus, according to the company.

In addition to three major electronic projects—automatic navigator, helicopter hovering device and missile guidance systems—Ryan has more than a dozen others under development, each calling for subminiature electrical assemblies based on printed circuitry. The program places great emphasis on the need for an integrated, modern facility for supplying precision-built circuits on a production line basis. Already set up to turn out a board a minute as a one-man operation, Ryan believes that printed circuit photographic units can easily increase this rate.

A new and highly versatile equipment that appears to be an asset to printed circuit production, has been revealed by the **Fuller Brush Company** of Hartford, Conn. Called a printed circuit pumice scrubber, the unit scrubs, rinses and dries printed circuits and laminates in one operation. The machine will also prepare items for masking, etching and soldering in less time than by conventional means, Fuller says. Operating at a rate of 5 to 15 feet/minute, it will: (1) remove all surface dirt and oxide; (2) with a dip, remove all photo-resists after etching; (3) prepare plates for more effective soldering; and (4) deliver plates clean and dry.

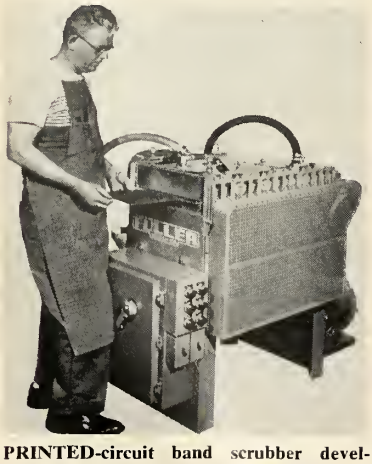
CONVENTIONAL wired subcarrier oscillator is shown at rear, printed circuit chassis in the middle, and a subminiature printed component device at front.

• **New material**—Another recent innovation in printed circuit development is the use of a new material developed by **Corning Glass Works** at Bradford, Pa. Copper metalized printed circuit boards made of high-strength, high-temperature Fotoceram have been produced by the company for high-reliability military applications for missile guidance and communication systems.

Automatically produced by a chemical machine process which permits extreme accuracy, the boards are capable of continuous operation between minus 55°C and 250°C. Through-hole plating is standard and repeated resoldering does not result damage on circuit runs, according Corning.

Fotoceram is a crystalline vari of Corning's Fotoform glass and a flexural strength of 25,000 ksi.

In processing, the original pho sensitive glass is exposed through ne tives to ultraviolet light and board holes are then etched out subsequent heating and immersion a dilute hydrofluoric acid. Finally, ditional heating converts the glass i a crystalline state and the circuit p is applied to the board.



The company has said that in ad tion to its high thermal endurance, Fotoceram board will not bow, be warp, or burn and is impervious to s vents.

Vibration tests recently perform on the boards indicated that they w withstand more than 60 g when pr erly mounted.

In tests performed on Fotocera circuits components have been ha resoldered to the same circuit run m than 50 times without indication failure. To test solder-heat resistan the circuit boards have been floa or immersed in 565°F molten sol for over five minutes without evide of any blistering or lifting of circ runs, a company spokesman said.

• **Plated-through holes**—A sn controversy has arisen among ma users of printed circuit boards w feel that eyelets and plated-throu holes cause unreliable assembl **Packard Bell,** for example, prefers use soldered leads inserted throu holes in the boards.

In the July 27 issue of M/R, will present a defense of the use plated-through holes based on the sults of a test program performed **Motorola's Military Electronics D sion.**

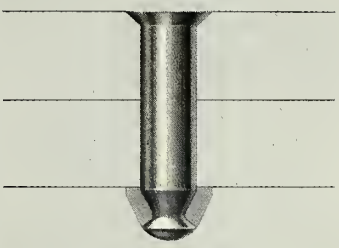
PRINTED-circuit band scrubber developed by Fuller Brush Co., Hartford.

PHOTOSENSITIVE glass is processed at the new Corning Glass Works plant at Br ford, Pa. Each rectangle will be a printed circuit board for high temperature u

THE BOEING IM-99 BOMARC . . . *is a long range, extremely high altitude supersonic missile designed to intercept and destroy enemy aircraft and missiles. In full production, it has a greater range than any other air defense missile.*

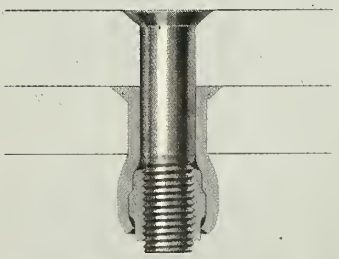
STRUCTURAL EFFICIENCY CONTRIBUTES TO GREATER PERFORMANCE

The airframe of the Bomarc reflects a successful solution to structural and fastening design problems typical to high performance missiles and aircraft. The airframe combines high strength with high temperature resistance, without adding unnecessary weight which could effect performance.



Three different fastener problems in the Bomarc are solved by stainless steel Hi-Shear fasteners. Hi-Shear Rivets are used in structure subjected to engine and rocket boost heat . . . Hi-Torque Bolts fasten removable panels and the nose section where heat, surface smoothness and ease of removal are factors. Blind Nuts eliminate hole/nut coordination problems in congested areas.

Continuing fastener environmental studies are being conducted at the Hi-Shear Test and Research Laboratories in a variety of strength and temperature resistant material combinations for advanced structural requirements.



HI-TORQUE BOLT

IDEAL FOR FASTENING STRESSED ACCESS AND CLOSE-OUT PANELS. ITS UNIQUE SHALLOW RECESS LOCKS THE DRIVER INTO IT WHEN A HIGH TORQUE LOAD IS APPLIED DURING INSTALLATION OR REMOVAL.

HI-SHEAR RIVET

HAS THE LIGHTEST STRENGTH-WEIGHT RATIO, LEAST PROTRUSION AND LOWEST COST OF ANY SWAGED TYPE FASTENER. INSTALLED WITH STANDARD RIVET GUNS OR SQUEEZERS FITTED WITH HI-SHEAR RIVETING SETS.

BLIND NUT

FOR BLIND OR OPEN APPLICATIONS, THE BLIND NUT CUTS PRODUCTION COSTS BY USING ONE HOLE INSTEAD OF THE NORMAL THREE REQUIRED FOR NUTPLATES. INSTALLATION SPEED IS ABOUT TEN PER MINUTE BY ONE MAN USING A LIGHTWEIGHT, HYDRAULICALLY OPERATED GUN.

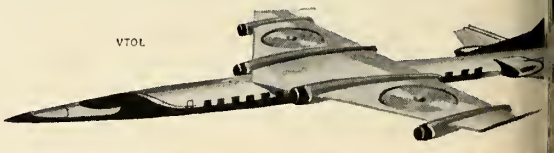
Space Transports
are under development now, capable of transporting a pilot and 1000 pounds of payload or three passengers—equipped to work in s —to an orbit of 1000 miles altitude Indications are that an operationa vehicle will be feasible and practic in the 1965 period.



FOR FUTURE DECADES IN SPACE... *another Lockheed Progress Report to Engineers*

Plotting the nation's future space exploration projects requires the capabilities of a forward-looking company; one with vision, superiority in technical skills and advanced facilities. Lockheed, Burbank, long a leader in extending the science of flight, is placing its vast resources and accumulated knowledge into programs designed to provide major breakthroughs in the fields of: Basic and applied research; manned aircraft of advanced design; missiles and spacecraft. Shown here are artists' renderings of a few of these important projects. Such project diversification calls for high-level technical skill, offers genuine challenge to experienced engineers. At Lockheed these varied projects require engineers in many fields. Take advantage of this need. Go forward with a forward-looking company: Lockheed, Burbank.

Supersonic Transports—have held an important place in our thinking for the past several years. Extensive wind tunnel tests have been conducted on many design concepts, supplemented by exhaustive laboratory and structure studies. Lockheed is prepared to build an airliner that will travel at speeds in excess of Mach 3 at an altitude of 75,000 feet.

Infrared Systems studies are being conducted us advanced method of detecting fast-moving missiles and high aircraft. A new facility, which includes an advanced labor with an infrared tunnel, for basic research and developm prototype equipment in this expanding field, has been set push Lockheed, Burbank, to the forefront in infrared stud

Vertical Take-off and Landing Projects— heed, Burbank, is engaged in exploring the potential of projects on a very broad scale. Different VTOL features are e ied in each proposal. Considerable emphasis is being plac VTOL "air recovery" vehicles, designed for air rescue and r missiles recovery missions.

Solar Radiation Studies—are being conducted at heed's flight test radio station at Briar Summit, California, p particular emphasis on solar flares as our contribution to the national Geophysical Year. We have already accum more than a quarter of a million images of the s analysis. In cooperation with other companies, v determine the processes by which solar energy is re

High caliber scientists and engineers are invited t advantage of Lockheed's outstanding career opportunities. ings now exist in: Electronics; aero and thermodynamics; p sion; servo-mechanisms; materials and processes; structur stress; operations research; research in optics, infrared, acc magnetohydrodynamics, instrumentation, mechanics and h lics; mathematics; and in all phases of design. elding Process Gives Good Control

A new welding process, called ort-Arc," welding has been deoped by **Linde Company,** Division **Union Carbide Corporation.** It pers manual and mechanized welding hin material with excellent control he weld puddle.

The outstanding feature of this new t-gas consumable-electrode process he ability to make manual fusion ds in the range of thickness of 0- to .100-in. of all common metals, h as carbon steel, stainless steel, minum (.040 in. minimum), copper, t, in all positions and types of joints.

The "Short-Arc" process exhibits rent advantages over other welding hods for welding sheet metal by viding a more-readily-controllable ing process at high welding speeds, er production of fillet welds, ability weld in all positions, and—of sigant importance—the ability to weld t metal in a range of thicknesses tofore not considered readily weldby any process.

Successful operation of the process ended on the development of several factors: proper power source, ction of shielding gas, and appas for feeding small diameter wires.

Normal fusion welding operations g conventional type power supplies either covered electrodes or inert-shielded processes, give too much and cause uncontrolled melting when making butt, lap, or fillet welds in thin gauge material. The Linde "Short-Arc" process has been made possible by the use of constant potential power supplies incorporating a drooping characteristic.

With the development of this new type of power supply it was found that surge currents could be controlled to limit the time duration of arc outages, prevent wire ejection, and produce a stable buzzing type of arc. This arc, operating in the range of 30 to 125 amp., 14 to 19 volts, short circuits dozens of times per second.

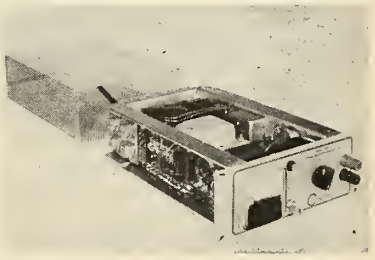
This produces a small cold puddle pinpointing the location of the arc heat and enabling the welding of thin materials in all positions. It is used primarily with .030-in. diameter wire, although .020-in. diameter hard wire works well on material in the very low end of the thickness range.

Considerable study has been given to evaluating shielding gases and mixtures and selecting the best in each instance. Argon has been found suitable for most metals such as aluminum, copper, and Everdur. For stainless steel and carbon steel, argon-oxygen and argon-carbon dioxide mixtures are finding wide acceptance.

Pure carbon dioxide is being used for some steel applications, but it produces somewhat more spatter and poorer head formation. The use of argon-carbon dioxide mixtures provides many advantages over either argon or straight carbon dioxide on carbon steel. Their use provides superior wetting action with the minimum amount of deposited metal resulting in a vastly improved bead contour. An approved mixture is now commercially available.

A key factor in the success of "Short-Arc" welding was the development of both manual and mechanized equipment to feed wires as small as .020- or .030-in. diameter.

The process is easy to use. Very little training is required for adaptable personnel. Manual welds can be made readily in all positions on most commercial light-gauge materials.



The Linde "Short-Arc" process makes high quality welds quickly and economically in carbon steel, stainless, aluminum and other metals. Distortion is minimized due to the pinpoint-type arc and there is little or no post-weld cleaning. Joints with poor fit-up are easily accommodated with manual welding. For example, ¼-in. gaps on 14-ga. carbon steel have been bridged with ease.

Solid State Power Supply Is Short Circuit Proof

Electronic Research Associates, Inc., announces new model additions to their Magitran line of solid state power supplies which combine the characteristics of magnetic and transistor regulators.

These new units are intermediate current types, and like the high current units of the line, offer full automatic

protection against all types of short-circuits or transients, either on an intermittent or continuous basis, with instantaneous recovery.

Other advantages include fast transient response, transistor dissipation independent of line voltage variations, close regulation, low ripple content,

continuous wide-range adjustable output, instant warm-up time, and many other features.

These units are of the space-saving type, with panel dimensions which are multiples of the standard 19-inch relay rack, and two units may be mounted horizontally in the standard rack dimension. These models are intended for all types of laboratory and equipment application.

In these new designs, the properties of a special magnetic control are combined with the fast transient characteristics of the transistor regulator. Pre-regulation and line transient protection is achieved by the magnetic controller.

This component is also designed in a manner so as to provide zero output in the event excessive current flows due to overload or short in the external circuit. The transistor regulator accommodates all fast line or load variations and transients, as well as providing for ripple reduction. This combination results in minimum heat dissipation for all transistors independent of line voltage variations.

Under short-circuit conditions zero voltage appears across the transistors and thus complete protection is obtained under the most extreme conditions. Other design features include the use of differential dc amplifiers, compensated zener references, silicon rectifiers, and conservatively rated transistors and components. Despite the advantages of the design, units are conservatively priced.

The new models have been given the model designations of 202M and 203M.

The Model 202M provides adjustable output over the range 10-150 VDC at 0-200 milliamperes, and the Model 203M has an output adjustable over the range 10-300 VDC at 0-200 milliamperes.

Other specifications common to both models include input, 100-130 VAC, 60 cps; line and load regulation, within 0.05%; ripple, less than .005%. Units are for bench or sub-relay rack mounting, and panel dimensions are 3½ x 9½ inches.

Miniaturized Choppers Have Varied Uses

A series of general-purpose miniature choppers, designed for aircraft and line frequencies, has been developed recently by **Collins Electronics Mfg. Corp.**

The choppers are now available in single-pole double-throw, or double-pole double-throw types, 60 cps or 400 cps, in both make-before-break or break-before-make designs.

Miniaturized for space and weight economy, they are hermetically sealed and drygas filled for operation in any known climate. To make insertion and removal simplified, as requested by field servicing firms, these Collins units have connections brought out through the base.

Maximum noise created is 450 microvolts across 1 megohm at 400 cps. They have been designed to meet all applicable military specifications.

Thin Gaged, Large Sheet High Alloys Available

Haynes Stellite Company, Division of **Union Carbide Corporation,** has just announced the availability of several high-temperature alloys in wider cold-rolled thin-gage sheets than were previously available. Sheets measuring 0.010 in. thick, 36 in. wide, and 96 in. long are now being rolled as a result of recent refinements in technique at the Company's expanding wrought alloy facilities.

This development, virtually an industry "first," opens new markets for high-alloy sheet where size limitations were an intolerable restriction to its consideration for certain applications.

Several companies are now investigating the use of large thin sheet as outer skin material for space craft,

shrouding for hot sections of conventional jet aircraft, or facing sheets for honeycomb constructions.

Alloys currently available in sheet form are "Haynes" alloy No. 25, "Multimet" alloy, "Hastelloy" alloy R-235, "Hastelloy" alloy X, and General Electric's "Rene 41" alloy. These alloys are among the leading materials in the field of high-temperature metallurgy.

Marking Method Speeds Identification of Bearing

A new method of speedy, infal visual identification for tiny instrur bearings—overcoming a long stan problem of the industry—is curre being introduced by **New Hamps Ball Bearings, Inc.**

Specifications occasionally call bearings about the size of the pe at the end of this sentence. The o and inner rings of the bearing, th fore, do not allow much room identifying markings.

New Hampshire Ball Bearings, solved this problem through a ra simple but effective method.

TOUJOURS L'AMOUR

Seven 1-megacycle video channels on a single half-inch tape — that's why there's an affectionate reaction everywhere to the new Mincom Model CV-100 Video Band Magnetic Recorder Reproducer. Tape speed of 120 ips, plus special recording and playback heads, produces reliable frequency response from 400 cycles to 1.0 megacycle (each track). Only 12 moving parts, four simple adjustments. Only 0.1% flutter and wow. No mechanical brakes. All plug-in assemblies, carefree maintenance. Interested? Write for specifications.

3M COMPANY ... WHERE RESEARCH IS THE KEY TO TOMORROW

MINCOM DIVISION MINNESOTA MINING AND MANUFACTURING COMPANY

2049 SOUTH BARRINGTON AVENUE • LOS ANGELES 25, CALIFORNIA

Circle No. 10 on Subscriber Service Card.

Sets of double lines, either 120° or 180° apart, applied to one face of the outer ring, supply three important pieces of information at a glance.

First, the marks indicate whether the bearing is made of Stainless Steel (120° apart) or Chrome Steel (180° apart). Second, that the precision instrument bearing is ABEC 7 tolerances, or better. And, third, for inventory and specification purposes, that the bearing is made by New Hampshire Ball Bearings, Inc.

The new method of marking was introduced after careful analysis proved that it produced no change in dimensions, no distortion, or destruction of surface finish, and does not affect mounting or performance of the bearings. This is because the marks are applied on the outer ring by impact before grinding and heat treating.

4-Stage Amplifier Claimed To Be World's Smallest

What is said to be the smallest 4-stage amplifier ever constructed is now available in production quantities from **Centralab,** a division of **Globo-Union, Inc.**

Measuring only 0.531″ in diameter and 0.228″ in height, including the hermetically sealed case, the unit contains 12 resistors, 5 capacitors, and 4 transistors. It weighs 1/16 of an ounce. According to Walter E. Peek, Centralab's General Sales Manager, this means that the amplifier has a component

density of well over half a million components per cubic foot.

Mr. Peek emphasized that this is not a developmental unit or laboratory curiosity, but is in actual production, and is now being delivered to a number of leading manufacturers. It has application in hearing aids, computers, missiles, and a variety of other military electronic devices.

The new unit is known as the TA-12, Mr. Peek said. Prior to its development, the smallest available 4-stage amplifier was Centralab's TA-11, which measures 1.175″ long x .250″ wide x .665″ high.

The TA-12 has a gain of 73 to 78 db at 1 KC with 1000 ohm load. Its nominal input impedance is 2000 ohms. Signal to noise ratio is 42 db below 1 volt. Supply voltage is from a 1.3 volt mercury cell; current drain is 2.1 milliamperes maximum. At 300 CPS the frequency response is down 6± 3 db; it is down 4± 2 db at 3000 CPS. Load impedance is 1000 ohms inductive load with 400 ohms maximum d.c. resistance. According to Mr. Peek, these standard performance limits may be modified for special applications.

Tiny *Vanguard II* Motor Commercially Available

Inside *Vanguard II,* the weather satellite which is expected to be orbiting for several hundred years to come, is a tiny two-ounce motor, installed to drive a miniature tape-recorder. In size, it is the only one of its kind, but it was manufactured by the **A. W. Haydon Division** of **Consolidated Electronics Industries Corp.** for the Army Signal Corps as a scaled-down version of the Company's standard DC model.

This sub-miniature motor enabled the weather satellite to respond to interrogation, on command from certain of Earth's monitoring stations, 152 times during its first 211 cycles before the transmitters ceased operating, according to the National Aeronautics and Space Administration. *Vanguard II* was launched on February 17, 1959.

Less than one inch in diameter and only 1 3/8 inches in length, the Haydon Company's sub-miniature motor operates on only a tenth of a watt of power. Thirty of these motors would use no more than the same amount of power as an everyday household clock, or seven of them would require the same power as a two-cell flashlight bulb.

The parts in the orbiting satellite's adaptation of the motor are all one-half of regular dimensions. It runs with a speed of 2,500 revolutions per minute, has a permanent magnet within the rotating coils, and is equipped with ball bearings.

The A. W. Haydon engineers are certain that tooling can be obtained

promptly for production of the s
miniature motor to meet such mai
demands as may develop.

New Line of Solid State DC Amplifiers Marketed

Packard Bell Computer Corporat
has announced a new line of solid-s
DC amplifiers designed to meet
urgent need for wide-band, highly
curate amplification where reliabi
is of prime importance. This is the
available line of low-noise, comple
solid state amplifiers with transi
choppers.

Because of the rapid developm
of new weapons and numerous tes
requirements, instrumentation relia
ity is a prime factor. Normally, eq
ment can be tested only once bec
of the complexity and cost of such t

One of the basic pieces of eq
ment required to take measurem
is an amplifier. It is used to amp
signals for processing into data log

equipment for later evaluation.
major weakness in today's amplifie
the use of mechanical choppers w
tend to be unreliable and cause a
nificant failure rate.

To alleviate this condition, a
of amplifiers which use all solid-s
circuitry, including the chopper,
been designed and is now available
application in systems. With this
cal design, amplifier reliability,
system reliability, is increased at
one order of magnitude.

Wide-band differential, operati
and potentiometric amplifiers—all
izing completely solid-state circuit
are offered by Packard Bell under

xclusive arrangement with REDCOR, o meet the diversified need for a line f instrumentation amplifiers.

Differential amplifiers have many pplications in the data reduction field. Vherever a low level signal of unde- ermined reference is measured, a neans of isolating it and recovering ow amplitude signals from high noise evels is required. The low-level, wide- and, low-noise differential amplifier as been designed to meet most of hese requirements. This is the first such ifferential amplifier offering input im- edances up to 10,000 megohms, noise n the microvolt range and a common node rejection of 120 db at dc.

Operational amplifiers have many ses in data handling systems. They re used most commonly to provide mpedance matching and signal in- ersion.

Potentiometric amplifiers are pri- arily used as a buffering device to olate the source of the measurement rom the measuring device.

The three types of amplifiers des- ribed here offer bandwidths at –3 db t 200 KC. Gain accuracies, linearity nd drift figures are better than .002% n most models. The units are extreme- y small, measuring 8" by 4" by 1½", nd all have self-contained power sup- lies.

This line of completely solid-state mplifiers, for which Packard Bell Com- uter Corporation has exclusive rights, eportedly makes the amplifier one of ne most reliable pieces of equipment n the data logging field.

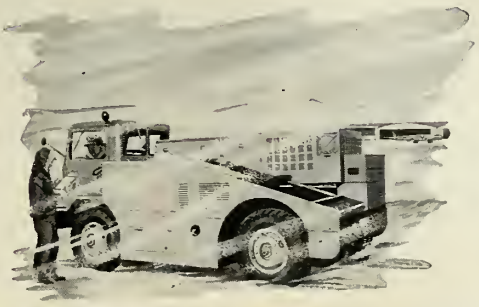
New Low-Current Thermal Relay Available

A low-current, sub-miniature ther- al relay with a firing sensitivity of nly 0.2 amps is announced by **Net- orks Electronics Corp.**



Relay is hermetically sealed by an xclusive method of bonding metal eaders to high thermal-shock resistant lass housings. The use of a transpar- nt glass case permits visual inspection f all working parts.

This tiny unit measuring only 65" dia. x .550" length, meets all

ertinent military specifications . . . perates under vibration of 20 to 2000 ps at 15 g, with a shock rating of 0 g. The temperature range extends

HEAT in military applications

HUNTER ENGINE HEATERS

starting aids for internal combustion engines

Hunter Engine Heaters, designed and manufactured in conformity with military requirements, are standard winterization gear for engines in military vehicles, hydraulic test stands, battery starting carts, generator sets, compressors, other ground support and special purpose equipment, etc. They burn any type gasoline or JP-4 fuel, with cold starts as low as –65°F. Input ranges from 30,000 to 90,000 BTU/Hour. Both uncontaminated and exhaust heat is utilized. Compact, light-weight, high capacity units, they deliver high temperature, high volume air as required for specific applications.

MODEL UH-86 This heavy-duty model has 90,000 BTU/Hr. input for delivery of high volume, high temperature air against extreme resistances to the engine, battery and lubricating oil • starts to –65°F under the most extreme conditions • used on PE-90, PE-150 and PE-200 Engines employed in ground support equipment such as C-26, MD-3A, MA-3, hydraulic test stands, battery starting carts, etc. • weighs 38 pounds, less than 27" long, 8" diameter • burns ¾ gal. fuel per hr., any grade gasoline or JP-4 fuel.

Space and personnel heaters, instant lighting torches, refrigeration and air conditioning units are other Hunter products designed for military applications.

• • •

Hunter personnel and facilities are available for all types of R & D for military heating and air conditioning.

INFORMATION

Information retrieval is a major area of study at IBM. Current investigations may lead toward such benefits as the instant accessibility to knowledge in the Library of Congress—or toward a system which can translate any of the earth's languages into English in real time.

Problems in information retrieval have defined entirely new concepts for the design of storage, input-output and "memory" units—achieving far greater capacities than any known today. These facilities will provide for the handling of the tremendous amount of updated information needed by business, science and government. With extremely rapid accessibility to vast amounts of information electronically stored, industrial and research efforts can be materially expedited. IBM needs engineers and scientists with the vision and the ability to pave the way to tomorrow.

You will enjoy unusual professional freedom and the support of a wealth of systems know-how. Comprehensive education programs are available plus the assistance of specialists of many disciplines. Working independently or as a member of a small team, your individual contributions are quickly recognized and rewarded. This is a unique opportunity for a career with a company that has an outstanding growth record.

QUALIFICATIONS

B.S., M.S., or Ph.D. in Electrical or Mechanical Engineering, Physics or Mathematics—and proven ability to assume a high degree of technical responsibility in your sphere of interest.

SOME TYPICAL ASSIGNMENTS

704 PROGRAMMER ANALYST to study data flow diagrams and write differential equations of a circuit diagram; to investigate analog and digital real-time control systems, using high-speed electronic digital and/or analog computers. Must be familiar with variable length alphabetic data, transforms, numerical analysis.

RETRIEVAL

COMPUTER OR SYSTEMS ENGINEER, MATHEMATICIAN OR PHYSICIST to design advanced computer, and work on development of new information retrieval program. Must have strong interest in transistor circuit design or in logical or systems applications of solid state circuitry.

MATHEMATICIAN to do programming of information retrieval research and plan construction of advanced systems. Will play an active part in automatic programming techniques, numerical analyses, criteria selection, probability and game theory.

SENIOR ENGINEER, MATHEMATICIAN OR PHYSICIST interested in systems; experienced in operations research, communications, missiles or radar.

For details, write, outlining background and interests, to:

INTERNATIONAL BUSINESS MACHINES CORPORATION

. . . new missile products

from −100°F to 400°F. Unit is SPST-NO, with a contact rating of 1 amp. Normally-closed operation is provided in a somewhat larger unit.

Designated Series M555, relay will handle a continuous fuse current of .120 amps max., and a firing current of .180 amps min. Fuse resistance is 15 ohms ± 15%.

The original design of this unit is based on the "fuse burnout" principle, and provides wide latitude in systems design. Manufacturer states that there has been no failure in 1,000,000 delivered units. Relay can be used as a low-current sensing device, or as overload protection in missile circuitry and other complex electronic equipment. Complete data will be sent upon request.

Circle No. 247 on Subscriber Service Card.

Micro Miniature Relay Has All Welded Construction

Contact contamination—one of the greatest problems in achieving relay reliability—has been significantly reduced by the use of all-welded construction in a new **General Electric** micro-miniature relay.

Solder flux has been one of the primary causes of relay contact contamination. The new four-pole, double-throw relay is assembled—without using solder—by an inert arc welding process which hermetically seals the header to the can.

Weighing about one ounce, the relay is rated two amperes at 26.5 volts

dc or 115 volts ac, and is dc operated using a highly efficient E-type magnet.

For application in a wide variety of equipment, including aircraft and missile electronic systems, the relay is well suited for high-temperature installations. The internal structure includes ceramic actuator and ceramic coil

spool. The relay is rated from 160 degrees C continuous ambient down to −65 degrees C.

Circuitry is symmetrical and wiring has been simplified, according to General Electric engineers. Socket mounted units may be turned end-for-end and cannot be plugged incorrectly. No polarizing pin is needed. The relay may be mounted directly on a printed circuit board or on a chassis.

Dimensions conform to standard grid patterns utilized by many electronic and component manufacturers. Terminals are on 0.2 inch centers and mounting holes are on 1.2 inch centers.

Knife edge armature bearing and other proven design features combine to yield a mechanical life of over ten million operations, according to General Electric engineers. Electrical life of the relay at rated load is in excess of 200,000 operations.

Operate and release times are six and four milliseconds respectively, including bounce. Pickup power is 400 milliwatts.

The relay withstands vibration tests to 2000 cycles per second at 30 G's and shock tests at 50 G's for 11 milliseconds.

Circle No. 248 on Subscriber Service Card.

Test Set Provides Both Swept and CW Signals

A new type of test set, which provides both swept and CW signals in a single compact instrument, is finding widespread use as a general-purpose laboratory and production-line tool.

Designated as the Model 303 Test Set by the maker, **Telonic Industries, Inc.**, the new unit contains three separate oscillators, all operating in the 20-40 mc range. Output of the three oscillator circuits is 1 volt RMS into 50 ohms. Each output is separately metered and may be attenuated from 0 to 140 db in 1 db steps, using toggle-switch attenuators.

To maintain an overall accuracy of attenuation of better than 0.5 db, hermetically sealed, deposited carbon resistors with an accuracy of 1/2% are used. A vernier attenuator covering a 0-10 db range is also provided. Extremely close control over RF radiation in the design and construction of the instrument allows accurate attenuation to output values as low as 0.1 microvolts.

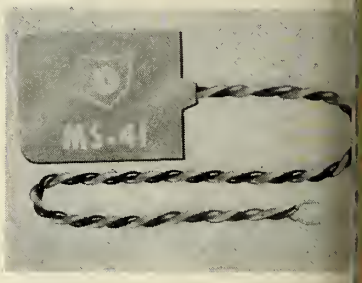
The two CW oscillators are individually tunable by dials on the instrument panel calibrated in megacycles. In addition to the megacycle markings, a 0-100 logging scale with a 10:1 vernier is provided. The tuning-knob mechanism provides a choice of 1:1 or 50:1 rotation.

The CW oscillator outputs may be used directly as test signals for the measurement of gain and similar circuit characteristics, or they may be used as extremely accurate, variable markers for the swept signals produced by the third oscillator.

The center frequency of the swept output may be turned across the full range 20 to 40 mc, and the width of the signal may be varied from 0.05 to 40% of the center frequency. At maximum sweep width the signal demonstrates a flatness of better than 0.25 db, achieved by an internal AGC circuit acting on the B+ input to the oscillator. As a result, any departure from flatness in the demodulated signal is the result of the frequency response of the circuit under test and not accountable to the original test signal.

Sweep rate of the Model 303 Test Set is line frequency, 50 or 60 cps, with the oscillator turned off during the return sweep to provide a zero base line. Source VSWR of the instrument is below 1.2:1. An external signal of approximately 0.1 volts may be used to produce a "birdy" type marker on the oscilloscope trace at any desired frequency. Telonic produces crystal-controlled markers for this purpose. Harmonic markers that produce birdies at 1.0 mc intervals across the entire band are generally included with the instrument as standard equipment.

As in all Telonic sweep generators, Model 303 markers (including the two CW outputs when used as markers) are added to the signal after it has passed through the circuit under test, thus preventing any distortion of the measured result. The "Birdy-By-Pass" marker system is an innovation developed by Telonic Industries.



The Telonic Model 303 Test Set already in use as a production-line te instrument in plants where a major m sile guidance system is now in volun production.

Magnetic-Field Sensitive Resistor Now Available

Ohio Semiconductors, Inc. a nounces the commercial availability its recently developed semiconduct device, the Magnetoresistor.

The type MS-41 Magnetoresistor a semiconductor in which the electric resistance is a function of an appli magnetic field. It features a 10 to

change in resistance with an applie field of 10 kilogauss. Greater chang can be achieved at fields greater tha 10 kilogauss with a linear dependenc At lower magnetic field densities th Magnetoresistor obeys an approxima square function. Important features the MS-41 are low noise (on the ord of Johnson noise and fast response tim The theoretical response is limited on by the relaxation time of the charg carriers. In practice the lead inductan and capacitance sets the limit.

Non-inductive design with "thinn than a dime construction."

The MS-41 Magnetoresistor is mad possible by the commercial develo ment of new compound semiconducto by Ohio Semiconductors, Inc. O. S. is a pioneer and leader in the field compound semiconductors for infr red, thermoelectric and electronic a plications.

The compound—InSb, indium ant monide, is utilized in the MS-41 Ma netoresistor. The magnitude of the ma netoresistance effect is related to th mobility of charge carriers (electron within the solid. InSb displays the hig est known electron mobilities.

Fully developed and ruggedly pac aged, the MS-41 permits the use of th magnetic gaps. It is designed to satis many different applications.

A Big Step in Digital Telemetry

Space Electronics Corp.'s DIGILOCK system offers advantages of digital techniques minus some of its disadvantages for missile system development

by Hal Gettings

WASHINGTON—A new telemetry system just off the board shows promise of answering many of the problems plaguing this most important aspect of missile development. The system, named DIGILOCK by its developer, **Space Electronics Corporation,** combines many of the advantages of digital techniques and overcomes some of its disadvantages. It offers flexibility, accuracy, and small size.

The ideal telemetering system would weigh nothing, take no space, require no bandwidth, have unlimited sophistication as to selection of data, transmission accuracy and power, and be at once 100% reliable. It would consume no power and cost nothing.

The DIGILOCK system is, of course, not the ideal. It does, however, approach the maximum communication efficiency possible under information theory, and has several features not previously available.

• **Digital systems**—Digital techniques are generally accepted for a number of reasons as being superior for communications. Primary is the inherent accuracy of a digital system. Once above the threshold, the output signal-to-noise ratio is independent of the carrier S/N; if any information is received at all, it is correct information. In analog systems, noise can vary the information modulation to cause errors in the received data.

Digital offers other advantages—in speed and capability, bandwidth, and relative signal power required. A comparison of some of these parameters has been made by L. C. Watson and M. Goldstein of **Texas Instruments** in a paper presented at the 1959 National Telemetering Conference. A summary of their comparison is shown in the table (Fig. A).

The main objection to digital telemetry has been the large amount of hardware that must be carried in the vehicle. Complicated coders and multiplexers with their attendant power supplies and accessory items not only add to space and weight but compound the reliability problem. Furthermore, existing ranges are instrumented to handle only analog (FM/FM, etc.) data; a change to digital would require extensive and expensive modification.

The first problem has been improved by development of transistorized units and advanced packaging techniques. The only complete digital (PCM) system in use today—developed by **Radiation, Inc.,** for the Holloman AFMDC rocketsled track—has an entire "airborne" package in about one cubic foot.

The answer to the second problem lies in integrating "compatible" digital units into existing analog systems, to provide the desirable features of digital along with the economies of using present equipment. The DIGILOCK makes use of these principles and requires only the addition of a decoder, sync generator, and detector to the conventional analog ground equipment. If desired, the quantized data can be stored on magnetic tape for direct entry into a digital computer.

The DIGILOCK system was developed as a result of a study made by Space Electronics Corporation under contract to **Jet Propulsion Laboratory.** This study showed that an "orthogonal" telemetering system was the most efficient, based on the bandwidth and power required per bit of information transmitted. Both analog and digital systems were compared on an analytical basis and assigned relative figures of merit. Some of the results of this comparison are shown in the graph (Fig. B).

A second part of the contract work was to design and test the most promising result of the study.

The analysis showed that for the best telemetry system a modulation subsystem must have these features:

• Good communications efficiency

Summary of Parameters for Analog and Digital Modulation

Parameter	FM/FM	PAM/FM	PDM/FM	PCM/FM
Number of Data Channels	18	18	18	18
Q	4000	4000	4000	4000
RMS Error	—	±0.5%	±0.5%	±0.4%
Output S/N Ratio	42 db	46 db	37 db	—
Video Bandwidth	80 kc	28 kc	114 kc	28 kc
RF Bandwith	440 kc	224 kc	228 kc	57.6 kc
Deviation Ratio	1.5	1.1	0.6	0.6
Carrier Deviation	125 kc	31 kc	69 kc	16.8 kc
Threshold S/N Ratio	9 db	9 db	9 db	9 db
$\frac{S_p}{K}$ = Relative Required Signal Power x 10^{-3}	3450	1760	1790	453
$\frac{\left(\frac{S_p}{K}\right)\text{ db}}{\left(\frac{S_p}{K}\right)\text{ db (PCM)}}$	8.8 db	5.9 db	6.0 db	0 db

FIG. A—Digital systems provide speed and capability, bandwidth and signal power.

nearing the limit of efficiency . . .

- Variable data rate
- Variable accuracy
- Digital data transmission

• **Orthogonal systems**—The development of the DIGILOCK, undertaken to meet these requirements, was described in a paper by A. W. Newberry at the Semiannual meeting of the American Rocket Society in June. Newberry said the family of orthogonal systems closely approaches the theoretical limit of communication efficiency, as illustrated in the graph.

An "orthogonal" system is defined as one for which N messages can be transmitted, each of which consists of N degrees of freedom. Encoded messages are all equally different or equally spaced in an N dimensional space. The system possesses N matched filters at the receiver, one for each possible transmitted signal.

The signals and corresponding matched filters are chosen so that the outputs from all but one matched filter are zero after the signal is received.

• **Desired characteristics**—It has long been considered desirable in telemetry design to make a system as sophisticated, or "intelligent," as possible consistent with weight and space requirements. Ideally, a system would be able to choose only pertinent information and transmit it at selected times, thus saving considerably in bandwidth and power. The complexity of such an intelligent system, however, has precluded its use up until this time.

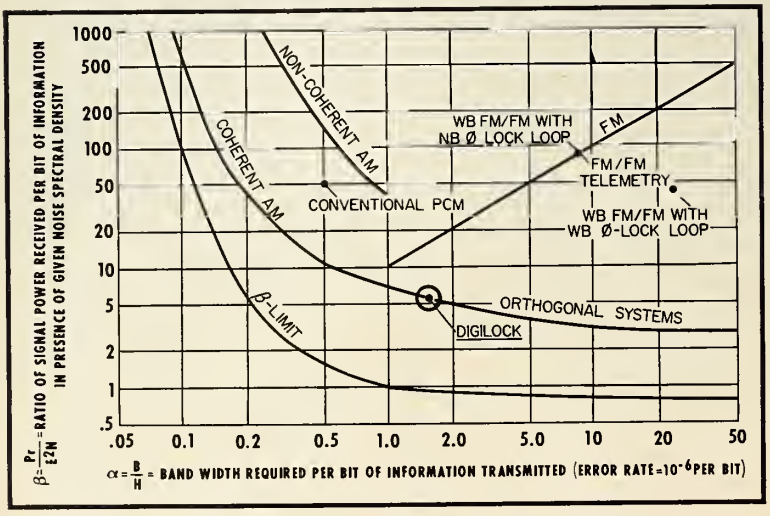

FIG. B—Comparison of the communication efficiency of various systems.

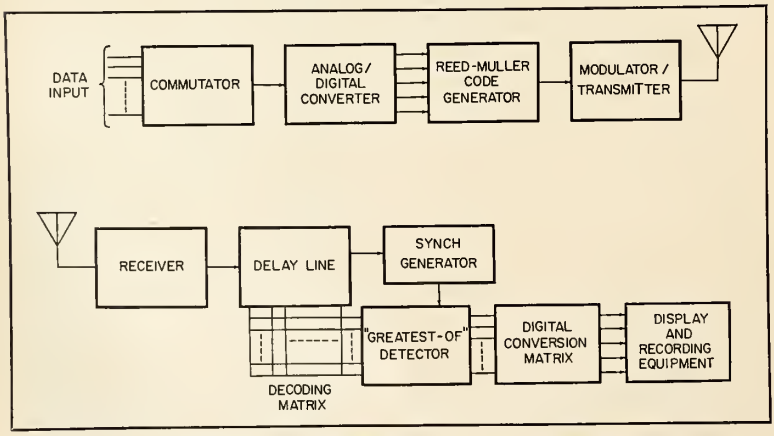

FIG. C—A block diagram of the workings of the DIGILOCK pulse code system.

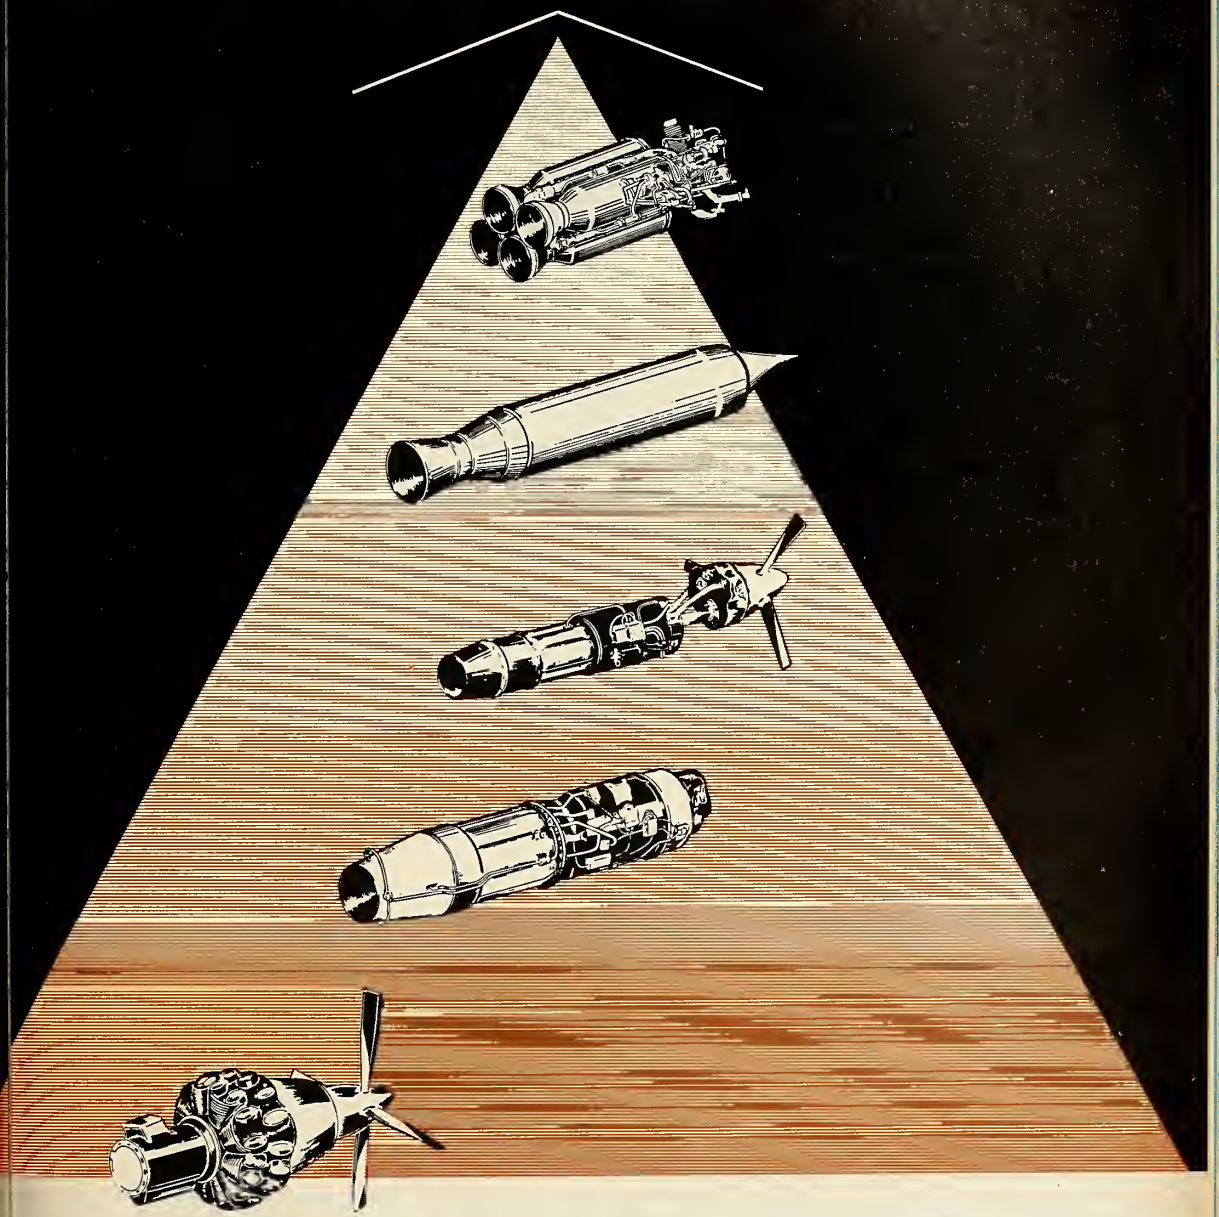
To this end, the DIGILOCK equ ment has incorporated both varial accuracy and variable data rate. The features offer considerable economy a provide a more intelligent system.

In the first place, it is very in ficient to transmit information wi precision beyond the meaning of t data. It would be wasteful, for instanc to transmit continuous precise da when simple presence-absence or even per-unit-time information would sufficient. The available information b could better be reserved for measur ments where greater precision is r quired.

Variable data rate offers, primaril power economy. An example would a system alternately turned on and o When on, the data rate is some nomin maximum; when off, the rate is zer By controlling the on-off time, the e fective data rate can be varied over wide range. If the meaningful data properly encoded and stored, a wort while saving in power is provided.

But intermittent operation does n provide all of the desirable feature without some additional change, t maximum communication range r mains a fixed function of transmitt power, transmission bandwidth, and e fective ground station sensitivity. T possibility of variable transmissio bandwidth is a feature inherent DIGILOCK and offers greater a vantages. Variable transmission ban width can result in the adjustment data rate to match a specific missio requirement. Even more important, a justment can be made during a tran interval, allowing the decrease of da rate with increasing communicatio range—thereby making possible operating link at distances otherwi impossible.



• **DIGILOCK operation**—DIG LOCK is a pulse code (PCM) syste and, therefore, a time-division mult plex system. Primary operation co sists of sampling an input data sourc quantizing the data sample, transm ting a coded representation of t quantized data sample, receiving ar decoding the data, and either storin or displaying a measure of the info mation received (Fig. C).

In an orthogonal system, messag must be encoded so that they are equally different or equally space Also, each message must be recognize by its own matched filter. The matche filter decoder is therefore the heart the system and its operation must l understood if the operation of t complete system is to be understood

• **Delay line**—The principal el ment in the matched filter decoder a multiple-tapped magnetostriction d lay line, which provides a means storing many bits of information r

CONTROLS

FOR THE FULL SPECTRUM OF PROPULSION SYSTEMS

Bendix* has long been a leader in supplying controls and fuel systems for all types of aircraft engines. Today, Bendix is proving to be a natural for new challenges in related missile fields—on ram jets, rockets, nuclear power, and other advanced propulsion systems. So, when it comes to controls, remember that Bendix has the background—and is anxious to share it in solving your problems. *REG. U.S. PAT. OFF.

BENDIX PRODUCTS DIVISION **SOUTH BEND, IND.**

Bendix AVIATION CORPORATION

Circle No. 12 on Subscriber Service Card.

ceived in time sequence, yet allows continuous nondestructive readout of information stored on the line so that a succession of events or a succession of bits of information can be simultaneously compared.

The line used in the DIGILOCK decoder has a nickel alloy ribbon as its magnetostrictive material. It has a characteristic propagation velocity of approximately five microseconds per inch, exhibits a linear input/output characteristic over approximately a 40 db range, and has a half-power bandwidth of approximately 400 kc centered at 500 kc. Typical lines are several feet in length and pickoffs or taps can be positioned several to the inch if desired. This element, therefore, provides a convenient means of correlating events separated in time by intervals up to several hundred microseconds.

• **Summing matrix**—A summing matrix associated with a set of systematically located taps can "recognize" a discrete pattern of pulses or otherwise coded information bits. Moreover, a large number of summing matrices properly "matched" with coded messages can individually recognize a large number of multiple-digit code transmissions. Hence, the magnetostriction delay line is a very versatile element for this application; it leads to variable data rate because if the pulse code transmission is "slowed down," this simply means adjusting the taps to be farther apart. It provides an extremely important characteristic common to most correlation detection systems—that of summing systematic events while tending to cancel random events.

This last effect is obviously of primary significance because a cancellation or decrease of random noise means a lower system threshold and, consequently, a greater communication range with a given amount of transmitter power.

• **Detector**—The best detector to use with a matched filter decoder is one that simultaneously compares all outputs and determines which filter output is greatest. This approach has been mechanized in the DIGILOCK system by connecting each filter output to a transistor operated in the emitter-follower configuration with all emitters tied to one common resistor. The transistor realizing the "greatest" signal at its input is turned on, developing a voltage across the common resistor which in turn causes all other transistors to be back-biased with resultant low conduction on all but the one "greatest-of" output bus.

TO OBTAIN CODE FOR ANY 5-BIT DATA POINT, ADD APPROPRIATE CODES (BINARY ADDITION)

FIG. D—Summary binary scaler outputs.

After detection, the information can be directed to a conventional decommutator and analog display system, or it can be identified and stored as quantized information on magnetic tape in a format compatible with a digital computer.

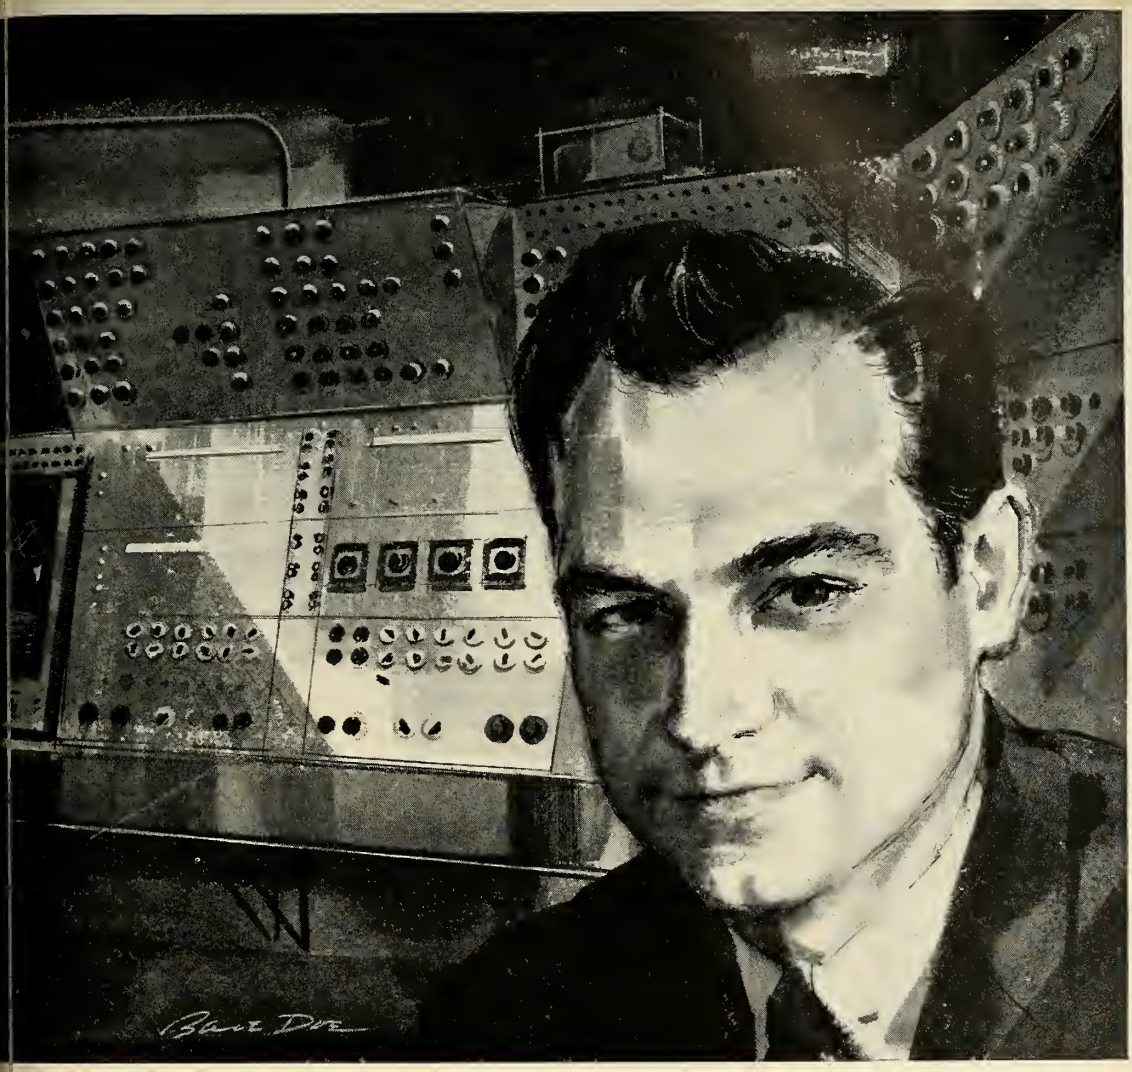
• **Encoder**—The function of the encoder is simply to determine which of the codes from the set representing all possible data values best represents the value of a data sample—and to cause this particular code to be transmitted. The particular code group chosen for use with the DIGILOCK system is a "maximum redundancy Reed-Muller" group which, for this system, consists of 32 different codes, each 16 digits long.

This code set has orthogonal properties and can be formed by systematically summing the outputs of a binary scaler as shown in the table (Fig. D). Quantization to 32 levels must be accomplished by the analog-to-digital converter, which establishes a discrete set of commands controlling the generation of the code corresponding to the level established in the quantization process.

The 32-level quantization implies that each data sample contains five bits of information and that this information can be encoded in a 5-digit binary code. A simple binary code, however, does not possess orthogonal characteristics. The 16-digit code can be detected at a lower signal threshold than could the 5-digit code, even though both might be allotted equal transmission power and the 16-digit code would require 16/5 the bandwidth of the 5-digit code. This is an example of increased efficiency resulting from bandwidth expansion techniques.

• **Timing and rate control**—A timing and data rate control system, consisting of a crystal oscillator and a binary scaler of several stages, allows the timing system to be "slowed down" by factors of two simply by positio one switch. The analog-to-digital c verter uses a "stairstep" voltage ge ator and a comparator amplifier.

In operation, the timing system s a 5-stage binary scaler through 32 j sible states while a stairstep voltag being generated. When the compar amplifier indicates that the stair voltage first exceeds a data sample, inhibit signal stops the scaler, sto a binary measure of the data sam The specific on-or-off state of the st of the binary scaler is used as c mand information to simple digital l in the form of AND gates and CLUSIVE OR circuitry to generate one desired of the 32 possible co which can be formed by the bi addition of outputs from binary sc stages.



In operation, the system will use storage registers in the analog-to-dig conversion system; one will control code generator to transmit a code re senting a data sample quantized in preceding period while the second re ter is in process of storing a new q tized value. At the end of each w simple logic reverses the function the two storage registers. This appro results in nearly a 100% duty cycl transmitted information.

• **Synchronization**—System op tion depends of course on proper chronization of the decoder with airborne encoder. This is accomplis by a special code transmitted at s matic intervals, recognized by matched filter and detector and in a phase-locked flywheel sync sys to generate a gate signal. This si enables the "greatest-of" detector ing a short period surrounding match interval for each code t mitted.

• **Prototype evaluation**—First n surements of DIGILOCK operation portedly showed results within 3 dl that predicted. Several elements of system are not entirely new—in they are commercially available. means that application of the syste early missions would not require c plete replacement of all components for example, a world-wide ground tion network.

The airborne system particul lends itself to simple transistorized cuitry and extremely low opera power requirements. The complete borne system weight, excluding transmitter, is about 5 pounds.

Study of the system as designe dicates that maximum data rates such that one DIGILOCK system provide information bandwidth eq lent, for example, to several ty FM/FM systems and, therefore, be of extreme value in near-future missile system development progra

C. L. Hampton

Computer expert Chuck Hampton is a man with problems. As head of our Avionics Division's Computer Applications section, Hampton pits his analog and digital computers against the mathematical intricacies of infrared research, optics, spectral background studies, feedback control, and weapon system design.

At thirty, with a BSEE from the University of Illinois, Chuck Hampton is a Senior Engineer. He typifies the progress made at Aerojet by younger men of technical distinction, in electronics and many other areas.

We think the challenge is imposing, the opportunity impressive. May we see *your* resume? AEROJET-GENERAL CORPORATION, Box 296J, Azusa, California or Box 1947J, Sacramento, California. Attn: Director of Scientific and Engineering Personnel.

Circle No. 13 on Subscriber Service Card.

RAUTH

J. Donald Rauth, 41-year-old general manager of The Martin Co.'s Nuclear Division, was elected vice president of the company, retaining his post as general manager of Martin-Nuclear. Rauth, who joined Martin in 1940 as a draftsman, served in turn as a group engineer, project engineer on the *Gorgon IV* drone program, assistant chief project engineer for the company, and as manager of the Engineering Projects Division. He holds several patents for engineering inventions.

The Marquardt Corp. has established a Marketing Div. and Administration Div. in its Power Systems Group. **Paul J. Papanek** has been appointed director of Marketing and **Richard A. Davis,** director of Administration.

The two new divisions join the other three that make up the Power Systems Group at Van Nuys plant—Propulsion, Controls and Accessories, and Test. Customer Relations, Contract Administration, Marketing Planning, Proposals and Publications fall under the New Marketing Div.

In other personnel changes, **L. E. Dunn,** former chief engineer, has been appointed Test Division director; **R. K. Wead** replaces Papanek as manager-Customer Relations; and **F. M. DeLaval** has been named manager-Marketing Planning.

The new divisions are part of a long-range organizational realignment which began in January.

BEAGLES

Robert Beagles has joined Packard Bell Electronics Corp. as chief engineer-advanced development, Technical Products Div. Beagles has been associated with RCA, Bendix and North American Aviation during the past 18 years in radar and missile electronics. He comes to Packard Bell after six years with RCA, where he was responsible for systems engineering activities in airborne radar, electronic warfare, and airborne communications and navigation.

Coleman Engineering Co., Inc., has formed a wholly owned subsidiary, Coleman Electronics, Inc., to manufacture the company's "Digitizer" and related automatic data handling and control systems. **T. E. Coalson** has been elected vice president and will serve as general manager of the new subsidiary. **T. C. Coleman** will act as president of both companies. Coleman has also promoted **C. A. Brosterhous** to chief engineer and named **R. D. Farnham,** former Eastern manager of the company, director of Customer Relations.

James R. Black has been appointed manager of the Microelectronics Laboratory in the Solid State Electronics Department of Motorola's Military Electronics Division. Formerly an associate professor in Electrical Engineering at the University of Michigan, Black will be responsible for research and development in microelectronics and applications to microminiaturized and integrated function circuitry.

William D. Caffin is contract administrator for the Electromechanical Division of Bowmar Instrument Corp. He was formerly assistant sales manager of Daystrom Transicoil Div., where he served in management and engineering capacities.

CAMPBELL

Transval Electronics Corp. has appointed **Jack Campbell** director of government contracts. The appointment reflects the broadening scope of the company's activities in past months in the field of missile, aircraft and drone electronics. Campbell came to Transval from Hayes Aircraft, Birmingham, Ala., where he was project engineer on the C-119 program.

James O. Seamans, new *Sparrow III* program manager for the Missile Systems Division of Raytheon Co., was formerly *Sparrow III* technical director at the Bedford Laboratories, where engineering of the weapon is carried on. Seamans joined Raytheon in 1951 as senior engineer responsible for flight testing after leaving the Western Electric Co. in Winston-Salem.

George S. Schairer was elected vice president for research and development at Boeing Airplane Co.

VLCEK

Adolph Vlcek, Jr., has been named director of manufacturing at Martin's Baltimore Division, succeeding **Vernon R. Rawlings,** general manager of Martin's newly created Activation Division. Vlcek joined Martin as a metal bench helper in 1930 at the age of 16 and worked his way up to Quality Control manager, tooling manager, and Manufacturing, Engineering and Research manager before promotion to his new position.

Benjamin O. Delaney has been na to the new position of assistant man for Missile Operations under the Techr Operations Manager at Vitro Laborato Silver Spring, Md. Delaney, form head of the Missile Projects departm held several engineering positions served with the rank of commander in U.S. Navy prior to joining Vitro in 1

SWINDELLS

Dr. Frank E. Swindells has been moted to man of research for p tosensitive dev and chemical search for the E tronic Tube Divi of Allen B. Mont Laborato Inc. He was merly manager chemical resea with emphasis transparent and black background sc phosphors, after coming to Du M from the Photo Products Dept. of E Du Pont de Nemours & Co.

Leang P. Yeh, telecommunications gineer specializing in communications missiles, satellites and space vehicles, joined Page Communications Engine Inc., as consultant to the vice presi and director of Engineering. Yeh also serve as technical advisor on Pa international projects now underway Libya, Greenland, Iceland, England, the Pacific Ocean area. Before joi Page, Yeh was with the General Ele Co., and previously spent three years Westinghouse Electric Corp.

John C. Pitchford, recently ret from the Air Force as a colonel, has b named project manager at Benson-Le Corporation, Los Angeles manufact of data processing equipment. He study future developments of the c pany's standard product line. Pitchfo last service assignment was Project Of for the deployment of IRBM's to NA

John B. Rittenhouse, Research Gr Supervisor in Chemistry at California stitute of Technology's Jet Propul Laboratory, was named recipient of award by the American Society for T ing Materials for a paper he wrote on chemical effects of certain acids on m used in rockets.

Monogram Precision Industries, has named **Victor Gehrig** and **Robert Lehman** senior vice presidents. USAF Eyes *AA-5103*

An air-to-ground version of **Nord Aviation's** AA-5103, a two-stage solid-fueled missile controlled by radio link along its entire flight path, is reported under evaluation by USAF.

Nord Aviation has just made a deal with **Bolkow-Entwicklingen** of Germany to manufacture the air-to-air version of the 295-pound missile.

Astrodyne Control Shifts

North American Aviation is acquiring full ownership of **Astrodyne, Inc.,** McGregor, Tex., which it founded jointly with **Phillips Petroleum Co.,** in February, 1958, to produce, research and develop high-energy rocket fuels. Terms were not disclosed.

NASA's Novel Rocket

SIX-STAGE ROCKET designed by the National Aeronautics and Space Administration to test re-entry friction. Unlike other rockets, the stages are phased 1, 2, 3, 6, 5 and 4. The first three boosters send the vehicle up to about 200 miles, while the last three send the vehicle hurtling towards earth at 16,000 m.p.h. The re-entry trail—to the point where the final stage is consumed by friction with the air—is followed by radars and radio receivers.

Expanding the Frontiers of Space Technology in

GUIDANCE

■ As systems manager for such major projects as the Navy POLARIS FBM; DISCOVERER Satellite; Army KINGFISHER; Air Force Q-5, X-7 and X-17; Lockheed Missiles and Space Division is deeply involved in improving existing guidance systems and designing solutions to new problems.

ENGINEERS AND SCIENTISTS

The Division's projects and research and development programs reach far into the future and deal with unknown and stimulating environments. It is a rewarding future with a company that has an outstanding record of progress and achievement. There are inertial guidance positions now available at various Lockheed facilities and a particular need at our Vandenberg AFB location. If you are experienced in guidance work in one or more of the following areas, or in related fields, we invite your inquiry: circuit design; hydraulics; dynamic analysis; servo systems analysis and design; transistor circuit design or analog computer simulation.

Write: Research and Development Staff, Dept. G2-29, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship required.

Heat and mass transfer . . .

as they apply to missiles and aircraft are thoroughly covered in a new Air Force bibliography available from the Commerce Department's Office of Technical Services. The 172-page book is not only a bibliography of work in heat transfer and mass transfer, but also a volume of abstracts dealing with specific problems. W. J. Christian and T. H. Schiffman, Illinois Institute of Technology, compiled the volume for Wright Air Development Center. They split the volume into three parts: Local and average mass transfer from surfaces under isothermal and non-isothermal conditions; local and average heat transfer from pertinent airfoil surfaces; and correlations between heat and mass transfer. It's available from OTS at $3.00. (Order PB 151517.)

Low humidity storage containers . . .

can substitute for some types of dehumidified warehouse storage, says an Army Ordnance research team. Sprayable, strippable plastic containers in which it's possible to maintain low humidity statically or dynamically are reviewed in another Commerce Department, OTS, publication—"Standardization Study of Long-Term Storage Process: Strippable Film Containers," by W. J. Shields and W. F. McTeague, Frankford Arsenal. The 20-page study concludes that the plastic containers "are suitable substitutes for dehumidified warehouse storage of assembled, irregularly shaped material." Essentially, they are simply coatings sprayed on material requiring storage. Advantages: low cost of fabrication and maintenance, mobility of stored wheeled items, light weight, ease of removal.

Storage, without warehouse, up to two years . . .

is possible with the coatings. Storage of more than 10 years is possible with top coatings of mastic, or with mastic and aluminized paint. The report compares adhering and nonadhering film materials and discusses maintenance requirements, cost, and durability of one to three coats. Some industry people have been thinking about these coatings in terms of solid propellants. The report is available from OTS at 75 cents (order PB 151295.).

Astrodyne's insulation . . .

for solid-propellant motors may soon find some non-missile civilian uses. At least that's the hope of **Astrodyne** officials who say one firm already is interested. Astrodyne will not name the firm, its field of operations, or its possible use for the rubber and asbestos material described in this column July 6. Officials say that in the meantime prospective users of the material probably still have to be defense contractors, but "the situation hasn't come up yet." The insulation itself is not actually classified, but Astrodyne and the Navy are guarding details of its composition. Possible civilian uses—Astrodyne will neither confirm nor deny any of these—include insulation for high-temperature reacting vessels or combustion chambers; packaging; railroad refrigerator car and reefer truck liners.

Beryllium patent is available . . .

for public use. Patent number 2,872,363 has been released by the Atomic Energy Commission. It is for a "Method of Working Beryllium." A beryllium billet is sheathed with a jacket of copper or stainless steel. It can then be worked by drawing or similar means at 570°F to 750°F. Another patent just released by AEC (No. 2,872,310) is for producing a binary zirconium antimony alloy which is extremely hard and corrosion-resistant.

ls' 'Zoonik' Launching uses Calm Speculation

Vashington—Russia's announced e launching of two dogs and a it has raised more speculation than an.

Radio Moscow began excitedly and atedly to announce the launching he "zoonik" July 6—four days t it took place.

The Russians said the dogs—Otnaya and Snezhinka—and an unified rabbit were boosted to a at height" by an IRBM and successfully returned to earth.

The payload weighed more than 0 pounds. The Russians said it was

HSE dogs, shown training in rocket , may have taken latest flight.

heaviest ever hurled into space. e M/R Oct. 20, 1958)

No figures were released on how g the dogs and rabbit traveled.

The Russians said the launching ked Otvazhnaya's third trip into e. It came six weeks after the y launched Monkeys Able and r in the nose of a *Jupiter* and successfully recovered them more than 50 miles down the Atlantic Missile ge.

The Russians said instruments rd the dog and rabbit flight telered information on the ionosphere, treams and the ultraviolet part of solar spectrum.

The Russians attempted to make nost of the launching. Radio Mosov interrupted a broadcast of a footal match to announce the four-day news. The bulletin then was anced repeatedly and Soviet academians hailed the event as "another iph of Soviet science."

Soviet commentators declared that missile that launched the "zoonik" the most powerful single-stage booster ever launched to date. They said it was "much stronger than anything the Americans have."

However, the Russian boasts brought little of the alarm previously produced by Soviet space feats.

Despite the Soviet boasts of paving the way for space flight, the "zoonik" was nothing particularly new. Russia has announced repeated launching and recovery of dogs. The United States has recovered two monkeys.

Moreover, the announcement followed more than six months of Russian silence. Not since the sensational launching of *Lunik* have they indicated activity in space exploration. And U.S. scientists have been expecting the worst—an announcement that Russia has put a man into orbit.

The reaction is speculation as to whether Russia's space program may —for some unknown reason—have slipped.

Missile Designed for Firefighting

San Diego—**Solar Aircraft Company** has devised a new guided missile fire fighter that is launched like a rocket and hovers like a helicopter.

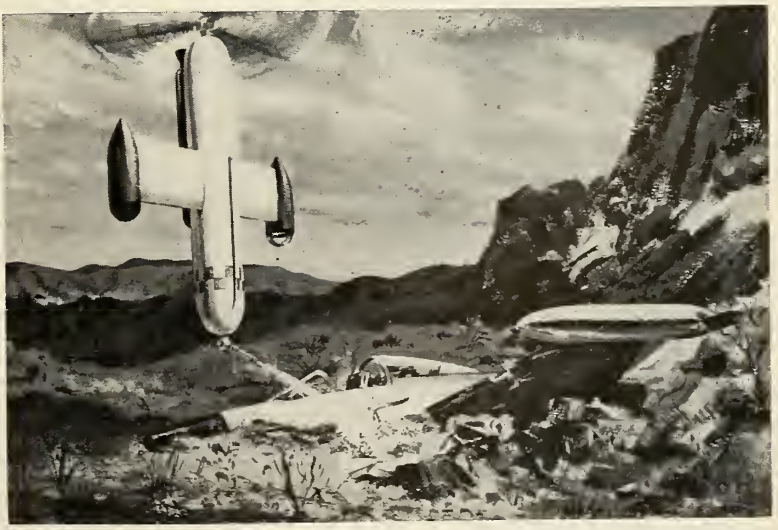
Conceived by Solar engineers, and dubbed the *"Firefly,"* it will reportedly fly anywhere within five miles in 40 seconds, just a fraction of the time required by conventional firefighting equipment. It is fired and guided by push buttons to its destination. an air crash or other site of potential fire.

After reaching a crash scene, the unmanned craft turns into a helicopter and hovers over the area. The remote operator can then flip a switch releasing more than a ton of extinguishing liquid over the danger area.

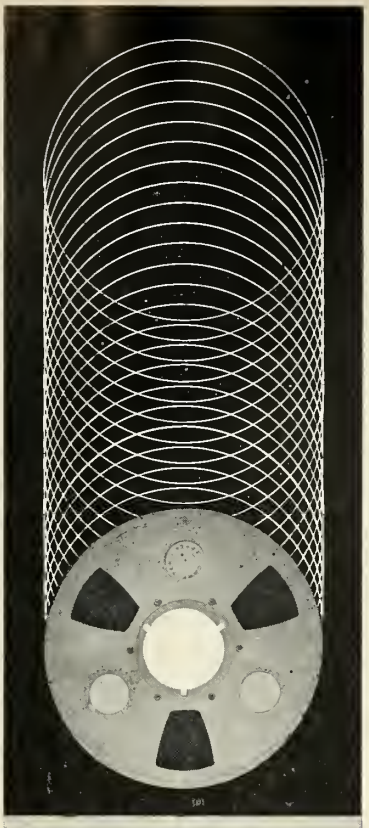
According to Solar engineers, the *Firefly* does not require any new technology, but can be built by perfecting existing systems.

With helicopter blades in its tail and a fire nozzle in its nose, the *Firefly* looks like a small jet aircraft. A solid propellant rocket under the fuselage shoots the missile into cruise altitude. When in flight, Solar reports, the bird operates as a fixed wing aircraft.

The three rotor blades are locked back to serve as tail surfaces. It is transformed into a helicopter by unlocking its rotors and firing up small rocket motors in each rotor blade tip.



Solar engineers report that the missile-helicopter reaches its goal in three flight stages: 1) a ballistic trajectory, 2) powered level flight and glide and 3) deceleration and hovering.



The bird picks up commands from a remote operator through an electronic "brain," and translates these into mechanical control of its devices. Radar and electronic sensing devices in the vehicle enable the operator to discover where and how severe a fire is and where and how much fire extinguishing fluid to release.

Mounted on a launcher which has a quick-opening metal-ribbed plastic housing for protection against inclement weather, the *Firefly* would be placed opposite a control tower near landing strips of an airfield.

Ground controls, consisting of a console and radar panel, would be located in the airfield's control tower. The radar can be tied in with equipment already present at most military and commercial airfields, Solar says.

The *Firefly's* body, exclusive of rotors and dispensing nozzle, is some 16 feet long, and its wing span is about the same. It weighs about 5000 pounds, including its payload of extinguishing fluid.

AMPEX PRECISION REELS:

Maximum Security with Minimum Clearances

Ever have trouble with the edge-track data on your magnetic tape? Possibly an Ampex Precision Reel could have prevented the difficulty. How? The secret is in the metal. Only Ampex makes precision reels of magnesium. It gives you thick, rigid, nontapered flanges that protect the tape. A strong hub, too, that doesn't distort under pack pressure. And because magnesium is light, Ampex achieves this extra strength within the weight limits your recorder is accustomed to. All this, together with a calculated design that means minimum clearances and tolerances, gives you a better tape pack—pass after pass. The security of Ampex Precision Reels is available in all conventional recording sizes.

west coast industry . . .

By FRED S. HUNTER

Someone said recently, "You can't fire unemployment statistics at the Russians." This seems to us to be a reasonably sagacious observation on the political byplay going on between the congressional delegations from New York and California over the distribution of defense contracts. There's no argument about California having a disproportionate share of present defense contracts. But there's also no argument about California having the research capabilities, the test centers, the manufacturing facilities, the trained personnel and the overall know-how to do the weapons job. You can't change these factors by legislation.

Keeping factory doors open in a phase . . .

of defense procurement which the various military services have to take into consideration. You'll recall the hue and cry that went up in California when the Air Force cancelled out the *Navaho* intercontinental missile and **North American Aviation** promptly began laying off employees. Then, a little later, North American picked up two juicy contracts, one for the F-108 and the other for the B-70, and a lot of people were surprised because the B-70 contract didn't go to **Boeing,** the Strategic Air Command's specialist in big bombers. So what happened? Boeing became a partner for development and assembly of the wing and is in the B-70 program in a big way.

Invitations to submit proposals for the missile . . .

carrier for the *Eagle* project have been issued by the Navy to several of its experienced prime contractors, such as **Chance-Vought, Douglas-El Segundo, Grumman, McDonnell** and **North American-Columbus.** We'll venture a prediction that the manufacturer capturing this plum will be Chance Vought. Our reasoning takes into consideration the cancellation of the *Regulus II* and the F8U-3. We're assuming, of course, that there will be little to choose between designs submitted and that all will meet requirements.

First blasts from the *X-15*'s rocket engines . . .

will be echoing in the upper altitudes over Utah and Nevada by the end of this month or early in August with the first powered flight of the research craft. Of comparable significance is the fact that the No. 3 aircraft has been turned over to the flight test group, completely finished as far as manufacturing is concerned. This is the vehicle in which the big 60,000-pound-thrust engine being specially developed by **Thiokol's Reaction Motors Division** will be installed first. Later on, the No. 1 and No. 2 planes will be retrofitted. North American has a group test engine at Edwards Air Force Base now and is scheduled to get a flight engine before long.

Research activities keep right on . . .

becoming more diverse and complex in the missiles and rockets industry. **North American's Rocketdyne Division** recently found it advisable to reorganize its research department into two groups, one a physical sciences section, the other an engineering sciences section. Under physical sciences come physics and mathematics, combustion and heat transfer, electrical propulsion and a chemical group comprising theoretical chemistry and chemical engineering. Under engineering sciences come propulsion devices and systems, experimental instrumentation, research design and a special-products group made up of igniters and special devices, igniter fabrication and solid propellant process development.

Peter Masefield, Bristol Aircraft managing director . . .

evoked an appreciative laugh at the recent IAS session with this observation: "The principal function of an advanced design department nowadays is to keep up with the public relations department."

NAVY

6,000—Newport News Shipbuilding and dock Co., Newport News, Va., for con-ıction of two nuclear-powered subma-es that will carry *Polaris* missiles.

1,541—Electric Boat Div., General Dy-nics Corp., N.Y., for construction of a lear-powered submarine that will y *Polaris* missiles.

01—Hazeltine Electronics Div., Hazel-Corp., Little Neck, L.I., N.Y., for gn, development, testing and produc-of one intercept tracking and con-group AN/SPA-43.

00—Massachusetts Institute of Tech-gy, Cambridge, for conducting a feasi-ty study encompassing those aspects fundamental and applied research re-ed for the evaluation of a high-speed puter system.

16—Heintz Div., Keisey Hayes Co., adelphia, for FFAR rocket head.

47—American Machine & Foundry Co., falo, for warhead, MK37-0.

86—Raytheon Manufacturing Co., Wal-n, Mass., for investigation of methods improving the operation of cross-field ntrant beam devices.

0—North American Aviation, Inc., Mis-Division, Downey, Calif., for conduct-an engineering study of the applica-of sandwich and/or other light-ght structural design and/or combina-thereof, to the hydrofoil and strut ion of Sketch PD 4374. Titanium skins l be used.

7—Philco Corp., Philadelphia, for vari-type oscilloscopes.

0—Cooke Engineering Co., San Mateo, f., for assembly and check-out of mo-missile tracking units.

0—Whirlpool Corp., Saint Joseph, n., for developing, testing and furnish-five Type I thermoelectric tempera-ture-controlled chambers including con-trol circuitry and power supplies.

$39,085—Sperry Rand Corp., Sperry Gyro-scope Co., Div., Sunnyvale, Calif., for re-search and development of missile-aircraft interference study.

$36,004—Nuclear Electronics Corp., Philadel-phia, for radiac computer-indicator (Scaler) CP-297.

AIR FORCE

$6,000,000—Avco Corp., Lycoming Div., Strat-ford, Conn., for production of missile rocket chambers for second- and third-stage chambers of "second generation" *Minuteman* ICBM.

$2,000,000—Westinghouse Electric Corp., for manufacture of experimental "hardware" for infrared, reconnaissance, communica-tions, telemetry, flight control and other military applications, using molecules as building blocks.

$1,500,000—Telecomputing Corporation, Los Angeles, for the manufacture of spare valve components.

$810,000—Massachusetts Institute of Tech-nology, Dept. of Aeronautical Engineering, Instrumentation Laboratory, Cambridge, for study, design, fabrication and test of advanced inertial navigation system.

$800,000—The W. L. Maxon Corporation, N.Y., for fabrication and testing of a fly-able model of the AN/APS-99 (XY-1) radar.

$796,664—Thiokoi Chemical Corp., Utah Div., Brigham City, for 88 M-16E-1 rocket en-gines for the *Mace* missile.

$500,000—American Electronics, Inc., Los Angeles, for design and manufacture of tactical ground support equipment for the B-58 "Hustler" jet bomber program (subcontract from Convair Div. General Dynamics Corp.).

$439,986—Aeronautical & Instrument Div., Robertshaw-Fulton Controls Co., Ana-heim, Calif., for helium pressure regula-tors for use on the *Titan* ICBM (subcon-tract from The Martin Co., Denver).

$331,416—Sperry Rand Corp., Sperry Gyro-scope Co., Div., Great Neck, L.I., N.Y., for microwave command guidance system op-eration and support.

$192,000—Sperry Rand Corp., Sperry Phoenix Co., Div., Phoenix, Ariz., for guidance data transponder set.

$191,227—Motoroia, Inc., Chicago Military Electronics Center, for electron tubes.

$159,940—Wentworth Institute, Boston, for research directed toward physical and chemical properties of the upper atmos-phere.

$90,000—Stanford University, Stanford, Calif., for continuation of research on "Micro-wave Solar Radiation."

$50,301—Eitel-McCullough, Inc., San Carlos, Calif., for various electron tubes.

$42,079—Litton Industries of California, Beverly Hills, for continuation of research on "Electromagnetic Acceleration of Gas Plasmas."

$38,574—University of Illinois, Urbana, for investigation of the use of internal fric-tion techniques in the study of diffusion and phase changes in metals.

$35,000—The Catholic University of America, Washington, D.C., for continuation of re-search on "Studies of Molecular Physics."

$30,000—University of Western Ontario, Lon-don, Canada, for research on gas scintil-lations from ionizing radiations.

$28,980—Mass. Institute of Technology, Cambridge, for continuation of research on "Fracture under Plastic Flow."

ARMY

$60,159,214—Western Electric Co., N.Y., for work on the *Nike-Hercules* system, includ-ing missiles, ground equipment, repair parts, engineering services and improve-ments on the system (five contracts).

BARCO

Flexible Joints for Handling Liquid Oxygen and other missile fuels

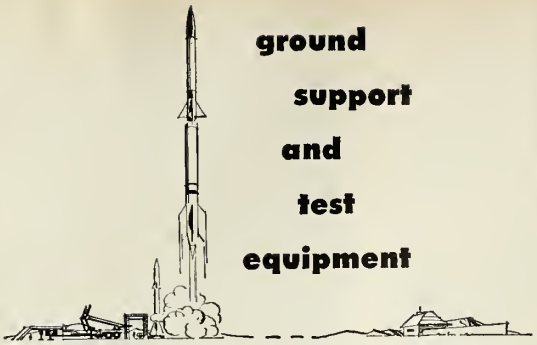
BARCO has the *specially designed* flexible joint which has passed the official "Qualification Test":

—Used in piping on fueling lines handling liquid oxygen, JP4 and JP5 fuel, white and red fuming nitric ocid, and other chemicals.

—Provides swivel motion to ollow for thermol exponsian ond contraction.

—High corrosion resistonce. Other speciol designs availoble. For temperotures from −320°F. to +1,000°F., ond higher. Also joints for gas and hydraulic service.

Potent Pending



(Right) 6"—180° Flonged Barca Flexible Joint for use in fueling line handling liquid propellont. Also straight ond 90° designs.

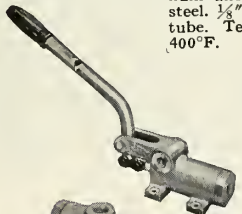
ground support and test equipment

REPUBLIC VALVES



FREE-FLOW CHECK VALVES

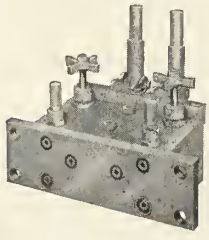
No leakage. 3000 psi. Very low pressure drop. Can be furnished to open at ¼ to 35 psi. Brass, stainless steel, or aluminum alloy. ⅛" to 2" pipe or tube. Temp. range -65° to 200°F.

RELIEF VALVES

Quick unloading, smooth operation. Guided shut-off piston with stainless steel or Nylon seat. Pressure range to 4000 psi. Brass, aluminum alloy, or stainless steel. ⅛" to ¾" pipe or tube. Temp. range to 400°F.

HAND PUMP

For hydraulic applications on missile carrier and support equipment. Double-acting. 2 cu. in. displacement per cycle. 1000 psi. working pressure. Aluminum alloy body, stainless steel trim. -65° to 160°F.



LEVELATOR VALVE

For automatically maintaining height and level condition in any vehicle with air spring suspension. Controls swaying in transit, and off-level position while standing. Applicable to trucks, buses, trailers, carriers, cranes, etc.

LO-TORQ SELECTOR VALVES

Smooth, easy operation, with low turning torque because of pressure balancing design. 0 to 6000 psi. Bronze, steel, or aluminum alloy. ⅛" to 2" pipe or tube. 2, 3, 4 ports.

DUAL HAND PUMP

2 pumps, 2 relief valves, and 2 needle shut-off valves, compactly manifolded for elevating mechanisms, hydraulic applications on ground support equipment, etc. Aluminum alloy body, stainless steel trim. -65° to 160°F.

contracts

$13,235,000—**Food Machinery & Chemical Corp.**, N.Y., for construction, and test operation of a Chemical Corps proc facility near Newport, Ind. (Prime contractor, The Li Company).

$13,141,192—**Chrysler Corp.**, Detroit, for repair parts on the missile program.

$8,295,767—**Raytheon Co.**, Waltham, Mass., for ground equi support equipment and engineering services for the missile (four contracts). Contractor has subcontract worl for the following and desires that subcontractors be loca the Northeast area: Drafting services, specifications v technical, manual preparation.

$6,938,450—**Blaw-Knox Company**, Pittsburgh, Pa., for consti of six *Atlas* launching complexes at Forbes AFB, Topeka

$4,800,000—**Western Electric Co.**, N.Y., for research and de ment study for a universal integrated communications (Unicom).

$1,572,334—**Independent Contractors & Engineers**, Dallas, fo struction of launch operations buildings, complexes A, B near Forbes AFB, Topeka, Kan. No subcontracts open.

$1,415,169—**Henry George & Sons**, Spokane, Wash., for operations buildings, site and utilities for SM-64 missile complexes A, B and C, near Fairchild AFB.

$1,000,000—**General Electric Co.**, for outdoor substations and gear for the AF Ballistic Missile Early Warning System near Thule, Greenland (subcontract from Greenland Co tors, Trenton, N.J.).

$430,080—**Ampex Corp.**, Los Angeles, for recorder/reproduce

$385,411—**C. H. Leavell & Co.**, El Paso, Texas, for missile as building at White Sands Missile Range, N.M.

$320,169—**Rheem Manufacturing Co.**, Downey, Calif., for desig development of warheads.

$254,460—**M.B. Electronics, Inc.**, New Haven, Conn., for an grated complex wave vibration testing system.

$219,652—**Western Electric Co., Inc.**, N.Y., for *Nike* spare and components (six contracts).

$170,632—**Consolidated Electrodynamics Corp.**, Pasadena, Cali oscillographs (two contracts).

$167,694—**Douglas Aircraft Co., Inc.**, Santa Monica, Calif., for parts and launching area items (three contracts).

$157,558—**B. B. Saxon**, Fort Walton Beach, Fla., for constr of two Model IV B launcher shelters for G/M launch f at EST site, Santa Rosa Island, Eglin AFB, Fla.

$105,728—**Douglas Aircraft Co., Inc.**, Charlotte, N.C., for spare parts and components (three contracts).

$84,289—**ARF Producers, Inc.**, Raton, N.M., for three miss di indicator ground stations.

$66,854—**Mandrell Industries**, Burbank, Calif., for airborne system.

$61,690—**Cooper Development Corp.**, Monrovia, Calif., for 32 motors, 32 window darts, 62 pyrotechnic fuses.

$50,893—**Dana Corp.**, Toledo, Ohio, for power take-off.

$46,800—**Dynamics Research, Inc.**, Los Angeles, for liquid ni converter.

$43,118—**Anderson-Nichols & Co.**, Boston, for development construction of one data recorder reproducer instrument.

$35,878—**Goodrich-High Voltage Astronautics, Inc.**, Burli Mass., for research on detailed technical scope of first demonstration of thrust.

$35,175—**Union Carbide Corp., National Carbon Co., Div.**, N.Y power pack Y-155 for *M31* rocket.

$25,726—**Beckman & Whitley Inc.**, San Carlos, Calif., fo streak camera with accessories.

Work on

TOTAL SOLUTIONS

to Major Defense Problems

at General Electric's Defense Systems Department

You'll find greater opportunities in Systems Engineering in an organization whose charter has a breadth and scope seldom met in industry:

...to find total solutions to specific large scale defense problems requiring the integration of diverse fields of knowledge and equipments. These problems will be of sufficient magnitude and duration to justify the allocation by General Electric of considerable numbers of highly qualified scientists and engineers to contribute *systems program management* and *systems engineering support*—on programs such as:

ATLAS • DYNA-SOAR • SENTRY

...and other highly classified systems which cannot be listed here.

Immediate Opportunities for:

Systems Program Engineers
Systems Management Engineers
Guidance Equation Engineers
Data Processing Engineers
Electronic Systems Management Engrs.
Operation Analysts
Systems Logistics Engineers
Engineering Psychologists

Forward your confidential resume at an early date. Whereas growth potential here is evident—both for DSD and the engineers who join us—the posirions filled during these early months will carry significant "ground-floor" benefits.

Write fully to Mr. E. A. Smith

Components Reliability: What's Needed?

The velocity of change in the exploding fields of missiles and their related technology is so great that each day's effort brings new concepts, new designs and new developments.

Still there apparently never seems to be a lack of such choice phrases as: "Let's advance the state-of-the-art," or "We have to beat them to . . ." (and you name the astronautical position), etc.

This is all well and good because this nation advances when there's a sense of urgency in the prodding. But it occurs that there's still lethargy in one important area; components reliability.

On page 14 of this issue of M/R, a guest writer makes the point that "too much engineering time and attention has been devoted to perfecting an *assembly* of complicated components, and not enough to perfecting individual parts and—even more important—the basic materials themselves." He says that a by-product of this misplaced emphasis is that much R&D effort is expended not in the laboratory but on the shop or factory floor—*the least efficient and most expensive place for R&D.*

To this we would like to add another tragic fact: Too many thousands of components going into missile systems are *not designed specifically* for the particular missile involved. In far too many instances they're off-the-shelf components usually designed for a variety of applications which too often are either modified or put beyond their performance parameters to fit into a missile system. Missile failures frequently are the costly result.

Let's cite some statistics pertaining to the *Nike-Hercules.* The system consists of approximately 1,500,000 individual parts, ranging in weight from the smallest fraction of an ounce to hundreds of pounds. It contains one quarter of a million feet of wire, two thousand vacuum tubes, and a host of functional components, such as gyroscopes, servomechanisms, and electronic computers. Approximately 80,000 engineering drawings are required to depict the system on paper. The prime contractor utilizes 3300 subcontractors and suppliers scattered across the country. The system alone uses—directly or indirectly—practically every raw material used by American industry, and provides work to some extent for nearly every type of industry in the country.

With so many subcontractors and suppliers it is virtually impossible for the prime, military or major subs, to specify in precise detail the performance parameters for *each* component. What usually happens is that in known critical systems areas, great reliability attention is paid to some components, while other components that might be subjected to the same vibration, shock and g-forces go practically unnoticed. The choice phrase—"random" failure is then offered to the public.

There is the argument that missile systems would be priced out of the pocketbook of the American taxpayer if each component were designed for a *specific* missile application. Components manufacturers themselves are reluctant to fire up assembly lines and produce for a *specific* application. "Why should we," many say, "when we can make one item and sell it to *many* customers?"

But as man prepares for space, government and industry are becoming more cognizant that he is too valuable a commodity to risk on a 98.2% reliability factor. More will be required to satisfy an American public which will become irate and aroused when the first life is lost.

Won't it be a little bit too late then to explain why more emphasis was not placed on this field? This fact should be told now: the reliability standards necessary for man in space will entail far more government action and fund support than has ever been evidenced in the past decade of missile development.

To say that it will be costly is an understatement. But you don't build a high-speed racing car that wins high-performance races by revamping an existing 65 hp engine. In the same way, you don't develop highly reliable spacecraft by using the same parts that are in the home television set.

What do we do about all this? First, it will be up to government to strengthen its present, mostly inadequate reliability requirements to such a par—as the enviable standards being achieved with fuzing and arming. Next, government must furnish the financial incentive for components manufacturers to start designing parts from the ground up. We must insure that components are given the most thorough testing in the laboratory—not in the shop or at a firing range—before they are wedded into the subsystems picture.

Then and only then will we see a *marked* improvement in reliability. Maybe then the scientists can quit sending up missiles with just prayers and hopes. We'll have something we *know* will work. This is as the science of rocketry should be.

NEW PRODUCT BRIEFS

I TUBE. An advanced type of itensifier tube that can "see" ng atom or the faintest star e developed by the Westing- ectric Corp.'s electronic tube r The new tube amplifies the ering at one end to produce an much as 3000 times brighter orescent screen at the opposite st important use of the new expected to be in the nuclear vere it will permit photographic f atomic particle reactions. Two y of Michigan Physicists, Mar- l and Lawrence W. Jones, have used the tube in a luminescent system to produce photographs from the path of a single perticle. Pictures can be taken tube of the minute light scin- that occur when certain ma- re struck by nuclear particles l by "atom smashers." The na- these fleeting scintillations gives formation on the nuclear re- ing observed. In astronomy, the ube cen further intensify the f giant telescopes when viewing et stars, or it could be used in to obtain pictures of far dis- s and galaxies. The tube can y its own output simply by the light output back through with a system of mirrors. Four ubes feeding into each other es would be able to produce of e single photoelectron.

N 225 on Subscriber Service Card.

N:R TUBE. A new high-sensitivity nal counter tube, WL-7243, de- o detect thermal neutrons in range from 8×10^{-3} to 8×10^{5} r/cm²/ second is now available th Westinghouse Electric Corpora- Ctaining an aluminum body, the 24 consists of three individual nal counters; each one inch in et and $10\frac{5}{8}$ inches long and vh BF, enriched to 96 per cent B on-10 isotopy. Operating et ves, the sensitivity of the WL-7243 pximately 13 counts/neutrons/ T pulses arising from incident na photons are sufficiently small based out by suitable discrimina- ir try.

N 226 on Subscriber Service Card.

PULSE GENERATOR. A completely transistorized battery or ac operated pulse generator has been announced by Solidyne. The unit features a design allowing versatile operating characteristics without the penalty of size, weight and heavy power drain usually associated with such units. Compactness and low power drain (less than 2 watts) are accomplished by unique transistorized circuitry. Short-circuit proof 15-volt positive and negative pulse outputs are provided with separately controlled emplitudes. Pulse width can be varied from 0.5 to 100 microseconds with a rise time less than 0.1 microsecond. Repetition rate can be continuously varied between 20 end 5000 pps and provision for en external sync. source is featured. Output pulse delays of up to 100 microseconds and anticipation up to 10 microseconds, relative to sync. output, are also included.

Circle No. 227 on Subscriber Service Card.

MIDGET RELAYS. Kurman Electric Company, a subsidiary of Crescent Petroleum Corp. has introduced the Series 51C Midget Relay; the smallest, lightest plate circuit relay offering self-wiping contacts, dc operation only. Standard adjustment—10 milliwatts. (51CB44D factory adjusted for 5 milliwatt operetion—others can be field adjusted—1 amp contact rating.) Adjustable 2 amp SPDT screw contacts. New rigid front pile-up. Variations—including 5 amp contact, H. S. Military relays coils to 20,000 ohms available. Mounting 2 #6-32 tapped holes on 0.437" centers.

Circle No. 228 on Subscriber Service Card.

OHMMETER. A new technique for accurately measuring low resistances (milliohms) has been devised by Electro Instruments, Inc. Possible applications include measuring the resistance of fuses, conductors and transformer windings. The new instrument will measure resistance to an accuracy or ± 1 milliohm over the full range of 1 milliohm to 9999 milliohms. Sensitivities of 100 microhms are available at slightly reduced accuracy. Scanning and print out modules can be added to form automatic component testing systems.

MISSILE LITERATURE

PRESSURE SWITCHES. Consolidated Controls Corporation, a subsidiary of Consolidated Diesel Electric Corporation, has issued a new condensed catalog covering airborne pressure switches. The catalog lists general-purpose pressure switches, including pneumatic and hydraulic types, high vibration models and differential pressure units. In addition, special application units, such as altitude switches, high-temperature (650-degree Fahrenheit) models and pressure ratio switches, and aircraft gauges are discussed.

Circle No. 200 on Subscriber Service Card.

FERRITE DEVICES. Two new catalog sheets summarizing data on coaxial ferrite isolators and "Tee" ferrite circulators have been made available by Sylvania Electric Products Inc. Sylvania is a wholly-owned subsidiary of General Telephone & Electronics Corporation. Twenty-three types of coaxial ferrite isolators are shown on one of the sheets, covering frequencies from 1 to 11 kilomegacycles. Available units cover an octave of bandwidth over this range. The units offer isolation between 10 and 35 db with 1 db of insertion loss. Any of them can be delivered with up to 80 db isolation, according to Thomas D. Fuller, marketing manager of Sylvania's Special Tube Operations. "Tee" ferrite circulators as small as one-fourth the size of conventional circulators are described on the other sheet. The miniaturization has been achieved in part by designing the units in a shunt T configuration. One of the new units described, the broadband FD-TC501, offers 20 db isolation at 0.3 db insertion loss from 5.925 to 6.425 kilomegacycles.

Circle No. 201 on Subscriber Service Card.

THYRATRON. A new technical bulletin from CBS-Hytron, tells how Thyratron tubes differ from conventional amplifier types. In it, author Bud Tomer explains the mechanism of ionization, describes the "critical characteristic" curve, and discusses the effects of temperature on ionization time and tube life. Installation precautions are also given.

Circle No. 202 on Subscriber Service Card.

GENERAL CATALOG. The Electro Mechanical Instrument Division of Consolidated Electrodynamics Corp. announces the availability of its new General Catalog. The divisions's entire line of dynamic-measuring and recording instruments including oscillographs, data amplifiers and bridge balances; vibration measuring equipment; and power supplies is described. A summary of specifications for CEC standard galvanometers is also included.

Circle No. 203 on Subscriber Service Card.

BROCHURE. A brochure has been released by M. Ten Bosch, Inc. describing three basic Force Balance Pressure Transducers; Static Pressure, Pressure Ratio, and Pressure Difference. Transmission of computed quantities by means of electrical servo loops permits remote indication and tie-in with navigational computers, autopilots and other systems for aircraft and missile control are described.

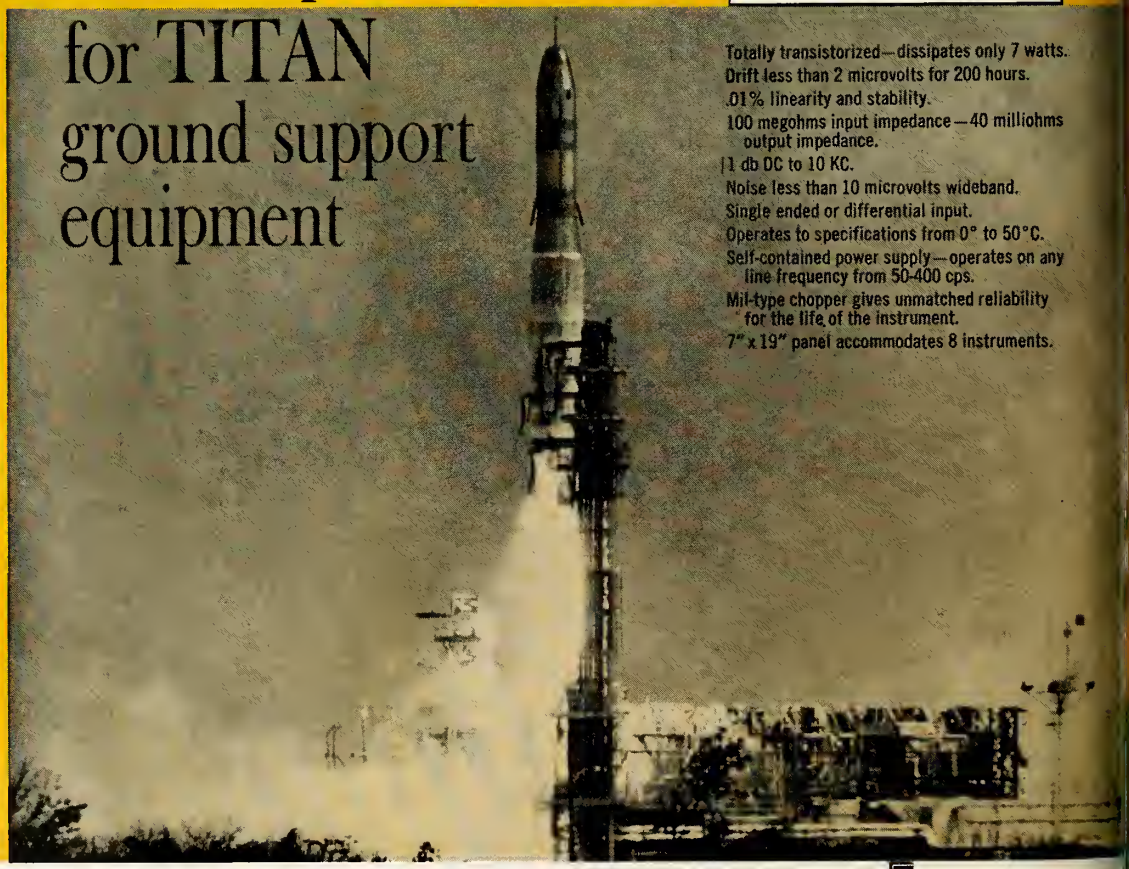
LECTRONIC "MEMORY" SPIN FORGES IDENTICAL PARTS

Dial in" essential engineering data. Hufford Spin Forge forms up to ½ ton of hardest metal ne or a thousand times, without reliance upon human memory or artisanry. Because input is lectronically applied, the effect is "a machine with a memory." Time between tool completion nd delivery of a perfect part is brought to a minimum, because the machine "reports" to ngineering precisely. Given approved data, each new start produces an identical part. Iaterial savings and product uniformity become automatic. Complete automation, never before pplied to machinery of this type, is the important "reason why." For information concern-ng the application of Hufford Spin Forging to your require-ients, write: The Hufford Corporation, 1700 E. Grand Avenue, l Segundo, California...a division of The Siegler Corporation.

HUFFORD

Model A12's pass rugged military environmental tests for altitude, shock, temperature, humidity and electro interference.



Design and construction techniques used in the Model A12 amplifier are fully two years ahead of the field! These advanced techniques enabled the Model A12 to meet stiff environmental qualification tests which resulted in their being selected by Martin engineers for use in the *Titan* ground support equipment.

Use of totally transistorized circuits gives the A12 unmatched reliability and performance, and minimizes heat dissipation problems inherent in vacuum tube instruments. Plug-in etched circuit boards and modular internal construction make servicing and maintenance checks easy—the amplifier can be disassembled and reassembled in less than 10 minutes. *Your E-I representatives can give you complete information.*

Martin picks Electro Instruments D.C. Amplifiers for TITAN ground support equipment

Plug-in attenuators of the A12 provide convenience, flexibility, economy. Special variations, gain settings, etc., can be tailored to your system at no extra cost.

Totally transistorized—dissipates only 7 watts.
Drift less than 2 microvolts for 200 hours.
.01% linearity and stability.
100 megohms input impedance—40 milliohms output impedance.
1 db DC to 10 KC.
Noise less than 10 microvolts wideband.
Single ended or differential input.
Operates to specifications from 0° to 50°C.
Self-contained power supply—operates on any line frequency from 50-400 cps.
Mil-type chopper gives unmatched reliability for the life of the instrument.
7" x 19" panel accommodates 8 instruments.

miniature tape recorder

ACTUAL SIZE

newest new product from Inet!

Testing under severe environments . . . in extremely limited space? Inet's rugged new Miniature Tape Recorder simultaneously records data on 1 to 14 in-line channels, never loses a record because it's built to survive high impacts.

Here are the features to look for: precision in-line recording head; adjustable motor speed and tape tension; molded rubber pressure roller and driver wheels; and precision ball bearings at both ends to support all revolving parts.

Weighs just 24 ounces and operates at tape speeds of from ¼ to 15 inches per second in a temperature range of —50°F. to +200°F. Among its applications: in-flight and static tests; atmospheric, blast, explosion, and wind tunnel studies; and acceleration and actuation tests. *Write today for complete specifications.*

Crosley helps put the "Sunday Punch" in POLARIS

Making sure the Navy's *Polaris* missile detonates at the right time and at the right place is a prime responsibility of Avco's Crosley Division.

A long record of success in the arming and fuzing of many different types of ordnance brought Crosley the Navy Ordnance Laboratory's prime contract for this difficult assignment.

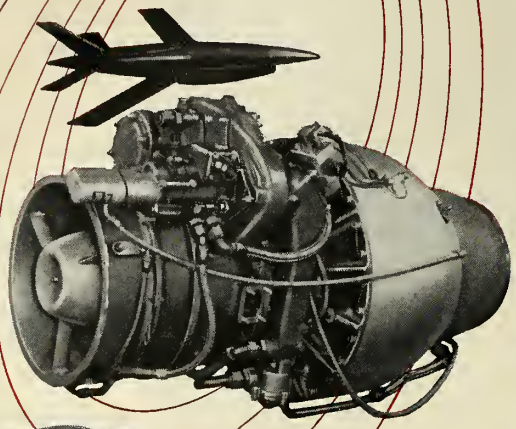
Since first undertaking the task, Crosley has expanded its *Polaris* development work, without once losing step in the demanding *Polaris* timetable.

Arming and fuzing is just one area in which Crosley contributes to the development and performance of missiles. It is the country's leading producer of Command Receivers for missile-range safety applications and for high-performance drones and decoys. It is an important subcontractor to Hughes Aircraft on the *Falcon* missile. Crosley also has contributed to the development of the *Jupiter*, *Sergeant* and *Redstone* missiles.

Crosley's technical competence, dependability, and coordinated project administration are ready to serve the Free World's defense requirements wherever needed most.

For more information, write to: Vice-President, Marketing— Defense Products, Crosley Division, Avco Corporation, 1329 Arlington Street, Cincinnati 25, Ohio.

Avco / Crosley



ENGINEERS!

Creative research and development engineers experienced in electronics, mechanics, weapons systems, and ordnance warheads are urged to investigate the wide range of opportunity at Crosley. Write to: Director, Technical and Scientific Personnel, Dept. M-79E, Avco/Crosley, 1329 Arlington Street, Cincinnati 25, Ohio.

SKY HIGH

integrated hurricane hunting

A sky-high vantage point will be the key to the detection of spawning hurricanes over vast ocean areas such as the Caribbean Sea. Weather satellites equipped with special sensing devices will be able to report cloud patterns and rising columns of warm moist air which indicate the formation of these tropical storms.

Alerted by satellite information, weather reconnaissance aircraft will be dispatched to investigate the hurricane area. These aircraft, with the Bendix AN/AMQ-15 system, will employ high altitude rocketsondes, dropsondes, aircraft sensors, and cloud and storm radars to measure the meteorological and geophysical parameters that make it possible to predict storm intensity and motion.

Measurements of weather phenomena relayed from the AN/AMQ-15 system will be combined with data from land-based weather stations and upper air sites. These data will be integrated and processed by advanced weather computing centers to yield forecasts essential to military operations, commercial aviation and our civilian life.

Advanced weather and geophysical forecasting is the ultimate objective of the AN/AMQ-15 system and related projects being carried out at the Bendix Systems Division. These programs, air defense projects and the EAGLE Air-to-Air Missile program, will provide the integrated systems of tomorrow. Opportunities are available for better engineers and scientists also looking to the future.

A HIGHLIGHT ON CREATIVE SYSTEMS ENGINEERING AT Reeves

PRECISION...ON A SPACE-HIGH PEDESTAL

Reeves has pioneered in the development of extremely high precision two- and three-axis antenna pedestals for fire control, guidance and tracking systems. Reeves-engineered pedestals and related electronic assemblies, including servo systems and computers, are production-ready in types for both land-based and shipboard applications. The pedestals provide continuous rotation in azimuth, with angular travel in the remaining two axes designed to meet particular requirements. Accuracies in the order of 0.1 milliradians can be achieved, with rates of 10 degrees per second, or higher.

REEVES INSTRUMENT CORPORATION

The PLANE

America's newest production bomber, the Convair B58 Hustler. This delta-wing jet employs an area-ruled fuselage for supersonic regime efficiency, and has reportedly been flown in excess of Mach 2 at 50,000 feet. Engines are four J 79's, in pods below the wings.

The PROBLEM

Sealing and cushioning vacuum tubes in cooling air ducts for the B58 Fire Control System, designed and produced by The Emerson Electric Manufacturing Company. Difficulties involved include heat —the sub-miniature tubes operate as high as 350 F— and severe cold when the units are inactive during flight. Protective material must stay resilient despite these extremes.

The PART

SILASTIC
SILICONE RUBBER

Tubes and other electronic equipment in the B 58 are cushioned by molded parts of Silastic®, the Dow Corning silicone rubber. Silastic stays rubbery, has excellent electrical properties.

TYPICAL PROPERTIES OF SILASTIC MOLDED PARTS

Temperature range, °F	—130 to 500
Tensile strength, psi	600 to 1400
Elongation, %	150 to 500
Electric strength, volts/mil	300 to 500

BORESIGHT ACCURACY TO 1/15 MILLIRADIAN? SEE BRUNSWIC

Brunswick-built radomes are setting new highs not only for strength-to-weight ratios, but accuracy as well. The reasons for the accuracy are simple: Brunswick has the test facilities and know-how that are without peer in the industry. Three radome ranges which automatically detect boresight error to an accuracy of 1/12 to 1/15 milliradian are now in full operation at Brunswick.

Soon to be in operation: two 1,000-foot ranges, manually operated, that will assure even more refined accuracy, detecting errors as small as 5 seconds of arc. Also, as an aid to design, quality control and maintenance of electrical tolerances, Brunswick is currently utilizing a one-horn interferometer for accurate IPD measurements and corrections before final range testing.

Behind these extensive test faci ties operates an engineering tea skilled in both detecting and c *recting* boresight error. To lea how this combination of facilit and engineers can give you unique accurate, tough and lightweight domes, write to: Brunswick-Ball Collender Company, Defense Pr ucts Division Sales Manager, 17 Messler St., Muskegon, Michiga

AIR FORCE ROCKET POWER

with pressure vessels by Butterworth in the instrumentation and launching systems

In the launching system for the Air Force's Bomarc, pressure vessels custom-designed and custom-built by Butterworth assure precise volumetric control of liquid nitrogen.

Pressure vessels by Butterworth meet the most rigid requirements for high and low temperature operation. Butterworth experience in the design and building of molds for Naval solid propellants is also available to prime contractors in the missile and rocket field.

Talk to a Butterworth engineer. Or write for "The Butterworth Story", a quick-tour of our complete metalworking facilities.

How far can an engineer go at AC?

Finest "in house" programs anywhere

When you work in AC's instrumentation business, AC offers free comprehensive training programs that will help you graw professianally and enhance your status. Just laok at these opportunities . . .

Program A—far recent graduate engineers—gives you a salid foundation in the theory and application of inertial guidance systems and servamechanisms. You attend classes three haurs per day for four months, all on company time.

Program B—for experienced engineers—consists of upgrading studies in inertial guidance, servamechanisms, environmental problems, engineering math and physics, plus advanced state-af-the-art caurses. Time—during working hours or evenings.

Program C—for all engineering supervisors—involves management training developed by a team af AC executives and University of Chicago industrial relations experts. Sixty ane-half-hour sessions give you a solid grounding in management techniques.

These tharoughly practical courses—taught by university prafessars ar recagnized AC specialists—constitute AC educational "extras." AC offers them in addition ta their educational assistance programs for men who wish ta study far degrees in nearby universities.

You may be eligible for training

If you are a graduate engineer in the electronics, electrical or mechanical fields, ar if yau have an advanced degree in mathematics ar physics, you may be able to participate in these programs while you work on AC's famaus AChiever inertial guidance system or a wide variety af ather electromechanical, aptical and infra-red devices.

Far mare details, just write the Director af Scientific and Prafessianal Employment: Mr. Rabert Allen, Oak Creek Plant, Dept. H, Box 746, Sauth Milwaukee, Wisconsin.

conax®

EXPLOSIVE VALVES

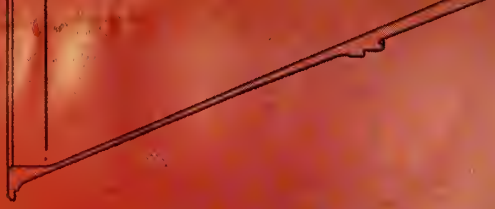
..in mass production for over 5 years!

More than 150 proven explosive valve designs ready for production and 26 models now in mass production provide Conax with the greatest accumulation of experience in this type of hardware.

Aluminum or stainless steel, Conax Explosive Valves operate by firing a small, completely self-contained explosive squib.

Light weight, minimum envelope, "normally closed" Conax Explosive Valves provide dead-tight shut-off before firing and are used for indefinite storage of gases or liquids up to 10,000 psi. Upon firing, flow passage is completely opened in .002 seconds.

"Normally opened" Conax Explosive Valves, when fired, completely stop flow of gases or liquids.



Write for FREE DATA BOOK 5808-XV

Retouched photographs above show a few of the thousands of Conax Explosive Valves that have been made to highest aircraft standards and put into operation on missiles.

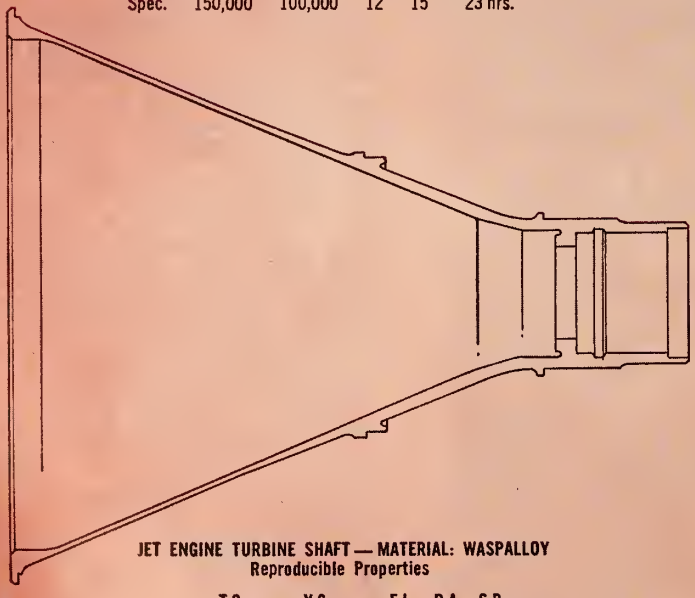
A NEW HIGH

IN METALLURGICAL PROPERTIES FROM EXOTIC METALS

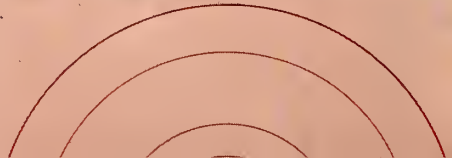


JET ENGINE TURBINE DISC — MATERIAL: INCO 901

	T.S.	Y.S. .2%	E.L.	R.A.	S.R. 1200° F. 80,000 lb./sq. in.
	175,000	128,000	20	23	225 hrs.
Spec.	150,000	100,000	12	15	23 hrs.

Jet engine components made from Cameron forgings have hit a new high in forming and in metallurgical refinements, developing not only room temperature properties 20% over specifications but, more importantly, producing these same over-specification values at elevated temperatures.

With our special forging techniques, one heat and one push produce uniform properties from surface to center, and from hub end to flange end. Even in high density alloys, interesting economy is effected. Favorable billet to finished forging weight ratio means less of the expensive material is used in each operation. Because of improved grain structure and close controls throughout the entire process, machining qualities are excellent.



JET ENGINE TURBINE SHAFT — MATERIAL: WASPALLOY
Reproducible Properties

	T.S.	Y.S. .02%	E.L.	R.A.	S.R. 1350° F. 70,000 lb./sq. in.
	196,200	131,700	23	32	71 hrs.
Spec.	160,000	90,000	15	18	23 hrs.

All this, of course, gives our customers a better component functionally and economically. Check the accompanying comparison of the specification values and obtained values on the two jet turbine rotating components shown—let us show you what we can do with your problem forgings—just CALL, WRITE, or COME BY

PRODUCT SUPPORT ENGINEERS

Urgency–Speed–Reliability. These words describe Convair-Astronautics' top-priority program of activating Atlas ICBM bases throughout the United States. Included in this immense task is the job of training Air Force personnel, developing and producing hundreds of technical manuals and providing technical assistance to the Air Force. The Product Support department at Astronautics is responsible for this assignment and to fulfill it must double in size within the next two years. Engineers qualified to participate in this long-range program will find excellent growth opportunities in the following areas:

CUSTOMER TRAINING – Service Training Instructors—Engineers with degrees in ME, AE or EE, or equivalent hardware experience are needed to prepare and conduct continuing 4-6 month courses to Air Force personnel on the Atlas ICBM. This training will include classroom theory and hardware manipulative skills to a high level of proficiency.

Service Training Planners – Men with 2-5 years experience in the planning of industrial and/or armed services training programs are needed for the planning, preparation, editing and publishing of training material for the Air Force. This assignment will also include training standards, syllabuses, lesson plans and training projects.

TRAINER DESIGN – Trainer design engineers (electronic and mechanical) with degrees in ME, AE or EE are needed to design simulators to be used in the training of Air Force personnel on the Atlas weapon system.

FIELD SERVICE – Engineers, preferably with degrees in ME, AE or EE, and field or in-plant hardware experience are needed to act as technical representatives to the Air Force on the Atlas ICBM. Most assignments will be at Vandenberg AFB, Santa Maria, Calif. There will be other assignments as additional Atlas bases become operational. A limited number of San Diego openings also exist in the areas of Field Service Support. A field service bonus of $210.00 per month is authorized for field assignments in excess of six months. Per diem paid for assignments under six months.

TECHNICAL WRITING – Engineering degree preferred, plus 1-3 years of technical writing experience. Assignments include the writing of engineering reports, maintenance manuals and operation manuals.

Our engineering representatives will be conducting

INTERVIEWS

Qualified Product Support Engineers are urged to send a detailed resume at once so advance arrangements can be made for a confidential interview. Write to Mr. T. W. Wills, Engineering Personnel Administrator, Department 130-90.

CONVAIR/ASTRONAUTICS

CONVAIR DIVISION OF

GENERAL DYNAMICS

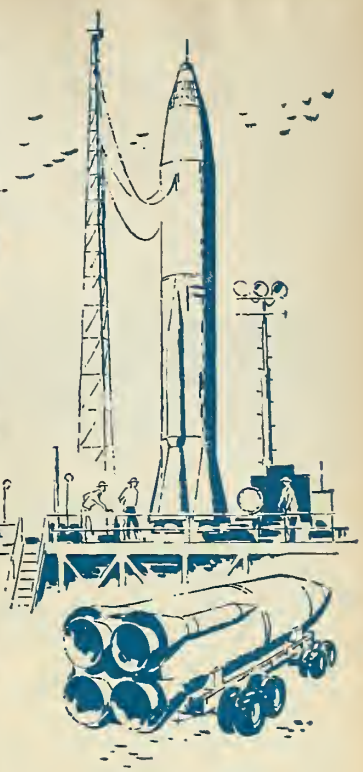
5519 KEARNY VILLA ROAD, SAN DIEGO, CALIFORNIA

STRAIGHT TALK TO ENGINEERS

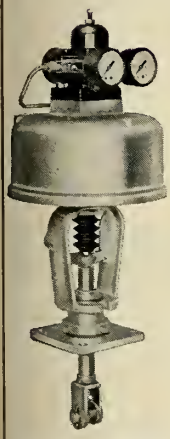
from Donald W. Douglas, Jr.

President, Douglas Aircraft Company

I've been asked whether non-aeronautical engineers have good prospects for advancement in the aviation industry.



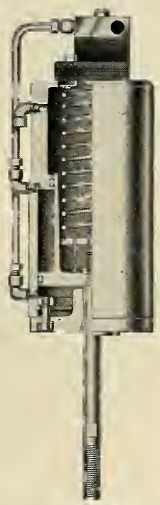
The answer is *yes, definitely!* At Douglas many of our top supervisory people have moved up from other engineering specialties. The complexity of modern aircraft and missiles requires the greatest variety of engineering skills known to industry.



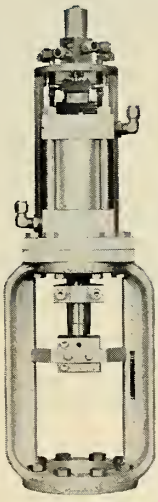
For example, we now have pressing needs for mechanical, structural, electrical and electronics engineers in addition to aerodynamicists, physicists and mathematicians. Whatever your background in the engineering profession may be, there are prime opportunities in the stimulating aircraft and missiles field.

Please write to Mr. C. C. LaVene
Douglas Aircraft Company, Box 620-R
Santa Monica, California

Annin OFFERS YOU MORE IN ACTUATORS

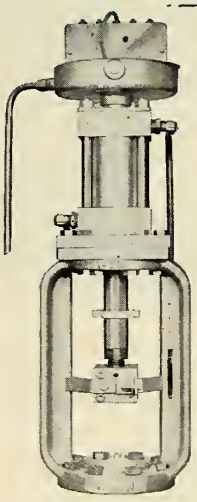


Your choice OF ADVANCED DESIGNS WITH MORE PRECISE POSITIONING AND DYNAMIC RESPONSE CHARACTERISTICS



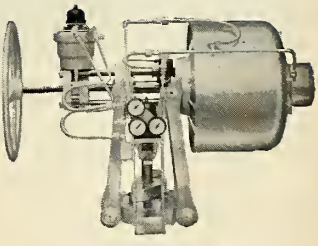
1542 & 1544 SERIES DOMOTOR POWERED ACTUATORS

Two types, "Direct Thrust" (illustrated) or "Lever" units are available for any application requiring accurate positioning in response to a pneumatic signal, such as butterfly valves, dampers, turbines and engine governors. Guaranteed positioning accuracy of better than 0.001" per inch of stroke over the complete range of piston travel is combined with a smooth operating action that provides an accurate, stable output force.



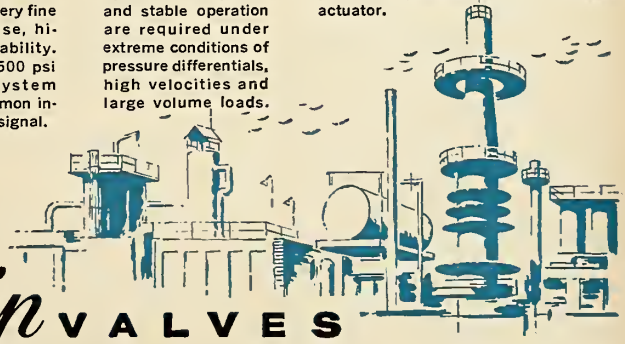
600 SERIES STROKE POSITIONING ACTUATORS

Offered primarily for the control of variable speed drives, rheostats, pumps and cams, as well as control valves, with strokes up to 6 inches and forces up to 2510 pounds of thrust. Compact and rugged, for easy mounting on existing equipment. May be operated from a standard 3-15 psi instrument signal, with a positional accuracy within 0.001" per inch of stroke.



10,000 SERIES PNEUMATIC-HYDRAULIC ACTUATORS

For valves requiring strokes to 6 inches and thrusts to 100,000 lbs. Furnished on body assemblies where process conditions require very fine valve response, hi-speed and stability. Operate on 1500 psi oil supply system from any common instrument air signal.



20,000 SERIES ELECTRO-HYDRAULIC ACTUATORS

Provide a means of converting an electrical signal to a powerful hydraulic positioning force, where high speed of response and stable operation are required under extreme conditions of pressure differentials, high velocities and large volume loads.

TOGGLE ACTUATORS

For process requirements where the unbalanced forces are extremely high, or where large through-puts are required. Three types are offered: pneumatic positioning, pneumatic on-off, and manual control, all embodying the toggle actuator; or a manual control arrangement can be combined with the pneumatic positioning or on-off toggle actuator.

COUNT DOWN

for the conquest of space

"MISSION ACCOMPLISHED: DEPARTING LUNA 2205 ZEBRA"

This message, flashed across a quarter-million miles to Washington, D.C., will be awaited anxiously by millions.

But even then our first expedition to the moon will still face its most crucial test—the journey home to earth.

The success of that trip will depend in large part on rocket propellants—fuels and oxidizers that will have been stored for days in the tanks of the expeditionary vehicle and yet will respond instantly when needed.

Storable liquid propellants is one of the fields in which Rocketdyne has anticipated the future. For more than ten years, its propellant chemists have been studying, engineering, and testing combinations of storable fuels and oxidizers for greater storability and higher energy.

Storability PLUS high energy

Rocketdyne has tested these combinations in all production and experimental engines. The results prove that today's storable fuels and oxidizers have these important capabilities:

(1) High performance, even after months or years of storage; (2) Stability over a wide temperature range, permitting storage in missile tanks without rigid environmental controls; (3) Dependable performance, predictable even at extremes of heat and cold; (4) Instant readiness for firing at any time during the storage period; (5) Energy yields equal to or higher than those of conventional propellant combinations.

Second-generation missiles

The tests also prove that engines developed for conventional propellants can be converted to storable combinations rapidly and inexpensively—a significant consideration in the development of second and third generation strategic, tactical, and air defense missiles.

Significant, too, is the *potential* performance of storable combinations. Research points to energy yields as high as 400 seconds of altitude specific impulse—performance 20 percent higher than that of today's combinations. These high-energy yields will offer new capabilities and greater flexibility for America's scientific and military programs.

Stepping stones to Space

Rocketdyne has designed and built much of today's operating hardware in the high-thrust rocket field. Engines by Rocketdyne power most of the military and scientific projects sponsored by Air Force, Army, and NASA. This experience now becomes the point-of-departure for tomorrow's journeys into the unknown.

POWER FOR AMERICA'S MISSILES

Thrust chamber production line for Thor and Jupiter at Rocketdyne's Neosho, Mo., facility moves smoothly.

FIRST WITH POWER FOR OUTER SPACE

ROCKETDYNE

A DIVISION OF NORTH AMERICAN AVIATION, INC.

Washington Countdown

IN THE PENTAGON

Which military service will run . . .

the new satellite detection fence is up for decision at the Pentagon's top levels. The command could encompass all U.S. military tracking facilities around the world. All three services want the job.

• • •

Recent Soviet 'Zooniks' . . .

may have soared some 1000 miles into space before returning to earth. The Russians aren't saying, but this is the educated guess of a number of U.S. experts. The flights obviously are aimed at collecting data on survival in space.

• • •

Pentagon sources complain . . .

that the GAO—Congress' fiscal watchdog—is stepping out of bounds in checking up on military expenditures. They say GAO is not only checking up on fiscal matters but also making judgments on the reliability of weapons.

• • •

No extensive delays . . .

in the *Discoverer* satellite schedule are now expected to result from recent failures. ARPA and the Air Force had planned to launch *Discoverer V* about the end of July. The shot is expected to be a full equipment checkout. No wildlife.

• • •

Behind the scenes an AF fight . . .

is shaping up over handling of weapon systems development. The trend appears to be moving toward greater centralization. A top-level AF committee is studying the question.

ON CAPITOL HILL

The House-cut NASA budget . . .

probably will stay cut—at least in part. But NASA appears to have little to worry about. Whatever dollars are lost in the first round are fairly certain to be regained by slipping them into a FY '60 supplemental appropriations bill later on.

The Hébert Subcommittee investigation . . .

into hiring of ex-military officers by defense contractors is scheduled to get down to specifics in its new round of hearings. Among other things, the subcommittee wants definitions of such activities as "selling," "promoting," and "negotiating."

At NASA

Would an astronaut die . . .

if the **Convair** *Atlas* designed to boost him into space exploded on the launching pad and the *Mercury* escape system failed to blast him free? NASA experts say no. The heat-resistant escape capsule would save him anyway.

• • •

But, incidentally, the strain . . .

of the ride to safety in an escape capsule is nothing to look forward to. If the *Mercury* capsule is blasted free from ground level, the astronaut will have to sustain as much as 20 g's for about one second.

• • •

Testing of Big Joe . . .

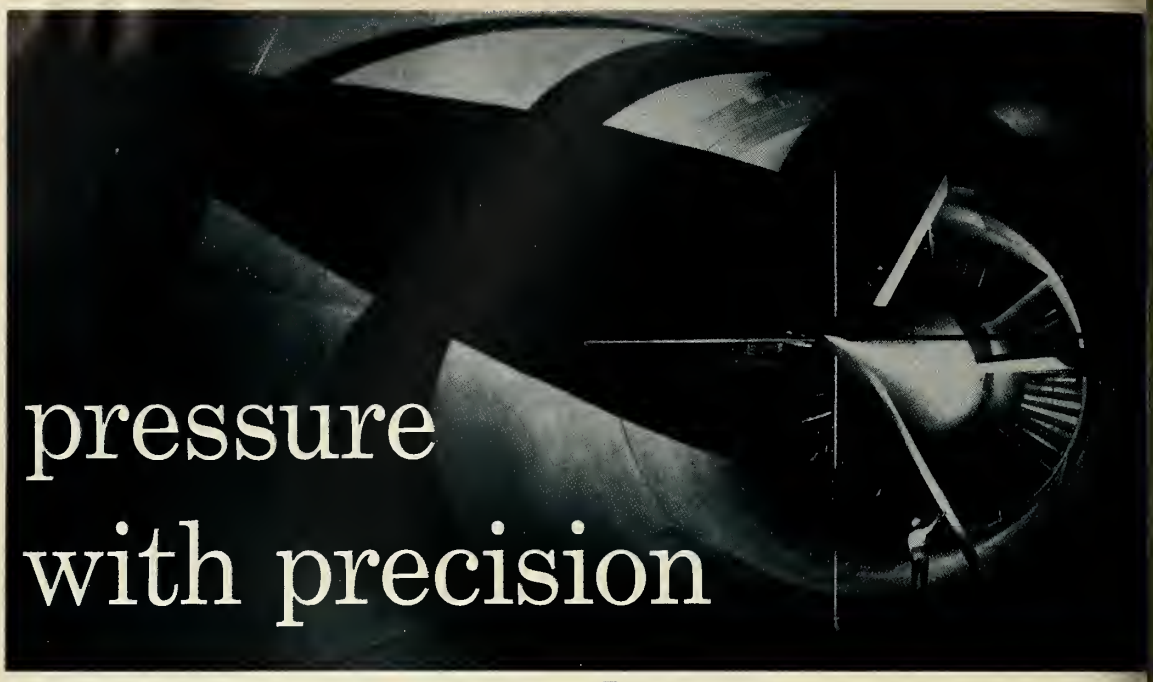
the boiler plated capsule mounted on top of an *Atlas*, will begin in late summer. The shots, which will test the capsule's heat shield on re-entry, have been delayed because of the recent defects discovered in the *Atlas* vehicle.

• • •

Chrysler's *Jupiter* may be put back . . .

in the *Mercury* program for budgetary reasons. NASA would like to use *Atlases* for the early *Mercury* tests. But cheaper *Jupiters* may have to be used because of congressional cuts in NASA's budget.

AROUND TOWN



Some of the reports . . .

that are being passed as the "latest" in the nation's capital:

. . . The French will explode their first A-bomb in a matter of months and begin developing nuclear warheads for missiles.

. . . Officials are worrying about a new Red power play in troubled Latin America's Possible Soviet goal: missile bases at America's back door.

. . . Top civilian scientists fear they see a trend back toward starving civilian federal research programs in favor of military research.

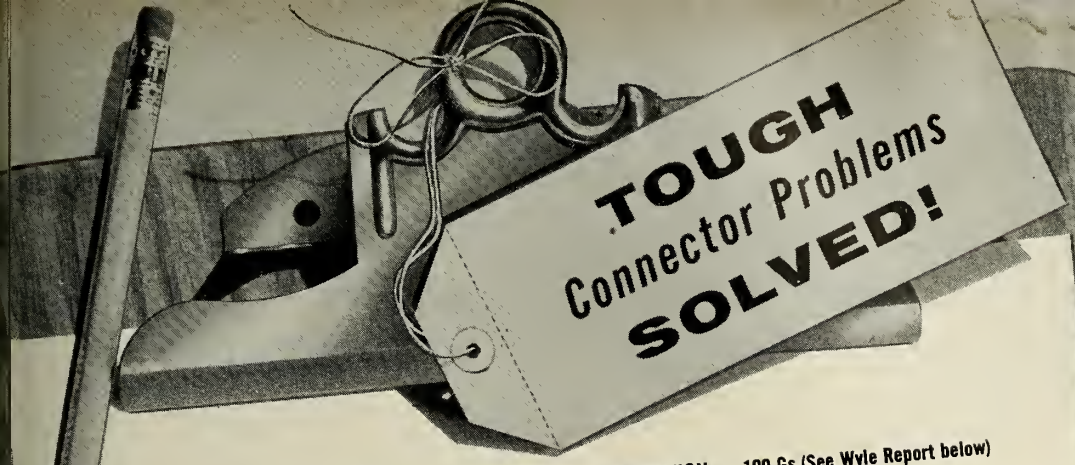
pressure with precision

When critical pressures must be delivered or measured, Consolidated Systems are on the job, surpassing design specifications. Digital pressure measurement for windtunnels, automatic calibration of pressure transducers, missile propellant systems checkout with accuracies of one part in 2,000... these are being accomplished day-in and day-out, with precise pressures delivered at the turn of a dial. This type of performance is available for your application. Write for the complete story in Bulletin 3018-X5.

Consolidated Systems CEC

CONSOLIDATED ELECTRODYNAMICS *300 N. Sierra Madre Villa, Pasadena, Calif.*

FOR EMPLOYMENT OPPORTUNITIES WITH THIS PROGRESSIVE COMPANY, WRITE DIRECTOR OF PERSONNEL



Pressure transducer calibration system controls and measures pressures from 25 pickups in ranges from 1.5 to 500 psi. Linearity, hysteresis, zero, and sensitivity characteristics are determined at a specified temperature in 2½ minutes.

Propellant Utilization System Exerciser checks missile system performance by generating precise pressures for fuel and oxidizer channels at preselected points. Twenty-one similar systems are now in use at missile test sites.

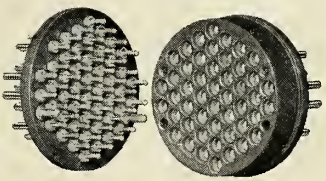
*Under development



Many tough electrical connector problems have been submitted to Cole Electric Co. in recent months. Because of the ability of revolutionary new Cole self-aligning ball-and-socket connector pins to operate under extreme conditions, all of these problems have been or are being solved. Special Cole Connectors with up to 1000 contacts have been developed to meet difficult environmental and operational requirements for aircraft, missiles, ground support, computers, nuclear, electronic and electrical equipment.

Whatever your connector problem might be, a special Cole Self-Aligning Connector may provide the practical solution. Virtually any size or configuration with any number of contacts can be made. Four pin capacities: 15, 30, 75 and 300 amp. Highly specialized fittings in stainless, phenolics, fiber glass, nylon, ceramic or other materials.

Our complete research and development facilities are at your disposal. Write or phone today.

Cole ELECTRIC CO.

8439 Steller Dr., Culver City, Calif. • UP 0-4701

Tested to 100 Gs

In recent tests conducted by Wyle Laboratories of El Segundo, Calif., Model B-3106 Cole Connectors were subjected to vibration scan from 5 to 2000 cps. Each connector contained 15 contacts, wired in series. At vibrations up to 100 Gs amplitude there was no evidence of contact opening. Noise levels were exceedingly low. Full test report available on request.

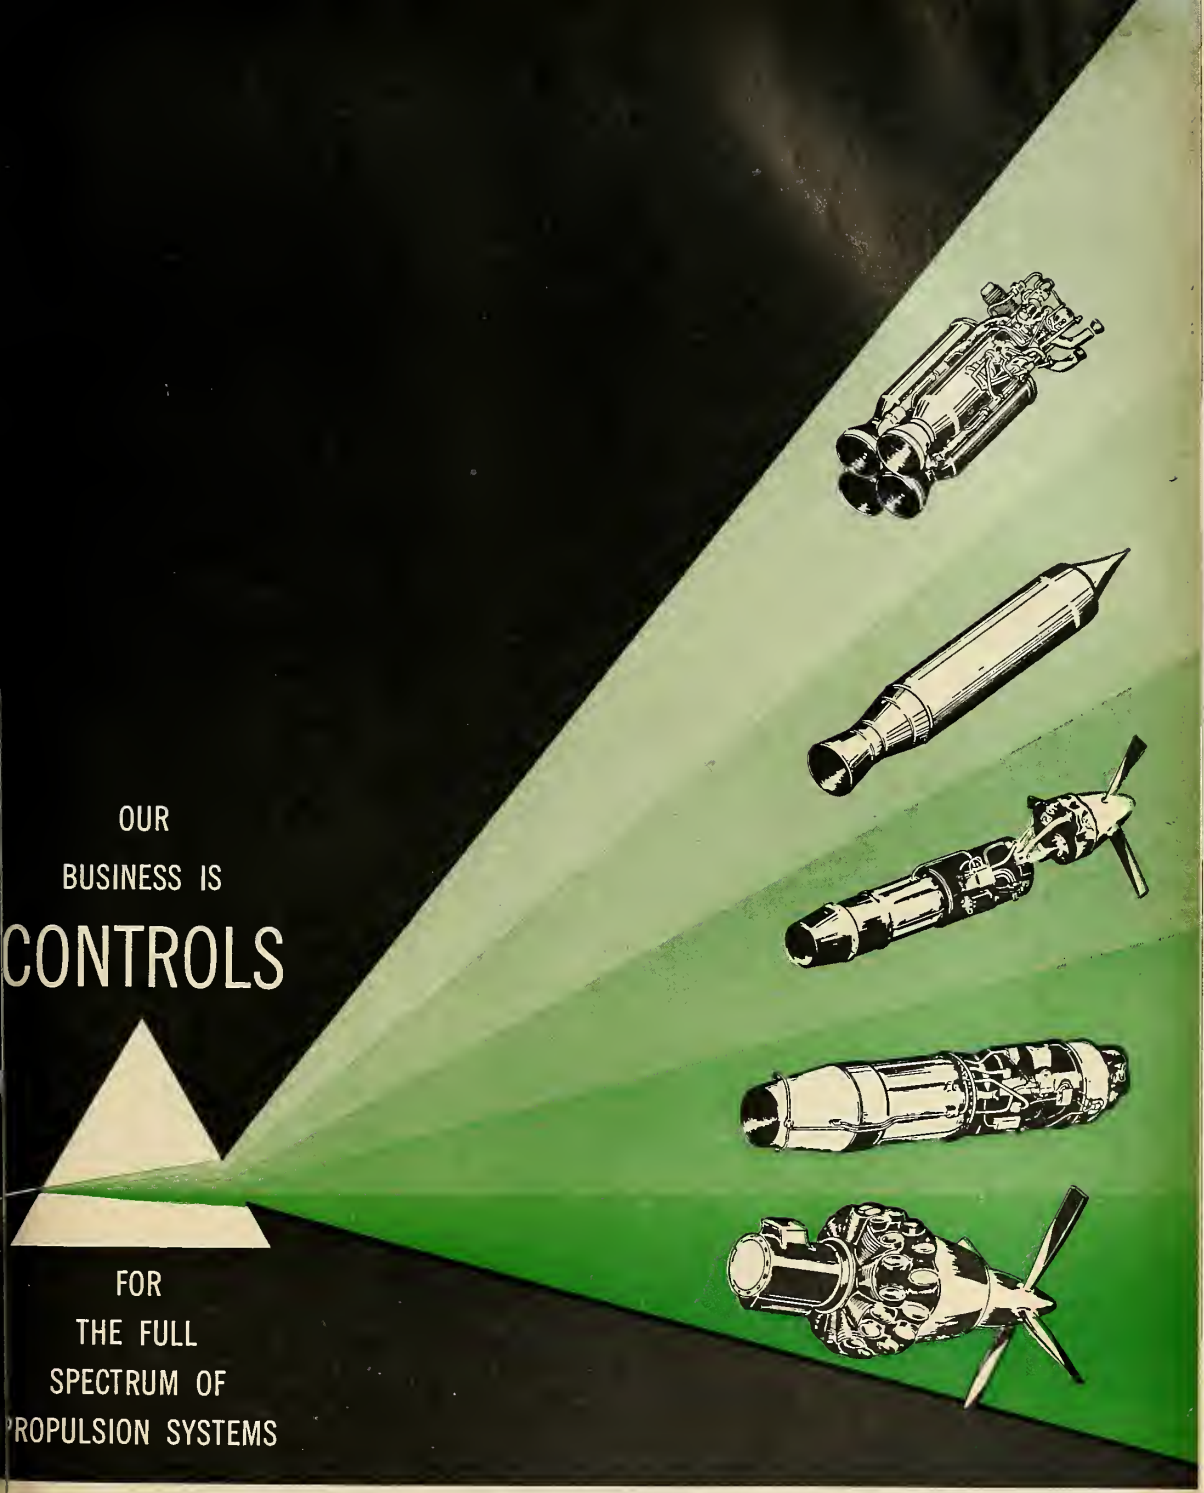
Ability of energy to do work?

A mathematical convenience?

Gibbs' Free Energy?

What does it mean in isothermal electrochemistry?

The concept of energy availability in all its ramifications is becoming ever more important to Allison's energy conversion mission.



Current projects involving this concept include electrochemical conversion systems (for satellites, space systems, and perhaps even your future automobile), heat regenerator systems and photolysis regenerators.

In our inquiries we rely not only on our own resources but also on the talents of General Motors Corporation, its Divisions, and other organizations and individuals. By applying this systems engineering concept to new research projects we increase the effectiveness with which we accomplish our mission—exploring the needs of advanced propulsion and weapons systems.

Energy conversion is our business

For Control of Accidentally Ignited Missiles ... Fire Detector-Water Injection Nozzle

Missiles are among the most destructive weapons in our fast-growing arsenal. Their storage, particularly aboard naval craft, creates critical problems. So Grinnell and the Navy collaborated on the development of this Fire Detector - Water Injection Nozzle. This device is actuated by shock waves should fire start in a missile booster. Then, almost instantaneously, the nozzle delivers a stream of water to control or extinguish the burning.

The same experience in solving tough fire problems is available to you. Let Grinnell be responsible for the fire protection on your next installation—whether it requires standard equipment, or special development work. Remember, Grinnell's specialty is fire protection . . . with a background of successful research, engineering, manufacturing and installation for 89 years. Grinnell Company, Providence 1, Rhode Island.

GRINNELL

Research, Engineering, Manufacturing and Installation of Fire Protection Systems since 1870

When man first steps into the vehicle that will carry him into outer space, it will be with complete confidence.

He knows that he can rely on the extensive testing and preparations that have gone before. Flexonics has played a vital part in these preparations—engineering, designing, and manufacturing metal and synthetic components and systems for hydraulic, pneumatic, liquid oxygen, and fuel applications on America's best-proved missiles and aircraft.

You can draw on this unequalled experience, too, by contacting your Flexonics sales engineer.

Industry Countdown

STRUCTURES

Satellite rendezvous . . .

system is being researched by **Norair Division** of **Northrop Corp.** Concept is to permit maneuverable manned satellite to couple in space with life support satellite in permanent orbit. Hook-on would be effected through target satellite controlled approach (TSCA)—space version of aircraft ground controlled approach, or through maneuverable satellite landing system. MSLS would utilize search-and-track radar beacon aboard target satellite with pilot performing terminal phase guidance and coupling through visual observation.

• • •

'Super' *Hawk* . . .

is under research and development by the Army. On the operational **Raytheon**-built *Hawk* low-flying anti-aircraft missile, the Army is planning to spend an additional $127 million in FY 1960. Plans call for 15 *Hawk* battalions—13 operational in mid-1961.

• • •

Reports are current in France . . .

that De Gaulle hopes to get help from **Boeing** in producing a solid-fuel IRBM of his own. Advisors have told him that the cost, plus production of an atomic warhead would be a prohibitive 18 billion francs (about $3½ billion) or more. The French almost-ready atomic bomb is presently uncomfortably large for an aircraft, let alone a missile warhead.

• • •

Government recognition . . .

of the missile industry won't be possible for at least two years. It takes that long to make the change in the Standard Industrial Classification of the Census Bureau. Argument is under way now whether missiles should be classed as ammo/ordnance, lumped together with aircraft or treated separately in the 1958 census of manufacturers listing dollar value of contracts. This will be published in 1960.

• • •

Total of $384 million . . .

so far has been awarded **The Martin Co. Denver Division** for design, fabrication and test of *Titan* ICBM. Recently, ARPA chose modified first stage of *Titan* as second stage of 200-foot, 1.3 million pound thrust *Saturn* space vehicle.

• • •

Timetable for missile cruiser . . .

Long Beach to be ready for action is early 1961. The *Talos*- and advanced *Terrier*-carrying nuclear-powered warship was launched at the **Bethlehem Steel Co.** shipyard in Quincy, Mass., on July 14. Outfitting will take until late next year.

PROPULSION

Dynasoar propulsion . . .

systems proposals are being reviewed by Source Selection Board composed of AMC, ARDC and SAC officials. **Boeing** concept would use *Atlas* or *Titan* to blast off the boost-glide space vehicle, while **Martin-Bell** proposes using *Titan* only.

• • •

Saturn at lift-off . . .

will weigh about 580 tons—500 of it fuel. Booster for the 1.3 million pound thrust vehicle is cluster of eight H-1 **Rocketdyne** engines.

• • •

In pop-up tests . . .

of full-scale mockup *Polaris* at San Clemente Island, Calif., **Lockheed** is using 186-foot barge-mounted crane to catch the instrumented missile in the air. Operation is called "fish-hook."

ELECTRONICS

Western Electric has won . . .

the $25 million-plus NASA contract to construct the Project *Mercury* world-wide tracking range. On the **Western Electric** team are **Bell Telephone Laboratories, International Business Machines, Bendix Aviation Corp.** and **Burns and Roe, Inc.** Formal contract negotiations will begin this week.

• • •

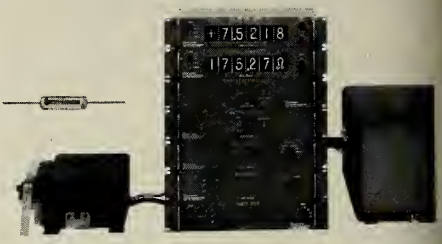
Improved Azusa Mark II . . .

tracking system is being readied by **Convair Astronautics** for installation soon at Cape Canaveral under $1.7 million contract. Azusa circuits presently are aboard *Thor, Jupiter, Polaris, Atlas* and *Titan*. Mark II, which employs continuous microwave signal showing velocity and position, will be installed in second generation missiles and space vehicles.

ASTROPHYSICS

The Czechs are setting up . . .

an astronautics commission in the country's Academy of Sciences. But reports from the Iron Curtain country say the commission will not participate in any satellite or rocket launchings. Activity will be confined to optical, photographic and radio observation of cosmic activity.



• • •

"Moon garden" of snap beans . . .

carrots and turnips is being grown in pressurized vessels by **Republic Aviation** researchers. Project is aimed at determining the feasibility of growing crops to support a lunar base. Results so far indicate that little germination results in seeds planted in simulated altitude of 46,000 feet.

Low cost, versatile DIGITAL SYSTEMS

for automatic testing of transistors resistors diodes and capacitors

Small E-I automatic digital systems provide many advantages. First, they cost less. This is primarily the result of large-quantity manufacture of modules which make up the E-I system. Cost is almost a linear function of performance capabilities desired in the system.

Second, they are exceptionally versatile. The E-I system can be expanded simply by adding appropriate modules. Typical systems presently in use measure resistance, capacitance, DC and AC voltages, DC/DC ratios, AC/DC ratios, AC/AC ratios and combinations of these. Measurements to four or five digits can be visually displayed and printed out at rates up to five readings per second. Operation can be semi- or totally automatic with go/no go comparison of values and programmed readout at periodic intervals. Scanners can be provided for scanning thousands of single and multi-wire input channels. In brief, the E-I system has an extensive scope of operating capability.

Third, E-I systems provide unmatched reliability. Where practicable, circuits are totally transistorized. The use of etched, plug-in circuit boards, and modular internal construction make maintenance checks and in-plant repairs easy.

Typical E-I system for evaluating components—includes 100 channel input signal scanner. Can digitize DC voltage, resistance, AC voltage and DC/DC voltage ratio analogs. Digital equivalents are recorded on strip printer for "quick look" data and on punch paper tape for additional data reduction by digital computer.

Lower cost, maximum versatility and greater reliability—if you want these advantages in your component test system, contact your nearest E-I representative. He can give you complete information or answer any specific questions you may have.

RODUCER OF THE GREATEST NUMBER OF HIGH PERFORMANCE* MISSILE MOTOR CASES IN AMERICA

PMR Outlines Plans To Spend $30 Million

by Robert Mount
Special M/R Correspondent

OXNARD, CALIF.—Pacific Missile Range development of downrange and coastal facilities moves into high gear this fiscal year with $30 million in expenditures authorized.

Island facilities at Eniwetok, Wake, Kaneohe Bay, Midway and Kwajalein are under way, and some modification of the tracking station at Ka Lae, South Point, Hawaii, may also be in the cards.

In addition, PMR will develop new instrumentation facilities at Point Montara, near San Francisco; Granite Canyon, on the Monterey Peninsula; Piedras Blancas, west of Paso Robles; Point Pillar, south of Point Montara; and at Laguna Peak, next to Pacific Missile Range Headquarters, Point Mugu.

Expenditures at PMR headquarters itself this year will total about $18 million, with nearly $10 million more earmarked for Point Arguello development. Launching pads for the Air Force project, WS-117L (Project *Sentry*) are under construction at a contract cost of over $5 million at Point Arguello. *Sentry* is the advanced reconnaissance satellite, still listed in Air Force releases under that name. It will utilize **Convair's** *Atlas* for a booster and a **Lockheed**-developed satellite stage.

• **For the islands**—Island development planned this year includes:

• Eniwetok—Communications data link with Wake Island, to handle missile impaction location data, $317,000. SOFAR MILS (Sound Frequency and Ranging/Missile Impact Location System) installation, $435,000. Sounding rocket facility to obtain high-altitude meteorology data, $22,000. Such data are essential for operations involving nose cone re-entry and missile impact data collection.

• Wake Island—Expansion of Federal Aviation Agency transmitter building, $93,000, needed because ICBM target area is near Wake Island and impact data must be transmitted. Wake is one of several PMR stations in what eventually will become Naval Missile Facility Western Pacific. Another $190,000 will be spent here for civilian bachelor quarters this year.

• Midway—SOFAR MILS installation, $435,000.

• Kaneohe Bay—SOFAR MILS installation, $486,000. PMR Hawaiian Islands communications center located at this Marine Corps Air Station will cost another $123,000.

• Ka Lee, South Point, Hawaii—Although no money is explicitly earmarked for this site, recently acquired from the Air Force in a transfer, it has been reported that this deep space tracking station may be modified to increase its ICBM tracking capabilities.

• **On the coast**—Instrumentation along the West Coast budgeted for this year includes:

Instrumentation stations with portable communications and tracking equipment at Point Montara, Granite Canyon and Piedras Blancas, to cost a total of $423,000.

At Point Pillar, the Navy will construct permanent instrumentation facilities costing $545,000, and $63,000 more in photographic and calibration instrumentation for air-to-air and air-to-surface missiles.

A new remote monitoring building atop Laguna Peak, near PMR headquarters at Point Mugu, will extend monitoring coverage to the Los Angeles Basin, presumably to refine current capabilities for frequency screening and interference control.

At Point Mugu, the following major construction is planned:

Roads, $3 million; missile project building, $2.9 million; armament test project building, $2.4 million, which may herald transfer of some armament system studies from Patuxent River, Md., to Mugu; PMR headquarters building, $1.8 million, to house about 600 administrative and operations personnel by 1961; parking facilities and flight aprons, $1.1 million; instrumentation facilities $750,000; frequency control facilities $580,000.

At Point Arguello, planned inter-service and inter-agency launch site for PMR, the following are approved:

Roads and facilities, $5 million; security facilities, $955,000; central launch control building and missile assembly building, each costing $873,000; multipurpose Marine detachment quarters $410,000; range users' engineering building, $400,000; second unit of radio receiver station, $238,000; operational computer center, $233,000; ordnance assembly building, $200,000; public works shop, $150,000; launch site support, $65,000.

Beryllium Heat Sink Is Forged for *Mercury*

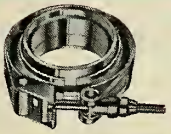
CLEVELAND—An 80-inch saucer-shaped beryllium disc has been forged for heat-sink service in the Project *Mercury* space capsule.

A 50,000-ton press at the **Alcoa** plant here squeezed a steel-jacketed beryllium billet into the shape desired at a temperature of 2000° F. **Brush Beryllium Co.** hot-pressed the 62-inch billet by a patented process involving simultaneous application of vacuum, heat and pressure.

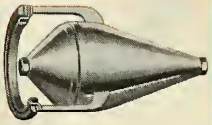
After preliminary machining by Brush, Alcoa heated the billet in a special furnace. Then a huge manipulator placed it on a pre-heated die and pressed it to 3 inches thick. The forged part goes back to Brush for precision finish machining, after which Alcoa will perform ultrasonic inspection.

The shield will form part of the outside covering of the capsule, for which **McDonnell Aircraft Corp.** is prime contractor. The shield will be the leading face of the chamber on the return to earth. The piece is one of a series of beryllium forgings Brush and Alcoa will produce for *Mercury*. Beryllium was chosen because it is only a fifth the weight of steel and is an excellent heat absorber.

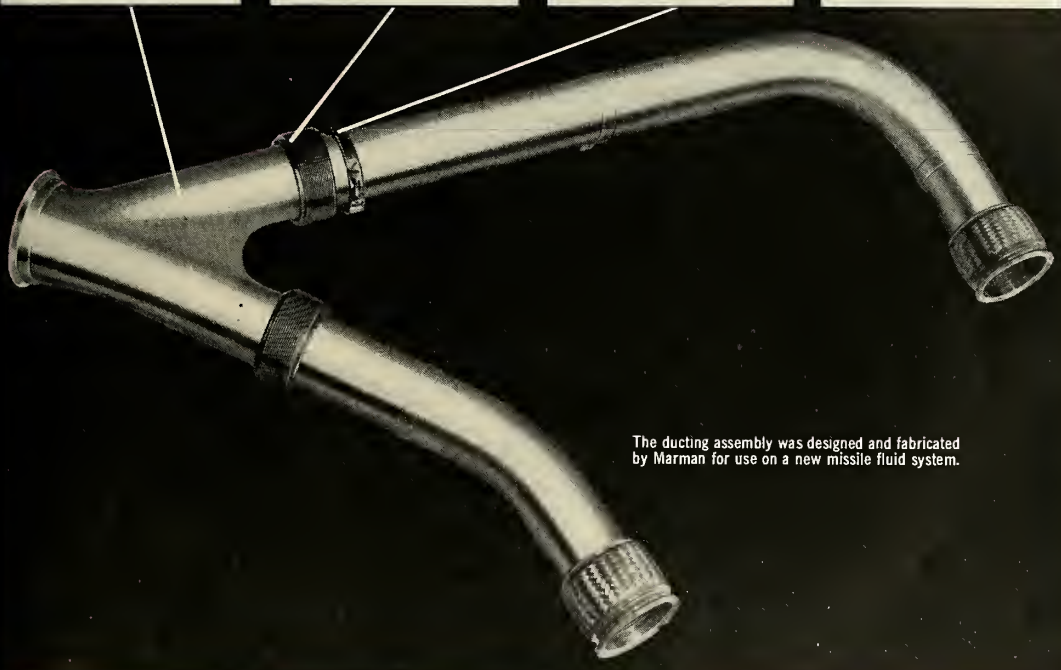
Only MARMAN makes all four!



DUCTING...BELLOWS...JOINTS...VALVES



Stainless steel and aluminum ducting in any configuration.



Straight, link and gimbal type bellows assemblies.

High performance tube joints for all pressures and temperatures.

In-line check valves to meet bleed air requirements.

The ducting assembly was designed and fabricated by Marman for use on a new missile fluid system.

NOW YOU GET COORDINATED ENGINEERING AND MANUFACTURING FROM ONE SOURCE

Let Marman simplify your problems of designing and procuring duct assemblies for missile fluid systems. Marman provides highly competent, start-to-finish engineering assistance. And, only Marman manufactures the full range of components required to produce complete duct assemblies for low, medium and high performance systems.

Marman's wide experience and extensive facilities assure expert fabrication of ducting, bellows, joints and valves into precision assemblies. Engineering and manufacturing facilities are coordinated to meet your lead time requirements. To get full information, return the coupon below.

Global telephone calls via satellites brought nearer by a new ITT electron tube

From the nation-wide resources of ITT Laboratories has come the ultimate development in a unique electronic amplifying device called the *traveling wave tube.*

A four-foot version pioneered by ITT for the Armed Forces can transmit as many as 100,000 telephone messages *simultaneously!*

Telephone Exchanges in the Sky

Now a miniaturized type is to be produced by ITT Components Division—small enough for satellites, where its amazing message capacity could be utilized to relay *thousands* of dial telephone calls to points around the globe.

ITT traveling wave tubes of many sizes are already in use in major areas of telecommunications, and in radar, missile guidance, electronic countermeasures, microwave radio, and television.

Pioneers in Electron Tubes

ITT Components Division, backed by experience almost as old as the electron tube industry itself, also manufactures *Iatron*® tubes that can display information, store it for days, erase it at will; photo multiplier tubes that convert light into an electrical signal and amplify it millions of times; image converter tubes for infrared applications, and tubes that give sharp eyes to our radar warning systems.

Other ITT tubes include types for industrial power, rectification, and radio-TV broadcast transmission.

In the free world today, nine ITT System companies are developing and building electron tubes for hundreds of essential and sophisticated tasks—in laboratories, industry, global communications, and national defense. For information, write ITT Components Division, Clifton, New Jersey.

giving the "breath of life" to solid propellants!

TRONA® ...first and foremost source of supply for **AMMONIUM PERCHLORATE**

Advances in solid propellant technology have depended on AMMONIUM PERCHLORATE from American Potash & Chemical Corporation since the very beginning. First in the field with this essential oxidant, AP&CC was for many years the only domestic producer of ordnance-grade NH_4ClO_4. Today, with a growing network of strategically located plants and increased technical knowledge, Trona still leads the industry. Supporting the big tonnage production of AMMONIUM PERCHLORATE at Henderson, Nevada is the new SODIUM CHLORATE plant at Aberdeen, Mississippi, making AP&CC the free world's largest producer of $NaClO_3$. If a guaranteed source for AMMONIUM PERCHLORATE and the very latest in technical developments, gained through years of experience in this field, are important to your process and products, contact your nearest AP&CC sales office today.

CW INTERCEPT RADAR

Continuous Wave Airborne Intercept Radar is superior to pulse radar for detecting low-flying targets. Even using special techniques, pulse radar echoes from low-flying targets are obscured by ground clutter. However, the unique character of Doppler-shifted frequencies distinguishes the target signal from ground clutter.

The intercept radar locks on and tracks the target Doppler frequency by means of an automatically positioned narrow bandpass filter. This bandpass filter also rejects most of the noise, clutter, false signals and interference, thereby assuring top system performance.

This CW intercept radar is one of the many interesting developments engineered in Raytheon's Maynard Laboratory.

PROFESSIONAL ASSOCIATION WITH A FUTURE

Raytheon has excellent openings for qualified engineers and physical scientists with BS or advanced degrees. Positions are available in systems, development, design or manufacturing engineering of complex electronic equipments. Please write Donald H. Sweet, Government Equipment Division, Raytheon Company, 624 Worcester Rd., Framingham, Mass.

NOTABLE ACHIEVEMENTS AT JPL...

PIONEERING IN SPACE RESEARCH

Another important advance in man's owledge of outer space was provided Pioneer III. This, like many others of a ntinuing series of space probes, was signed and launched by Jet Propulsion boratory for the National Aeronautics d Space Administration. JPL is admin- tered by the California Institute of chnology for NASA.

During its flight of 38 hours, Pioneer III was tracked by JPL tracking stations for 25 hours, the maximum time it was above the horizon for these stations.

The primary scientific experiment was the measurement of the radiation environment at distances far from the Earth and telemetering data of fundamental scientific value was recorded for 22 hours. Analysis of this data revealed, at 10,000 miles from the Earth, the existence of a belt of high radiation intensity greater than that observed by the Explorer satellites.

This discovery is of vital importance as it poses new problems affecting the dispatch of future vehicles into space. The study and solution of such problems compose a large part of the research and development programs now in extensive operation at the Laboratory.

Armco PH Stainless Steels—
PH 15-7 Mo
17-7 PH
17-4 PH

New steels are born at Armco

These special Armco Stainless Steels, developed specifically for aircraft and missiles, are used for missile airframes, tanks, power plants and accessories because they:

- possess high strength-weight ratios up to 900-1000 F.
- can be readily fabricated by standard methods.
- resist corrosion without plating or painting.
- are commercially available in all forms.
- can be hardened by simple heat treatments.
- have been proved by performance.

For complete information on the properties and fabrication of Armco's Precipitation-Hardening Stainless Steels, write to Armco Steel Corporation, 1499 Curtis Street, Middletown, Ohio.

FORD MOTOR COMPAN
DIVISION–AERONUTRONI
FOR TH

Ford Motor Company,

THE AMERICAN ROAD
DEARBORN, MICHIGAN

We are pleased to announce the establishment of a new division of Ford Motor Company.

On July 1, 1959, Aeronutronic Systems, Inc., a subsidiary, will be merged with the Company, and its operations will be carried on by Aeronutronic, a Division of Ford Motor Company.

Aeronutronic was organized in 1956 with the goal of large-scale participation in the nation's space and missile programs. Over the past three years, the subsidiary has achieved an excellent reputation and record of accomplishment and we are happy to welcome the new operating end-product division of the parent company.

As a division of the company, Aeronutronic will continue to have as its objective the development and manufacture of advanced technical products for both military and commercial purposes in the areas of weapon systems and space systems, missile range systems and instrumentation, advanced electronics, data processing systems and computers.

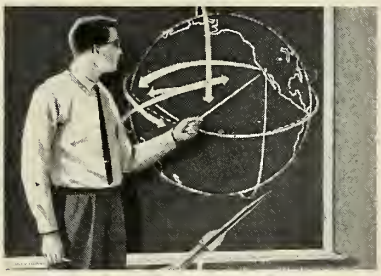
The merging of Aeronutronic into Ford Motor Company will permit more effective Company support of Aeronutronic programs and thus facilitate the undertaking of more extensive projects than have been feasible in the past.

Ernest R. Breech
Chairman of the Board

Henry Ford II
President

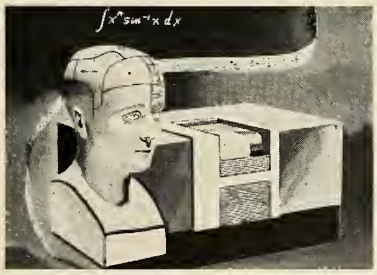
AERONUTRONIC – MEETING THE REQUIREMENTS OF

missiles and rockets, July 20, 1

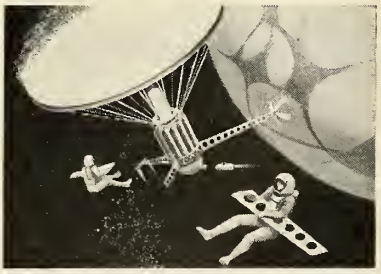


NNOUNCES A NEW
PECIALIZING IN PRODUCTS
PACE AGE

NEW 200-ACRE ENGINEERING AND RESEARCH CENTER. An artists' concept of Aeronutronic's new 20-million dollar Research Center under construction at Newport Beach in Southern California. Here, Ford resources provide the finest facilities for carrying out complete engineering, research and prototype manufacturing operations on advanced projects. Over 40 government and commercial programs are now underway at the new Center and at other Aeronutronic facilities nearby.



OFFICE OF ADVANCED RESEARCH. Basic research is conducted in areas of long-range company interests, with special emphasis in the fields of atomic and molecular physics, physical chemistry and atmospheric physics.



RANGE SYSTEMS OPERATIONS provides total capability to study and plan missile range instrumentation and to staff and manage complete missile range operations for U. S. military and civilian agencies.

AL WEAPON SYSTEMS OPERATIONS. The of TWSO is to research, develop and ucture tactical weapons for the military ics. Under development now is the Army's lion SHILLELAGH surface-to-surface missile system.

COMPUTER OPERATIONS is engaged in research, development, manufacturing and marketing of computer components and communications systems for military and commercial use. New products developed are revolutionizing present data processing techniques.

SPACE TECHNOLOGY OPERATIONS is devoted to solving problems dealing with man's new frontier. Typical development programs include satellite communication, ICBM detection, space vehicle design and research rockets, such as Project Far Side.

For information regarding interests, ilities, products or positions, write to Aeronutronic, a Division of Ford Motor Company, oad, Newport Beach, California.

Van Allen Discovery Most Important

U.S. has obtained more fundamental scientific information from its satellites than the USSR from its instruments in heavier payloads

RBITS OF trapped particles, from the paper published by oermer in 1913: Orbit A shows a particle injected into the diation belt at a large angle to direction of the local magtic field; Orbit B, particle injected at small angle. (Fig. 1)

INNER AND outer radiation belts in space. Outer belt penetrates into the atmosphere at the latitudes of the auroral zones. Zones are indicated by light bands across the surface of the earth. (Fig. 2)

by Dr. Robert Jastrow

WASHINGTON—The first step toward e exploration of space occurred apoximately 22 months ago as a part of ie International Geophysical Year. In ie short interval since October, 1957, te new tools of research, the satellite d the space rocket, have produced o unexpected results of fundamental ientific importance.

First, instruments placed in the *Exprer* satellites by James A. Van Allen lve revealed the existence of layers energetic particles in the outer atmosphere. This discovery constitutes the most significant research achievement of the IGY satellite program. The layers may provide the explanation for the aurora and other geophysical phenomena, and they will also influence the design of vehicles for manned space flight, whose occupants must be shielded against their harmful biological effects.

Second, the shape of the earth has been determined very accurately with the aid of data from the first *Vanguard* satellite. As a result of this investigation, we have found that our planet tends toward the shape of a pear, with its stem at the North Pole. This discovery may produce major changes in our ideas on the interior structure of the earth.

Each of these discoveries was made with the aid of a U.S. satellite having a payload with a weight of approximately 10 pounds. It is a remarkable fact, and to the credit of the scientists responsible for the design of these small satellites, that they could be constructed to yield so much information per pound of instruments. It can be reasonably stated that we have obtained more fundamental scientific information from our satellites than the U.S.S.R. from its instruments, and on a per pound basis our yield of information has been amazing.

Of course, this is not to say that we could not have done even more in this first stage of space exploration, if heavier satellites had been available.

In addition to these two results of greatest fundamental importance, both the U.S. and the U.S.S.R. space research programs have also yielded other interesting data on the properties of the ionosphere and on the density and tem-

About the Author

Robert Jastrow, 33-year-old geophysicist and nuclear theorist, is chief of the Theoretical Division and chairman of the Lunar Explorations Working Group of the National Aeronautics and Space Administration.

Jastrow, who was graduated from Columbia College at the age of 18 and won his Ph. D. at 22, has lectured in physics at Columbia, Cooper Union, Leiden (the Netherlands), California, Yale and Maryland universities. He has been a member of the Institute for Advanced Study at Princeton, N.J., and consultant to the U.S. Naval Research Laboory, the Convair Division of General Dynamics, and the Los Alamos Scientific boratory. Jastrow joined NASA in 1958.

what are the particles? . . .

perature of the upper atmosphere.

• **Trapped particles**—The discovery of an intense zone of radiation in the outer atmosphere was first reported by Van Allen and his collaborators at the State University of Iowa on May 1, 1958. at a meeting of the National Academy of Sciences in Washington. Van Allen's results were confirmed by *Sputnik* data released by the U.S.S.R. at the Moscow IGY conference early in August, 1958. The zone discovered by Van Allen is commonly called a radiation belt, but the term is a misnomer because it is really a belt of particles rather than radiation.

We shall begin with a few remarks on the general features of the Van Allen particles. They are known to be electrically charged (probably a mixture of electrons and protons), because their intensity follows precisely the shape of the earth's magnetic field. A magnetic field acts on charged particles, but it does not have an effect on neutral particles and radiation.

Also. we know from a great deal of theoretical research, going back to papers published by the Norwegian physicist Stoermer a half century ago, that charged particles can be trapped in the earth's magnetic field in orbits in which they spiral about the lines of magnetic force, traveling back and forth between the north and south magnetic poles. Fig. 1 shows typical orbits of trapped particles, reproduced from the original paper which Stoermer published in *Videnskapsselkapets Skrifter* in 1913. The particles can stay in these trapped orbits for very long times, perhaps as long as several years if they are at altitudes of one thousand miles or more. The trapped particles are injected into the outer atmosphere at an exceedingly slow rate, but because they stay there so long the *total number* of particles in the atmosphere will still build up to very large values. That is the key to the formation of the Van Allen layer.

The *Pioneer III* space rocket showed that the layer actually consists of two separate zones, as shown in Fig. 2. Each zone contains particles with energies varying from approximately 20,000 to several million volts or more. There may be an appreciable number of particles at still lower energies, but these could not have been detected with the instruments flown thus far.

It is found that the particles only appear in appreciable numbers above 200 miles in the northern latitudes and above 600 miles over the equator, and have a maximum density of about 1 per cubic centimeter. However, the Russians have reported *Sputnik III* results which suggest that in or near the auroral zone, the outer belt may reach a density of 100 particles/cm at an energy of 10,000 volts.

• **Protons or electrons?**—The component at the lower energies probably consists of electrons. The more energetic particles are protons or a mixture of protons and electrons. In the inner zone, the penetrating particles have been definitely identified as protons with energies up to one billion volts, according to the results of an emulsion experiment recently conducted by White and Freden of the Livermore laboratory. The concentration of energetic particles is greatest in the inner zone, but is still only 0.1 per cent of the density of soft electrons in that zone.

The inner zone is peaked at an altitude of 2500 miles. The outer zone has a maximum at an altitude of 10,000 miles, and extends into space to a distance of approximately 35,000 miles from the center of the earth.

Until recently, we did not know the mechanism that produced the two zones. This problem of the origin of the zones was the subject of a very lively debate, marked by high atmospheric temperatures, at a recent conference sponsored by the NASA Theoretical Division. However, it is now believed, on the basis of a preliminary report by Van Allen on the *Pioneer IV* results, that the outer layer is produced by particles coming from the sun. The surface of the sun boils and bubbles in a very active manner, occasionally emitting large gusts of plasma or charged particles into the solar system. The *Pioneer IV* flight came immediately after 5 days of continuous and unusually intense solar activity of this sort, *and showed radiation intensities in the outer zone which were many times greater than those measured in the* Pioneer III *space rocket*. The *Pioneer III* flight had occurred in a time of solar quiet. The difference between the radiation levels measured in the *Pioneer III* and *IV* flights definitely establishes that the outer zone is fed by particles from the sun.

It is not yet precisely clear how the outer zone is built up by the solar streams. It may consist of the actual solar particles which have been trapped near the earth by the geomagnetic field, or it is possible that the sola stream produces the trapped particle indirectly by collisions with air atom The NASA schedule of rocket an satellite launchings includes exper ments which will indicate which c these theories is correct.

• **Cosmic ray reflection?**—The caus of the inner zone has not yet been de termined, but the available theoretic evidence indicates that at least som of the particles in this belt are produce by the beta decay of cosmic ray neu trons, as suggested by Christofilos, b Singer, and by the Soviet physici Vernov. The observations by Frede and White also support the hypothes that the inner belt is produced by co mic rays. The Freden-White data i dicate that the number and energ distribution of the energetic proto are in good agreement with what w expect from the beta decay of fa neutrons.

The presence of a gap between th two zones still presents a serious prol lem. On the hypothesis of beta-deca for the inner zone and a solar orig for the outer zone, we would expe the inner zone to rise smoothly in the outer, and it is difficult to expla the finding of a minimum in radiatic intensity between the two. In this co nection an interesting suggestion w made at the NASA conference by D Dessler of the **Lockheed Missile ar Space Division,** who pointed out th there is an irregularity in the geoma netic field which may be described a hole or depression in the magnet contours. He pointed out, further, th the lines of force passing through th irregularity are located at the positi of the gap between the zones. Wh particles are trapped on these lines force in the magnetic field they desce to lower altitudes than would be t case in a perfect dipole field. At t lower altitudes they pass through denser atmosphere and are rapidly moved from the radiation zone.

• **Geophysical effects**—As Fig. 2 i dicates, the particles in the outer zo are funnelled into the Arctic and A arctic by the concentration of the ma netic field near the north and sou poles. The outer zone dips down ir the atmosphere in these regions a disturbs the normal conditions whi exist at other latitudes. Two examp will indicate the consequences of t interaction between the trapped p ticles and the atmosphere.

First, we are rather certain that t *aurora borealis* and the *aurora aust lis* result from the excitation of t Arctic and Antarctic atmospheres collisions between air atoms and particles trapped in the outer zone.

Second, the trapped particle zo

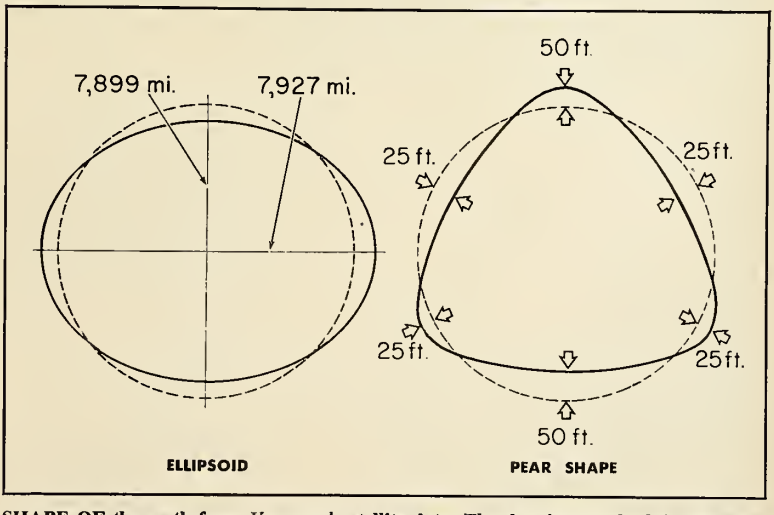
xplain the recent surprising discovery hat the air at high altitudes is warmer n the arctic than in the temperate ones. This discovery was made by the nalysis of experiments performed in .S. rockets at the White Sands missile nge in Arizona, and at the Fort hurchill range in the Canadian Arc-c. The rocket measurements indicated hat at altitudes above between 90 and 40 miles the air over Fort Churchill as a temperature of approximately 000°F., as compared with a relatively ool 2000°F. over Arizona.

We can understand these tempera-re differences as a result of heating oduced by collisions between the apped particles in the outer zone and e atoms and molecules of the upper mosphere. The Van Allen data, sup-emented by *Sputnik III* results and rocket measurements performed by e Naval Research Laboratory and the ate University of Iowa, provide opportunity to make a quantitative st of this heating mechanism. With e aid of the rocket and satellite data, Harris of the NASA Theoretical Di-sion and the author have carried out lculations that show that collisions th the Van Allen particles must use an increase of several thousand grees in the temperature at the cen-r of the auroral zone, in qualitative reement with the observations.

Thus we see that the trapped par-le layers provide the explanation for a number of geophysical phenomena. is this geophysical significance of the apped particles that makes their dis-very so important to fundamental search.

• **Radiological hazard**—The trapped rticle layer has an additional signifi-nce for space technology in that it ay constitute a serious radiological zard to the personnel of future man-d space flights. In order to determine e biological exposure level produced the layer, we must know the ener-s of the trapped particles, and ether they consist of electrons, pro-ns, or heavier particles. Detailed swers to these questions should be ovided in the future by further ex-riments now in preparation. The ta available at present tell us only t the exposure levels appear to be hin the range from 2 to 50 roent-gs for personnel in a vehicle passing ough the atmosphere to the moon outer space. These levels are far ow the estimated lethal dosage for mans, and they can be further re-ced by body shielding. This problem y not be a major one in comparison h other uncertainties of the first ce flights.

Of course, the exposure can be ch greater for personnel in a man-ned orbiting satellite. It may in fact be necessary for the early manned satellites to remain at low latitudes and relatively low altitudes, below 400 miles, where the intensity of the radiation belt is sharply reduced.



• **Shape of the Earth—1958**—*Beta 2*, the first *Vanguard* satellite, was launched on March 17, 1958. Later in 1958, O'Keefe, Eckels, and Squires, three scientists in the Theoretical Division of the NASA Goddard Space Flight Center, recognized certain changes in the perigee height of the satellite (orbital point closest to the earth) that were contrary to the established theory on the shape of the earth. This theory maintained that the earth had the shape of nearly perfect sphere, flattened somewhat at the poles, and bulging at the equator by about 12 miles as a result of the outward centrifugal force produced by the rotation of the earth. If the "flattened sphere" theory were correct, the force of gravity on the satellite would be the same in the northern and southern hemispheres. Actually, the orbit was found to be different in the northern and southern hemispheres. This indicated that the earth was not symmetrical above and below the equator as previously indicated.

The new findings show that the sea level at the north polar cap is raised by about 50 feet above what has been considered normal. At the solar polar cap there is a depression of 50 feet in the sea level. There are also small changes of the sea level in the temperate zones. The combined effect of these variations is to give the earth a tendency toward the shape of a pear, with the narrow end in the Arctic and the broad base in the Antarctic. A schematic representation of the old and the new shapes is shown below in Fig. 3.

This result is not entirely new. Without indicating his reasons, Columbus stated in the 15th century that the earth must be pear-shaped, as the following quotation proves: ". . . that it is not round in the way they have written, except that it has the shape of a pear that is very round, except where it would have a stem, where it is higher . . . " (Henry Vignaud, *Histoire Critique de la Grande Entreprise de Christophe Colomb*, Paris, H. Welter, 1911.)

A 50-foot variation seems insignificant in comparison with the 4000-mile radius of the earth, or even in comparison with the 12 mile difference between the polar and equatorial radii. However, this change means that there is an excess of matter near the North Pole, or a deficiency at the South Pole, sufficient to draw up the level of the sea by 50 feet *over an area the size of the Atlantic Ocean*. Such variations in the distribution of mass imply very large shearing forces in the interior of the earth.

We may ask what can be the cause of the pear shape. That is not known, but we can make some interesting guesses. For example, we know that the earth is currently growing warmer. It is possible that the Antarctic ice cap has been decreasing in thickness faster

SHAPE OF the earth from *Vanguard* satellite data: The drawing on the left represents the old conception of the spheroidal earth, with a 26 mile difference between the diameters at the pole and the equator. The figure on the left shows, in exaggerated form, the effect of adding a pear-shaped component to the ellipsoid, as required to fit the *Vanguard* data. In both drawings dashed circle represents an equivalent spherical earth with equal volume. (Fig. 3)

shape of geoid established . . .

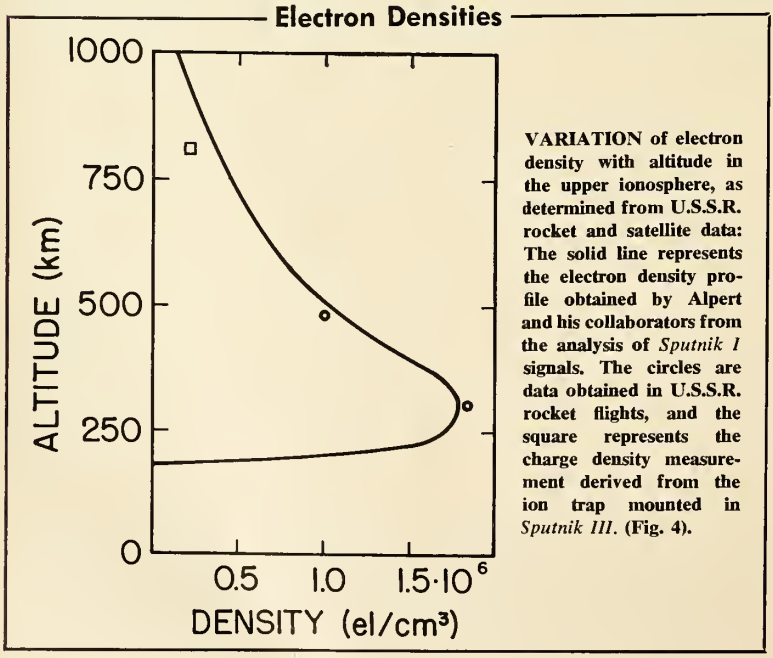
than the earth beneath can bounce back beneath the reduced load. That would account for the depression at the base of the pear.

The above result indicates that the interior of the earth is not as plastic as originally assumed. NASA scientists have in fact concluded that a mechanical strength at least as great as that of a brick wall is required to support the dome in the north and the variations in the southern hemisphere.

• **Ionosphere properties**—The U.S.S.R. satellites have been the major source of ionospheric information thus far, primarily because these satellites transmit on the relatively low frequencies of 20 and 40 megacycles.

Low frequencies are poor for tracking purposes because the signals are bent by the electrons in the ionosphere during the course of their passage from the satellite to the ground tracking stations, producing an error in the apparent position of the satellite. At 40 megacycles the ionosphere produces an average error of 6 miles in the position of a satellite 600 miles from the observing station.

However, the bending that adversely affects the low-frequency signals for tracking purposes can provide valuable data on the state of the ionosphere, provided the true position of the satellite is known at all times. For example, the difference between the true position and the apparent radio position depends on the number of atmospheric electrons in the path of the signal from the satellite to the observing station. This effect has been used by several scientists to measure the electron density in the ionosphere. The true position can be determined by optical methods if the satellite is sufficiently large. Otherwise it can be done by combining a large number of radio observations for improved accuracy.



The U.S.S.R. satellite, *Sputnik I*, is a particularly intriguing satellite for ionospheric studies because it transmitted signals on both 20 and 40 megacycles for an extended period. Excellent worldwide recordings were obtained on both frequencies during the radio lifetime of this satellite. The ionosphere physicists must know the true position of *Sputnik I* in order to extract scientific information from these records. Thus far the U.S.S.R. has unfortunately not furnished any detailed information on the orbits of *Sputnik I* or the other Russian satellites, although requests for this information were made in 1958 at the IGY conference in Moscow.

• *Sputnik* **ephemeris**—In the absence of orbit information from the U.S.S.R., the Theoretical Division of NASA has collected all available radio observations and combined them to produce an ephemeris, or table o true positions, for *Sputnik I*. Thi ephemeris has an accuracy of only te kilometers in the position of the satel lite, but it is the best one available t American and European scientists a the present time. The NASA ephemeri for *Sputnik I* is being made available t all scientists in the U.S.A. and in othe countries.

The Moscow IGY conference in cluded a Soviet report on ionospheri investigations, based on undisclose U.S.S.R. orbit data. Prof. Alpert of th University of Moscow gave the result of an analysis of the *Sputnik I* signals which indicated that the upper layer o the ionosphere extends to much highe altitudes than had been anticipated Alpert found the very important resul that the number of electrons above th level of maximum density in the iono sphere is 3.5 times greater than th number below the maximum. The elec tron density profile obtained by Alper is shown in Fig. 4, together wit U.S.S.R. rocket data. The Alpert profil appears to be a reasonable representa tion of ionospheric densities unde average conditions.

The third U.S.S.R. satellite, *Sputni III*, has also yielded interesting iono sphere results obtained from a devic called the "ion trap." The ion trap i a spherical collector approximately 1 inches in diameter, attached to the sur face of the satellite by an extendin rod 30 inches long. A negative voltag is placed on the trap, drawing all near by positive ions to it. The rate at whic the ions are collected is telemetere automatically to the ground, and pro vides a measurement of the number o positive ions in the neighborhood o the satellite.

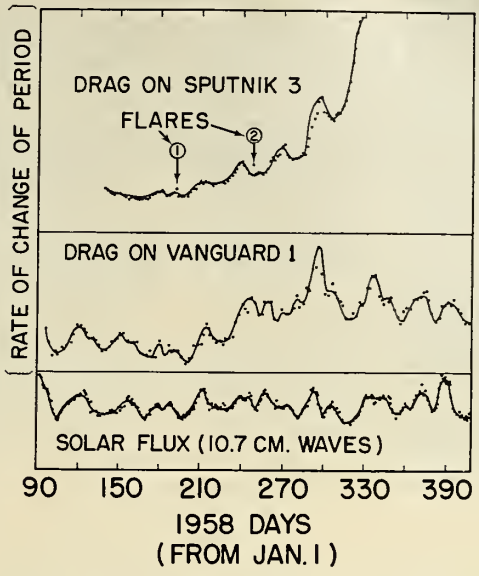
A few samples of the ion trap dat were presented at the Moscow con ference. They indicated that the io density values are in reasonable agree ment with the electron densities meas ured by Alpert, as shown in Figure 4 As a by-product of the experiment, th ion trap also showed that *Sputnik II* acquired an appreciable negative charg in its passage through the ionosphere corresponding to negative potentials o several volts. An investigation by scien tists in the NASA Theoretical Divisio indicates that a satellite can be charge to still higher potentials, on the orde of thousands of volts, in those parts o its orbit that extend into the region o the great radiation belt. An extensio of the calculations published in 195 by C. A. Pearse and the author show that if the satellite is charged to kilo volt potentials, it will be slowed dow

VARIATION of electron density with altitude in the upper ionosphere, as determined from U.S.S.R. rocket and satellite data: The solid line represents the electron density profile obtained by Alpert and his collaborators from the analysis of *Sputnik I* signals. The circles are data obtained in U.S.S.R. rocket flights, and the square represents the charge density measurement derived from the ion trap mounted in *Sputnik III*. (Fig. 4).

y an electrical drag force which is 10 100 times greater than the ordinary erodynamic drag.

• **Density and temperature**—Direct easurements of the density of the atosphere have been made by installg ionization gauges in rockets. These easurements extend to an altitude of 50 miles. For altitudes above 150 iles the density has been measured inrectly, by analysis of satellite orbits. he indirect measurements depend on e fact that the atmospheric drag rces acting on the satellite are proortional to air density. The drag forces use a decrease in the energy and erefore in the period of revolution of e satellite, which can be easily meased and analyzed to give the average r density in the orbit.

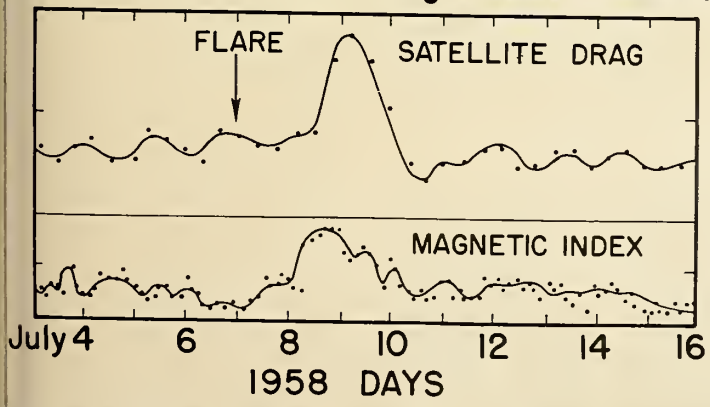
The striking feature of the latest cket measurements of density is their eat variability with time of day, sean and latitude. The data show that an altitude of several hundred kiloeters the upper atmosphere is two hes heavier in the day than at night, d two times heavier in the summer hn in winter. During a summer day arctic latitudes, where the "day" lasts rarly 24 hours, the density is four to ht times greater than the density at e same time in the temperate zones.



There appears to be a simple exnation for all of these effects, rmely, that prolonged exposure to the sn heats the atmosphere and causes a upward expansion, producing very ge relative increases in the thin air a high altitudes.

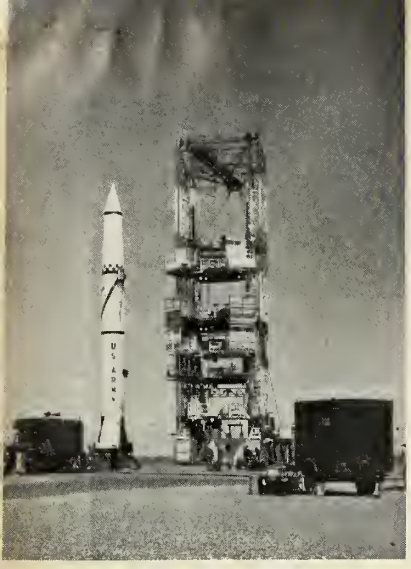
• **Satellite drag variations**—The satite density data also show large fluctitions in addition to the systematic riations described above. These fluctitions are probably the result of atospheric heating produced by streams o energetic particles and radiation m the Sun. Dr. Jacchia of the rvard Observatory has in fact discovered that the apparently random fluctuations are actually proportional to the changes in the intensity of the 10-centimeter radiation from the sun, which constitutes an excellent measure of solar surface activity. The correlation between the satellite drag and solar flux is shown in Fig. 5.

Jacchia has been able to eliminate electromagnetic radiation as the source of the drag variations, and has succeeded in identifying the heating effect with the arrival of corpuscular streams in the vicinity of the earth, following major solar flares. The proof of this result is shown in a report recently published by Jacchia in *Nature*. Fig. 6 shows that the drag increases observed after two solar flares did not occur at the time of the flares, but began approximately 1 day later at the same time that the magnetic K index spurted upward. A rise in the K index signifies the onset of a magnetic storm, and therefore the arrival of the relatively slow-moving solar corpuscular stream which accompanies the flare.



This beautiful demonstration of the relation between upper atmosphere properties and solar corpuscular streams promises to open a new chapter in the study of solar-terrestrial relationships. I believe that in retrospect it will turn out to be one of the most significant results to come from the IGY satellite program.

Solar Effect on Satellite Drag



CORRELATION between solar activity and satellite drag. In the graph satellite drag is plotted on the same base with the observed flux of solar radiation in the 10 centimeter region of the spectrum. The 10 centimeter radiation is an accurate measure of solar activity. The figure demonstrates a perfect correlation of maxima and minima in the two curves. (Fig. 5).

Drag Increase with Storms

CORRELATION of drag increases with magnetic storms, following a major solar flare: The time of occurrence of the flare is indicated by an arrow. The onset of the magnetic storm, which signifies the arrival of corpuscular streams from the sun, is marked by the increase in the magnetic index plotted from the lower graph. (Fig. 6).

SERVICE tower for *Redstone* at White Sands.

Missile Support Progress . . .

Bigger Vehicles Will Pose More Baffling Engineering

Solution to missile support problems largely rests with Army's Corp of Engineers which has lion's share of responsibility

WASHINGTON—The art of launching a rocket has reached such refinement that the supporting mechanisms and structures required to get our exotic birds off the ground present the most baffling of engineering problems.

The solution of some of these support problems is a responsibility of the U.S. Army Corps of Engineers, headed by Maj. Gen. E. C. Itschner. As the Chief of Engineers explains it, the Engineers' role in the Government's missile and space program is a multiple one—performing a variety of missions for the Army Missile System; constructing missile bases for the Air Force; and carrying on construction projects for the Advanced Research Projects Agency and the National Aeronautics and Space Administration.

Working closely with the Army Ordnance Missile Command, the Corps of Engineers' support of guided missile and rocket operations includes the provision of Engineer troops; construction of missile sites, test laboratories, training centers and other facilities needed to train men and develop weapons; supply and maintenance of engineer equipment and material; provision of maps and geodetic data; and development by research; often in cooperation with industry, of new engineer equipment for the Army's family of missiles.

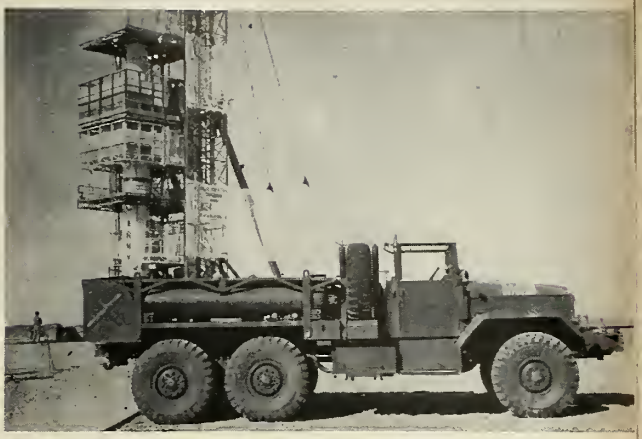
• **Keeping abreast**—All of these areas of support are equally important to the Army missile program, Gen. Itschner said, but to those whose interests lie primarily in keeping abreast of new developments in the constantly changing requirements of the program, a review of the research efforts of the Corps is in order. These efforts affect all Army missiles, from the operational *Lacrosse* to the still-to-be tested *Pershing*, successor to the *Redstone* family.

"Nuclear warfare will impose a requirement for great mobility on our ground forces, which must have the capability of hitting the enemy, then dispersing and regrouping again for another strike where it is least expected," Gen. Itschner explained. "We must be able to move our rockets and missiles into the battle area and out again on short notice. Supporting equipment, such as power generators, fuel tanks, fire control vans and radar equipment must also be easily and quickly moved. To attain this mobility, the Corps is developing smaller and lighter equipment which will do the job for which a particular missile has been designed.

"For example, the presently avai able conventional engine generat capable of providing power r quired for guidance of the *Lacros* missile weighs 900 pounds with a cessories. Since it is necessary th this generator be manpacked to t forward observers' position, we a developing a generator of 3 KW ou put, 400 cycle with precise pow regulation capable of being carri by one man, or with a full fu tank, by two men. The **Curtiss-Wrig Corporation, Santa Barbara Divisio** developed and demonstrated enginee ing models in sixteen months. One the unusual engineering characteristi of this generator is the silencing fe ture. Operational noise from this equi ment will not be heard further than few hundred feet.

"Also under development is t power pack for the *Pershing* miss system. This pack is a combination utilities ordinarily furnished by t Corps of Engineers as separate piec of equipment. The various units a packaged on one base plate, with lit greater total weight than is norma found in any one of the componen Electric power of three different outp characteristics, high pressure air (30 psi), and conditioned air all generat from one gas turbine drive, are cluded for a total weight of abo 2600 pounds. This unit will be tra ported on a vehicle weighing 95 pounds which also mounts a fire co trol hut. The standard air compress of the size needed, three generato and an air-conditioning plant heati unit, with four vehicles previously quired to transport them, would wei upwards of 28,000 pounds."

• **Interservice cooperation**—Of vi



About the Army Engineer Chief

Maj. Gen. Itschner has charge of the booming missile construction program for both the Army and Air Force. In addition, he is responsible for the Corps' nationwide civil functions. A graduate of West Point (1924) and Cornell, the General has served in Army construction projects all over the world—Europe in WWII, the Philippines, and Korea. Known as a "man in a hurry," his major responsibility now is directing construction of the new Air Force ICBM bases along with a whole range of missile research and development, testing, and launching facilities, including the Army's Nike bases.

IYDROGEN peroxide service truck is part of support equip-ıent for *Redstone*.

BIG TASKS are performed by vehicles in missile support. Representative is this 5000-lb compressed air storage tank.

enefit to the Army in speeding the evelopment of the *Pershing* system is ıe precedent established by having one chnical service participating directly ı the program of another, the Chief f Engineers said. Specifically, the ower pack is being developed by the **Martin Company,** contractor for de-elopment of the missile system for the rdnance Corps, Army Ballistic Mis-le Agency, and the Engineer Research nd Development Laboratories (ERDL) ho serve as technical supervisor of the ack development for the ABMA, op-rating within the framework of the rime contract.

"Again, in the high power acqui-tion radar (HIPAR) building for the nproved *Nike-Hercules*, as in the *ershing* power pack, we have an in-grated Engineer-Ordnance working elationship," Gen. Itschner pointed ut. "ERDL is the technical super-isor for the Army Rocket and Guided lissile Agency for the development f a pre-fabricated building to house new radar. It is evident that the rmy will gain from this joint opera-on in both the development and logis-cs stages. Experience gained by the orps of Engineers from participation development will enhance our capa-lity for providing spare parts and aintenance support of the resulting roduction item."

In the HIPAR building, where mo-lity and weight are of prime im-ortance, the unique engineering prob-m is in retaining the necessary air-ght panel seal despite repeated as-mbly and disassembly of the build-g, a problem not heretofore involved prefabricated building. Inflated seals e being used at all joints, and it ppears possible that a technical break-through in this particular problem area may result, the General disclosed.

Another development item with a requirement for high performance and low weight is the air-conditioner—heater plant for an Army field missile. This plant, a unit weighing 350 pounds, provides 38,000 BTU of air-conditioning and approximately 35,000 BTU heating per hour. It will be used in a van or a shelter of a field battery control center. Two difficult engineering problems—vibration and noise level—were encountered due to the high rotating speeds of the motors and compressors. Both are being solved through unique packaging and insulating methods. Because of an immediate requirement for this unit, a six month development time was imposed. Production models are scheduled with an initial delivery time of nine months.

• **Skyscraper on wheels**—Recently, the design was completed for a 305-foot missile service tower to be built at Cape Canaveral for the Advanced Research Projects Agency space vehicle, the *Saturn*. (MISSILES AND ROCKETS, June 8, 1959.) The tower, as tall as a 28-story building, will be on wheels.

Another ARPA project at Redstone Arsenal, is a static test tower being modified for use with the *Saturn*. This is the Army Ballistic Missile Agency's 140-foot tower previously used to test missiles up to the size of the *Jupiter*. Upon completion of the work, the tower will be capable of statically testing missiles having up to 1,500,000 pounds of thrust.

The work consists of driving approximately 6000 lineal feet of steel piling, constructing two reinforced concrete underground anchors 61 feet below bedrock and erecting approximately 470 tons of structural steel to be used for mounting the hold-down devices for the missile test. A cantilevered 100-ton bridge crane and hoist will be erected atop the modified structure for lifting the missiles and equipment into test positions.

Another missile service tower, fabricated by the **Noble Co.,** Oakland, Calif., is under contract with ERDL and scheduled for erection at Cape Canaveral in July. It is a mobile structure 150.25 feet tall, composed of twin towers mounted on a rubber tired trailer 42½ feet long. The tower has a traveling crane on top and is designed to handle *Jupiter* and *Redstone* type missiles. When servicing of the missile is completed, the tower moves away on its own trailer.

As missiles become more sophisticated, the demand for purer fuel becomes more urgent, Gen. Itschner said. The Ordnance Corps has determined the maximum allowable hydrocarbon count as .03 parts per million in the liquid oxygen as it is pumped into a missile such as the *Redstone*, largest field operational weapon of the Army. There must, therefore, be frequent purity checks by the soldier missilemen of the Engineer unit charged with supplying the fuel. To meet this requirement, ERDL is pursuing a project for developing a test instrument that can be easily used by the engineer soldier for checking the purity of LOX with a maximum of accuracy and a minimum of danger. Another field instrument under development by ERDL is for checking the dew point moisture content of compressed air at temperatures as low as –85 Fahrenheit.

• **Storage problems**—Loss of liquid

oxygen through evaporation during storage and transfer to the missile is another problem which plagues the Engineers. This loss, which now varies from 50 to 75 percent, is being reduced by improved equipment, especially fittings. ERDL is also developing a new type of storage container with unusual types of insulation. Inasmuch as LOX must be hauled from our mobile field generating plants to the launching sites in nine-ton tank trucks, the handling problem is a major one. Even though the Engineers have developed LOX plants with capacities of up to twenty tons per day, fantastic amounts are required to fuel a 70-foot missile. Heavy losses, particularly in the event of an actual combat situation, might cripple operations.

The Corps of Engineers' research and development work for the Army missile systems presently constitutes at least 25% of the research and development effort at ERDL. This work is being carried on both by ERDL personnel and by contract. It includes dozens of projects not heretofore mentioned, such as special air-transportable and mobile cranes, safety shower bath units to decontaminate personnel and clothing worn around toxic fuels, night vision equipment and special tools such as a welding machine for use on thin gauge materials. ERDL is even developing an unusually effective vacuum cleaner for cleaning the electronic and other delicate equipment used in the control vans.

Recently, the Corps completed an engineering analysis of the power requirements for the *Nike-Zeus,* including consideration of the remote stations where commercial power is not available. Transportation of fuel is a costly and often hazardous logistical effort. It has been determined that nuclear power plants can be designed to meet the stringent specifications required in operation of *Nike-Zeus* radar and electronic equipment. **Alco Products, Inc.,** which built the first Army power reactor plant at Fort Belvoir, Virginia, has completed a preliminary design and has been selected by the Army to complete the final plans of the proposed plant.

Missiles, regardless of whether they are Army surface-to-surface weapons or the Air Force's intercontinental ballistic missile, must be aimed at the target before they can be fired, Gen. Itschner noted. To attain the degree of accuracy needed to make missile warfare pay off in victory, the man aiming the weapon must know two things. First, he must know precisely where the missile is located at the time of launching, and second, he must know precisely where the target is in relation to the missile.

The task of locating targets and the guiding of the missiles to them is a complicated one requiring close coordination of the efforts of many men. Basically, it is a mapping job. The Engineers are responsible for providing the interconnected grids and earth measuring information necessary to direct longer range strategic missiles.

Said Gen. Itschner, "With the Air Force, we are working on the use of high altitude electronically controlled aerial photography to speed the compilation of maps, and we are using helicopters and geodimeters to accelerate field surveys. By using electronic digital computers, the time required for geodetic control adjustment has been reduced by years.

• **Where we are**—"Engineer teams on Pacific islands, using tracking devices, are obtaining valuable data from the *Vanguard* satellite as to precise island locations, which heretofore have been mistakenly located on maps from hundreds of meters to miles from their actual positions. This activity is helping us to get the answer to the question, 'Where in the world are we?'

"To help perfect methods of rapidly and accurately locating targets within a tactical area, which might be 200 miles deep on an atomic age battlefield, the Corps of Engineers is evaluating various target location systems. These involve the use of day and night aerial photography, radarscope photography to map the ground through clouds and darkness, and electronic systems to locate the photographic aircraft with respect to known ground stations."

A large part of the Engineers' efforts in construction are being directed toward the Army and Air Force missile programs. Construction of missile support facilities involves types and methods of building undreamed of a few years ago. Specifications now require construction tolerances which were possible before only as laboratory experiments.

"The *Zeus,* third generation of the *Nike* family, will create greater problems," Gen. Itschner predicted. This weapon is the Army's anti-missile missile designed to intercept enemy ICBM's in flight. The *Nike-Zeus* is a highly complicated system that brings the scientist, manufacturer and construction man together. Missile, test, and launching facilities are designed, developed, and built simultaneously. Flexibility will be the watchword at all times for those connected with the development of this missile. Constructors, designers and manufacturers will have to adapt themselves to the demands imposed by the rapidly widening knowledge being acquired by missile experts, for whom there seemingly are no limits except the horizons of their imaginations.

"Where these scientists and missile experts will take us in the space age is difficult to foresee at this point. The Army's Corps of Engineers, however, is preparing for whatever problems present themselves, whether they be on the moon or some fantastic reconnaissance space station on the route to Mars. Our Engineer research and development experts are conducting studies on space construction problems in sanitation, water supply, thermodynamics, electric power and advanced methods of prefabricated shelter construction. One of the programs considered important to the future involves a look into new sources of energy such as thermoelectric and thermionic generators and solar energy.

"The by-products of the research which our space program has brought about are leading us to portals of knowledge which are only now beginning to open for the benefit of mankind."

TWO IMPORTANT items for *Jupiter:* 100 KW power generator and vertical check-out shelter.

Fertile Field for New Applications

Microminiaturization, solid-state physics and communications technology are promising areas

by Robert J. Jeffries

DANBURY, CONN.—Whenever a new ientific fact is discovered, or when a w technology gains momentum, there a great tendency for authors and blishers to rush into print with a ultitude of predictions and projec- ns as to what the future will bring. areas already established there are e traditional articles on the "state the art" which appear periodically.

Both categories of exposition— e projections and implications of new chniques, and the periodic review established technologies—fill impor- nt functions. In general, they serve e needs of the "lay" public, as a basic ucational tool, and the practitioner the field, possibly as a stimulant, and rtainly, in the minimum, as a con- nient tabulation of the art, by means which he can mentally check his n progress and understanding.

Progress in Space Instrumentation ses a particularly difficult subject on ich to write an article for the read- of MISSILES AND ROCKETS Magazine. be correct, the author must define at he means by "Instrumentation"; must also define what he means by pace"; the meaning of "Progress" may take as self-evident. Also it obvious that the audience is not a y" audience in the sense of being technically unsophisticated in the subject, and lastly, for reasons of security, it is impossible to present an up-to-date review of the state-of-the-art in any detail.

What objective and means is there left then which justifies an article at all? The answer lies in perspective. If an article can present a situation in perspective in such a manner as to aid the reader in a better comprehension of his own role and problems, if it can stimulate the reader to a more creative synthesis of solutions to his problems, if it can direct attention to critical areas in need of attention and potentialities as yet unexploited, then it serves a useful purpose. In a modest way these shall be the objectives of this article.

• **What is instrumentation?**—Literally hundreds of efforts have been made over several years to define instrumentation. A synthesis of these several efforts, which in the least serves to define the scope of interests of this article is as follows:

"Equipment and techniques associated with and essential to the detection, measurement, transmission, translation and display of information, and including possible associated computation and utilization of the information for control purposes."

• **What is space?**—For purposes of this discussion, space may be defined as the volume around us excluding the earth, the oceans, and the atmosphere. Unfortunately, this definition tells us little, really, in that it assumes a precise definition of "atmosphere." One can define "atmosphere" as one chooses. For immediate purposes, let us assume as a purely arbitrary decision, that the atmosphere extends from the surface of the earth and its oceans to a height of 100 miles. Space then becomes the volume around the planet Earth, but external to a spherical shell 100 miles thick, surrounding the Earth. Obviously this definition is unique to the understanding and use of an earth-oriented creature.

• **What is space instrumentation?**—From the definitions above, it is apparent that Space Instrumentation embraces all the instruments that guide and control space vehicles, measure characteristics and performance of space vehicles and operate on and digest, display, and automatically react to the resultant information. It also includes the hardware and techniques of measurement of space and its contents. This is to say that Space Instrumentation embraces virtually every technique and piece of hardware designed to gather data in space or related to the gathering of that data. Space instrumentation is not generally understood to include considerations of propellants, propulsion or structures. But what of a nose cone? In some instances, a nose cone becomes, in itself, an instrument—detecting, and measuring directly and indirectly, meteoric dust, temperature, etc. All the above considerations demonstrate the necessity for an arbitrary agreement as to what shall be embraced by the term space instrumentation. For purposes of this discussion, space instrumentation is defined to include the following:

About the Author

Robert J. Jeffries is president of Data-Control Systems Inc., Danbury, Conn. A former assistant to the president of Daystrom Inc., Dr. Jeffries was president of the Instrument Society of America in 1957-58.

He has taught engineering at various universities and has been a consultant to all three military services, the National Bureau of Standards and numerous commercial firms. Jeffries is a founder and trustee of the Foundation for Instrumentation Education and Research.

small business to benefit . . .

• Instrumentation for measuring characteristics of space vehicles,

• Instrumentation for measuring characteristics of space and its contents,

• Instrumentation for communicating and displaying space data.

Measurements of temperature, acceleration, position, flow, stress, vibration, noise, etc. are commonly made today by means of a host of different transducers. These measurements will continue to be made in the years to come. This past year has seen a continuation of the long-term trend, in which transducers are becoming smaller, lighter, of higher frequency response and greater output. There is evidence of a renewed interest in variable-reluctance phenomena in transducers. Most transducers in use today yield analog output signals. There are coming to the fore an ever-increasing number of techniques, combined with conventional transducer principles, which yield digital output signals. The number of measurements which can be made with sufficient accuracy to justify the resolution of digital representation is still small. The advantages of reduced susceptibility to degradation of data in subsequent handling is currently the most important influence in the stimulation of digital techniques.

• **Terse messages**—Space engineers are employing techniques of predigestion of data in flight, with subsequent transmission of derived and statistical characterizations of phenomena. Probably the greatest incentive and utility of such techniques lie not in the inherent data analysis that occurs but in a reduction of the total information to be relayed to a remote point or points.

Solutions to several of today's problems will undoubtedly become operational in the next few years. For example, with the advent of transistor circuitry we can anticipate that transducer outputs will ultimately be adapted to current-input circuits, rather than voltage-inputs. In the near future, however, and before the above can come to pass, the present 0-5 volt input levels will begin to lose popularity. Signal-conditioners, that is amplifiers, and signal translators for modifying available transducer signals to adapt them to conventional standardized telemetry equipments will increase in number and complexity. Finally, the technology is forced to an entirely new approach based on the characteristics of solid-state circuitry. Low-level, solid-state computers will replace electromechanical devices and multi-channel amplifiers. Some prototypes of this type already exist.

A prime objective will continue to be the reduction in size of all equipment. Many components, such as voltage-controlled oscillators, are already approaching a situation wherein the connectors and junction boxes are as large as the components themselves. Further reduction in actual size of individual components does not appear to offer as much margin for improvement as do several other avenues. In the near future, one can expect high-speed, low-level commutation to reduce the space requirements of multi-channel systems. New multiplexing concepts will permit more efficient utilization of available power, thus reducing space requirements for RF components and space and weight in the energy source. For sustained flights, power "captured" in flight is already being used to reduce overall weight requirements. The present enthusiasm for digitized data, while justified in many instances, must be tempered with the sobering fact that in most applications digitization of data increases the space and weight requirements of the instrumentation equipment required for a given information capability.

The most important and exciting promise of the future for all types of flight instrumentation lies in the evolving techniques of microminiaturization. There can be no doubt that these techniques have the potential to reduce the size and weight of all flight instrumentation circuitry. Some equipment of this type is now in use. However, several fundamental facts stand out at this time: (1) Microminiaturization techniques, being relatively new, have not yet progressed to a stage, at which it is possible to achieve accuracies and stabilities comparable to conventional circuit techniques in reproducible units. (2) Microminiaturized circuits are essentially custom-made, with a high rate of failures, with complicated fabrication problems and large capital equipment requirements.

The manufacturers of space instrumentation hardware are, in the main, small businesses. This is so because of the rate of technological advance, the relatively small production runs involved, and the high premium on individual initiative and adaptability. As small businesses they are not able to undertake the basic research inherent to microminiaturized circuit development. For these reasons it is not to b anticipated that conventional *miniatur ized* standard flight instrumentation wil be replaced in the near future, for th bulk of space vehicle instrumentation with *microminiaturized circuitry*.

• **Measuring characteristics of spac** —The obvious questions asked first b any explorer of a new world are "What is present?", and "How much i there?" As we initiate our manned ex plorations of space we begin with thes elementary questions. It is almost cor rect to say we are in the Stone Age o space knowledge; we must first find ou whether the environment of this nev "space world" is hostile to our being We must first detect and measure, an later evaluate, the effects of such thing as radiation, meteorites, weightlessness etc. The fundamental problem is to de cide what we should be looking for Once the variables to be detected an measured are defined, then the appro priate hardware can be developed.

While we progress toward manne exploration of space, we learn muc from unmanned observation station Missiles in trajectory, satellites in or bit and balloon-borne stations affor us effective vantage points for view ing space from a new angle an without the distractions and interfer ences associated with an earth-boun observatory. Obviously, most of th measurements made on far-space fron any vehicle located in near-space mus be based on electromagnetic phenom ena—received, reflected, refracted, o absorbed. The sciences and techno ogies of astronomy, optics, chemic analysis and photometry, working wit the instrument technologists are no evolving the transducer hardware adapted to the near-space environmen Balloon-borne telescopes, spectometer star trackers, etc. are now familia items for work in near-space.

• **Instrumentation for communicat ing**—Telemetry is the all-inclusive wor used to embrace the concepts and hard wares involved in remote measure ments. In practice, one usually differ entiates among transducer, telemetry and display equipment. Telemetr equipment provides the communicatio links between the measuring tran ducers and the display equipment.

The prime objectives of currer telemetry development are improve accuracy, reliability, space and weig reduction. Improved resolution is po sible through pulse code technique (However, improved resolution do not necessarily mean improved accu acy.) Pulse-coded data can be relaye from point-to-point either by radio o wire with no theoretical degradatio of quality. This represents a distin advantage over transmission of data i

nalog form. If however, in a pulse-
ode system, the transmission bit rate
high, there is the possibility of lost
ts, ambiguities, and loss of synchroni-
ation. These must be accounted for in
ny evaluation of ultimate accuracy.

Size and weight reduction in the
verall telemetry system can probably
e best effected by employing new
stem concepts. Pulse-coded systems
ill almost certainly increase size and
eight requirements. The power and
pace requirements of pulse-code equip-
ent capable of transmitting several
hannels of high-frequency intelligence
ata today are much greater than the
rresponding analog system. Employ-
ent of RF links in the microwave
nds poses additional problems. The
ficiencies of transmitters in these
nds is relatively low. Compromises
ill be necessary to balance increased
formation-handling capability against
duced electrical efficiency. A recently
nounced heterodyne technique, which
rmits the superposition of several
andard analog multiplexes and the
multaneous transmission of very high-
equency intelligence over a single RF
nk, appears to hold considerable
omise for reduction of overall system
ze and weight.

The display of telemetry data poses
veral problems that are not solely
chnical. During flight, ground per-
nnel are aided by real-time informa-
on displays. During subsequent data
alysis much time and effort can fre-
ently be saved, if, instead of reduc-
g all available data, a quick search
n be made for "interesting" phe-
mena, and that portion of the data
spected minutely. Inasmuch as every
ght represents a large investment, it
desirable to process all available data
every conceivable way, usually prior
the next flight. In general, then the
splay problem is really three prob-
ms; (1) real-time quick-look, (2)
ta-reduction search and quick-look,
d, (3) detailed comprehensive data
duction. All three appear to be essen-
l to full and effective utilization of
e flight data. As intelligence frequen-
es go higher, as the number of chan-
ls of information increases and as
mmutation rates increase, new and
sically different techniques of real-
ne and quick-look display will be
quired.

In summary, Space Instrumentation
n be said to be a fertile field for the
plication of new ideas. These ideas
w encompass the most sophisticated
ncepts of solid-state physics, com-
unication theory, and astronautics.
t the most successful hardwares are,
d will continue to be, those that are
e simplest, most reliable, most ac-
rate, and available on short procure-
ent-lead times.

Liquid Engine Progress . . .

Power, Simplification, Reliability Still Criteria

Cheaper oxygen-jet fuels will be dominant for some time because of tremendous propellant consumption of rockets still under design

by Roy Healy

LOS ANGELES—Major current trends in the design and development of liquid propellant rocket engines for space vehicles and ballistic missile booster applications are (1) simplification for increased reliability, (2) higher thrust chamber pressures for improved performance, (3) optimized packaging for ease of installation and better accessibility and (4) clustering of individual engines to attain very high thrust levels.

The **Rocketdyne** Model H-1 engine, eight of which are to be assembled as the 1,500,000 pound thrust powerplant of the ARPA/Army *Saturn* space vehicle booster, exemplifies the current trends in large liquid propellant engines. Other new Rocketdyne engines under development, such as the 1,500,000 pound thrust single-chamber Model F-1, four of which will form the NASA *Nova* vehicle booster, will emphasize the same trends.

In mid-1958, Dr. Wernher von Braun, Director of Development Operations for Army Ballistic Missiles Agency asked Rocketdyne management to submit a proposal on clustering eight Advanced *Jupiter* engines for a huge space vehicle, then designated as the *Juno V*. He established design goals of simplification, improved performance, optimized packaging and clustering.

Available rocket engines were considered. Rocketdyne decided to propose a repackaged, uprated, much simplified version of the 150,000 pound IRBM engine being used in both the *Jupiter* and *Thor* ballistic missile program. We took advantage of the accumulated three years of developmental experience, including flight testing, on those programs as well as technical data from the *Navaho, Atlas* and *Redstone* engines. These enabled us to select and arrange components and the operational sequence.

• **Experimental testing**—Entirely separate from its production programs, Rocketdyne maintains an Experimental Engine group that constantly studies and tests new concepts and advanced designs for possible future use. A number of devices and techniques selected for incorporation into the H-1 engine had been proved promising by that group.

The Advanced Research Projects Agency accepted the Army Ballistic Missile Agency *Juno V* (now *Saturn)* proposal in September 1958. In that same month, Rocketdyne received the go-ahead to initiate engine design and development.

Rocketdyne adopted the philosophy of developing and delivering the H-1 as a single, basic, "any-position, plug-in" engine. This approach permitted the use of existing test facilities and

About the Author

Roy Healy is manager of the Saturn rocket engine program for Rocketdyne, a division of North American Aviation, Inc. Healy has more than a quarter of a century of experience in aircraft and rocketry. He first became interested in rockets in the mid-20's, and by 1935 had joined the ARS. He was president of ARS in 1942, and again in 1947.

His earlier work at Rocketdyne was on the Redstone system, and by 1954 he was supervisor of the unit. He participated in adapting the Redstone for use of Hydyne. In 1958 he was appointed as program manager for Jupiter engines.

testing H-1 engine . . .

INDIVIDUAL firing of Rocketdyne's H-1 engines for Project *Saturn* is accomplished in Santa Susana mountains.

reduced the propellant requirements for testing to a modest proportion. Utilization of basic components from the latest models of *Jupiter* and *Thor* engines allowed the use of existing tooling and manufacturing techniques and minimized the long-lead time for procurement of components. The approach is expected to make possible the goal of flight testing in late 1960.

The initial prototype engine was assembled to R&D type drawings. Firings were initiated at the Propulsion Field Laboratory in the Santa Susana mountains in December, 1958. The initial engine was delivered to ABMA after acceptance testing in April 1959, eight months after the design effort commenced.

• **Eliminated components**—To arrive at the H-1 engine, we modified existing *Jupiter* and *Thor* engines by eliminating many minor components, simplifying operation, and further improving and repackaging of major components. As an example of the former, the initial IRBM engines delivered in 1956 were built with five pneumatic pressure regulators and seventeen solenoid valves for proper start and shutdown operation. Gradual improvement of the engines reduced these requirements to a single pressure regulator and three solenoid valves. The more advanced H-1 design eliminates pressure regulators and solenoid valves entirely. A greatly simplified start sequence, using a pyrophoric fluid to ignite the main thrust chamber, has sharply reduced the electrical circuitry required. By mounting the turbopump assembly, valves, and other accessories directly on the sides of the thrust chamber, we achieved a lighter, more compact engine of smaller envelope dimensions.

Each of the eight engines powering the *Saturn* booster will be mounted into the missile by attaching the upper portion of the gimbal block assembly to structural members. The missile can then be controlled directionally by gimballing or swiveling the four outer engines. The missile guidance equipment exercises control through the medium of movable struts that adjust the positions of the outer engines.

The first cluster assembly and the firing of the eight-engine power-plant will be accomplished at ABMA on a mammoth test stand now being modified from its original *Jupiter* configuration. Initial launchings are planned from Cape Canaveral. Studies are in progress on parachute recovery of the *Saturn* first-stage booster.

The ARPA/ABMA *Saturn* booster is a natural outgrowth of Rocketdyne's experience in multi-engined projects. The original *Navaho* powerplant consisted of a pair of 120,000-pound thrust oxygen-alcohol engines. The advanced *Navaho* (G-38) consisted of three 135,000-pound thrust oxygen-jet fuel engines. Although the *Navaho* program was terminated prior to flight of the latter assembly, the engine development was progressing in a most satisfactory manner. In test firings, thrust levels of the clustered engines had reached more than 400,000 pounds, the highest level attained this side of the Iron Curtain at the time.

The original *Atlas* engine concept under development at Rocketdyne required a takeoff thrust of 660,000 pounds, a cluster arrangement consisting of four 135,000 pound booster engines, a sustainer of 120,000 pound output, and two 1000-pound thrust vernier engines for roll control and terminal velocity trim. During 1953, a breakthrough in thermonuclear warhead design permitted the sharp reduction in power requirements. This permitted the current *Atlas* concept of two boosters of 150,000 pounds each, plus a sustainer of 60,000 pounds thrust—with the vernier engine requirements remaining unchanged.

Extensive developmental and flight experience had been obtained on these cluster arrangements by the fall of 1958, when the Saturn program was initiated.

• **Parallel development**—The ARPA *Saturn* program, based on a cluster of existing engines, and the NASA program for development by Rocketdyne of a single engine of 1.5-million pounds thrust complement each other. When the more powerful NASA engine is available it too, in all probability, will be clustered to give the U.S. greater-tonnage-in-space capabilities. As more powerful engines are developed they will be used in groups of four, six, eight or more to make possible larger and larger spacecraft with increasing payload carrying capabilities.

One of the most effective factors utilized in the improvement of current production engines, and in the design of advanced models, has been Rocketdyne's extensive system of reporting troubles, inspection squawks and operational malfunctions. This embraces not only difficulties encountered in firing tests and missile launch operation, but also pre- and post-firing checkouts of the engine systems. The accumulated data are fed into automatic calculating and data storage machines, permitting rapid analysis and review of those items requiring design improvement. Constant scrutiny of reliability of the various components, operating sequences, etc., is invaluable in product improvement and the formulation of new engine concepts.

This continuous survey will sometimes reveal that the engine system has a component with an unacceptable record of malfunctions. In such a case

we review possible design and quality control improvements in that component. We also decide whether the component might not be eliminated and its function served by dual-function use of other components in the system.

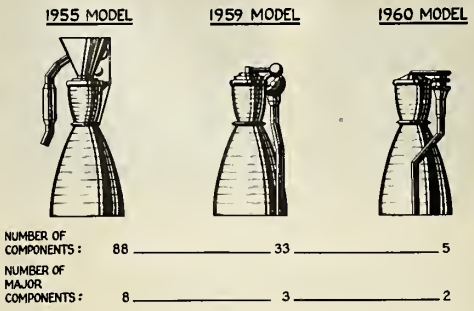
Rocketdyne conducted over 4000 large rocket engine tests during 1958 at the Santa Susana facility, using over 24 million gallons of liquid oxygen. In addition to the engine tests, close to 18,000 component tests were performed with propellants at the same facility.

The energy released in a 150,000-pound IRBM engine is equivalent to exploding some 1500 half-pound sticks of dynamite per second in the engine's thin-walled thrust chamber. To harness and control this tremendous energy, components and operational sequences must not only be reliable functionally but extremely precise in reproducibility of operation. It is not sufficient that a valve open or close upon receipt of a signal to do so—it must act in a predetermined number of milliseconds and in proper time relationship (again in milliseconds) to the operation of other system components. It is because of this rigid requirement that components developed for industrial use, and even the more rigorous requirements of aircraft use, are not suitable for rocket engine application.

• **Severe specifications**—In addition to the criticalness of operation as outlined above, the extreme temperature and vibration environments of rocket operation make more severe the specifications for rocket engine parts. The fact that America's missile program is progressing in a satisfactory manner is a tribute to the ingenuity and capabilities of this country's rocket designers.

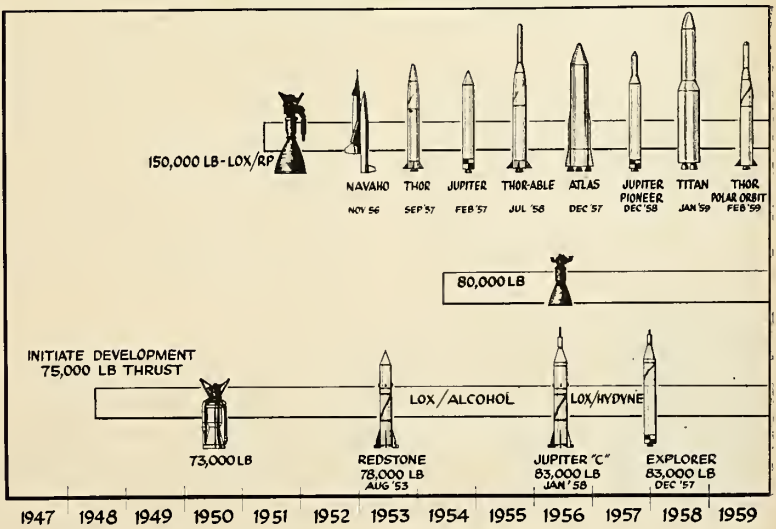
Some clearly defined trends are becoming apparent in the liquid propellant field. For future ballistic missiles the desirability for instant readiness has promoted interest in the storable propellant combinations. Because of good performance and non-corrosive nature, nitrogen tetroxide is tending to replace the red and white fuming nitric acids as an oxidizer. To maintain performance at the oxygen-jet fuel levels, unsymmetrical dimethylhydrazine and hydrazine are the most commonly used fuels, both being hypergolic with the nitrogen tetroxide.

All of Rocketdyne's current production engines, designed for operation with oxygen-jet fuel, have been fired with storable propellants after relatively minor modifications. A number of our experimental engines have also been operated with the storable combinations.



Increasingly more powerful space vehicle booster rockets are inevitable. Power levels in the tens of millions of pounds of thrust are now being considered. The tremendous propellant consumptions of these powerplants, and the fact that instant readiness is not a requirement, make it probable that the plentiful, inexpensive (2¢ a pound) and easily handled oxygen-jet fuel combination will be dominant for some time to come. Sea-level specific impulse values in the 245-275 second range can be expected from these booster engines.

For first-stage engines the trend toward higher chamber pressures continues with newer designs featuring thrust chambers operating in the 1000 psia range. Conversely, for upper-stage and in-space engines the trend is toward thrust chambers operating in the 200 to 300 psia range, and there are advocates of much lower pressures. These lower pressures, coupled with recent advances in the fabrication of lightweight, high-strength pressure vessels, makes attractive simple, pressure-fed rocket systems using helium as the pressurant. In such simple systems the tanks, lines and thrust chamber can be integrated into a compact power package.



The increased importance of specific impulse, and the relatively small size of upper stages as compared to the huge booster stage, makes the high energy propellant combinations, such as fluorine-hydrazine and oxygen-hydrogen, attractive for upper stage use. Vacuum specific impulses in the 350- to 475-second ranges may be attained.

The advances achieved in the past decade by the high-thrust liquid propellant rocket engine have been outstanding. Continuation of current trends in seeking ever more powerful, more simplified, higher performance engines will make the accomplishments of the next decade even more fantastic. That time-span may see the fulfillment of a goal that I knew 25 years ago only as an amateur rocketeer's dream—the landing of a man on the moon.

SIMPLIFICATION and reliability have been major efforts in liquid propellants.

Large Rocket Engine Development

SERIES OF PHOTOGRAPHS of dog-carrying *Sputnik II* made it possible to deduct that the total length of rocket body and

Astrometry Progress . . .

Little Support for Vital Program

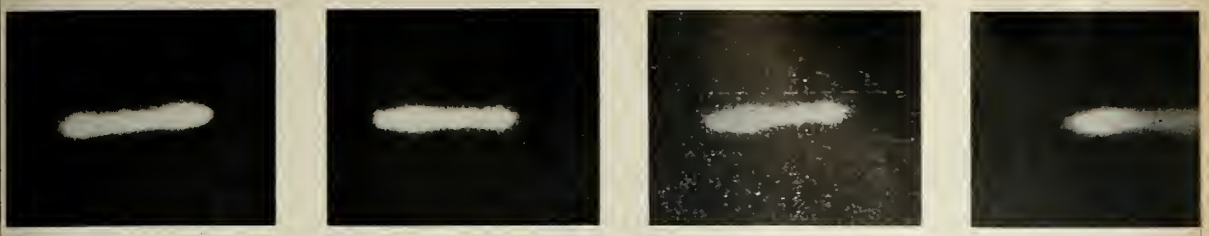
Additional equipment and new methods for using it are needed if U.S. is to have continuous location capability for spacecraft

by Dr. Douglas Duke

MELBOURNE, FLA.—For defense reasons, it is mandatory that the U.S. be continuously aware of the space location of all earth satellites and space vehicles. This is so, due to the possible future necessity of distinguishing approaching ballistic missiles from other vehicles which present no threat. There exist, in addition, other reasons that make this capability very desirable. Principal among these are performance analysis of our own space vehicles, geophysical and geodetic applications, testing of instrumentation capabilities and obtaining further information on the structural and operating features of foreign satellites.

A beginning toward developing space-location ability was made, shortly after the first *Sputnik* made its appearance, with the establishment of Project *Spacetrack* within A. R. D. C. The purpose of this project was to gather the maximum possible amount of tracking and configuration data on foreign satellites. The writer had the good fortune to be intimately involved with these efforts at the Atlantic Missile Range for the first 15 months of the project's existence, during which time the A. M. R. furnished the majority of the information received by the *Spacetrack* Filter Center at A. F. Cambridge Research Center, where prediction computations were carried out. During this period, there were many successes and failures. These have indicated the direction in which the development of new instrumentation systems and data-reduction techniques should move and also the most efficient organization of existing facilities.

One obvious method of knowing the position of a space vehicle at any arbitrary moment is simply by maintaining continuous track of it. However, this would require world-wide instrumentation, which would be extremely costly, especially in the case of satellites that revolve only a few hundred miles above the earth's surface. Since it is reasonably expected that there will be a considerable number of orbiting satellites in the space about the earth in the near future, there would be an increasing requirement for simultaneous tracking of more than one body at individual stations. This would further increase the scope and cost of a continuous real-time tracking operation on all space vehicles.



Such an operation is, however, quite unnecessary. The laws of celestial mechanics show that the relative orbit of one mass point about another will be an ellipse. In the absence of any external perturbing influences the geometrical features of the ellipse will remain forever the same, as will the period of revolution about the orbit. Once we determine these quantities accurately, we can use them in a machine computer to predict where the object would be considerably later in the future. We could also improve the accuracy of the quantities continuously, merely by obtaining occasional later observations and combining these with those obtained earlier. Thus the need for real-time tracking could be reduced drastically and the capacity of a space surveillance system would be very large.

Unfortunately there do exist disturbing influences which impair the above prediction method considerably. The fact that the earth is not a perfect sphere, but flattened and otherwise deformed at the poles, and the presence of a tenuous but definitely existing trace of the atmosphere out to several hundred miles—both cause large departures from the invariant elliptical orbit, especially for close satellites. The earth's

About the Author

Dr. Douglas Duke is technical adviser for space technology at Radiation Inc., Melbourne, Fla. From November, 1957, to January, 1959, he was project engineer for the Spacetrack Project at the Atlantic Missile Range. Duke obtained his Ph. D. in astronomy and astrophysics from the Yerkes Observatory at the University of Chicago in 1950. He taught astronomy at several universities and has worked in the fields of missile and satellite tracking instrumentation since 1955.

unseparated instrument compartment was slightly less than 80 feet.

oblateness affects the space orientation of the orbit but not its size, shape, or period of revolution. The drag caused by the thin layers of the atmosphere has just the converse effect, not affecting the former ones, but causing changes in the latter quantities. For vehicles quite far from the earth, the above effects become small, but in this case, we must then consider the perturbing gravitational effects of the moon and the sun.

• **Complex calculations**—Practically all of the early work done at A. M. R. involved close satellites, so that earth's oblateness and atmosphere drag were of great importantce. The oblateness provided only minor difficulties since there existed theoretical formulas and enough observational material to take these effects into account reasonably accurately. The difficulties encountered with atmospheric drag have, however, been quite severe. Although the loss of energy due to drag is small during a single revolution, the effect is a cumulative one. During each revolution, the size of the orbit is reduced slightly by drag. Therefore, on the next revolution, the satellite spends more of its time in the lower atmospheric region where drag occurs, and the drag itself is greater than on the previous orbit. The net result is a decay type of behavior of the period of revolution and the size of the orbit. Both values decrease at an ever-increasing rate, until the satellite passes so low into the atmosphere that the remaining orbital energy is completely dissipated by a final meteor-like plunge to earth.

Supposedly a knowledge of the atmospheric density as a function of altitude and of the drag coefficient of the satellite should allow fairly accurate calculation of the future course of the decay of the orbit. But our knowledge of atmospheric densities at high altitudes is quite meager. We also have little idea how the densities may vary as the hour of the day, the season of the year, or the latitude are changed. Moreover, in the case of foreign satellites, our knowledge of configuration details is scant so that the drag coefficient is not well known. Since these bodies also have had considerable tumbling motion, the effective cross-sectional area of the drag-producing surface has been subject to unpredictable changes.

• *Sputnik* **deviations**—The result of all this is that position predictions of low altitude foreign satellites have been far from satisfactory. The drag rate has varied in essentially an unpredictable manner. An example is shown in Fig. 1, where the rate of change of the period of revolution is graphed with revolution number since launch for the last-stage rocket of *Sputnik III (1958 Delta 1)*. The oscillations present seem small, but over several hundred revolutions, they produced errors of the order of twenty minutes in the time of appearance of the rocket. For this reason, the distant past history of orbit behavior was of little value in making predictions. At the *Spacetrack* Filter Center, it was necessary to restrict the computer analysis to perhaps the last one or two weeks of observational data, predict future positions for perhaps ten days, and then hope for the best. Usually departures of several minutes appeared in three or four days, and often it was necessary to repeat the prediction calculations several times a week. Otherwise the calculated passage times would soon have been in error by a considerable fraction of an hour.

Even the position in the sky is affected seriously by errors in the time of appearance. At the latitude of the U.S., the earth rotates about 15 miles every minute. An error in appearance time of ten minutes means that the satellite will pass over a point 150 miles distant from the calculated point. At low passes (height 150 or 200 miles), this means either a large departure in the place in the sky where it will be seen, or that it will pass too low on the horizon to be seen at all.

It is evident that the neat theoretical scheme, which called only for "occasional" observations to verify the calculations, was completely imposible. In the case of the *Sputniks,* there were two periods every six weeks, each approximately one week in duration, during which they could he tracked optically from the Atlantic Missile Range. At other times, the objects passed overhead either during broad daylight or in the middle part of the night, when the earth's shadow allowed no optical target from reflection of sunlight.

• **Triangulating** *Sputniks*—The tests involved principally the use of Askania cine-theodolites and Mark 51 optical trackers. Every attempt was made to obtain angular positions from at least two stations on the range, so that the actual space position could be triangulated. Since there is a fair amount of cloudy weather along the range, this meant usually four observing stations per pass to have a high probability of at least two successful sets of angles. The Askanias provided an accuracy that was an order of magnitude better than the optical trackers (.01 degree vs. 0.1 degree), but since all the Askanias at A. M. R. are in a small area around Cape Canaveral, it was necessary to use the optical trackers whenever downrange data was desired. It is expected that theodolite coverage soon will be available downrange.

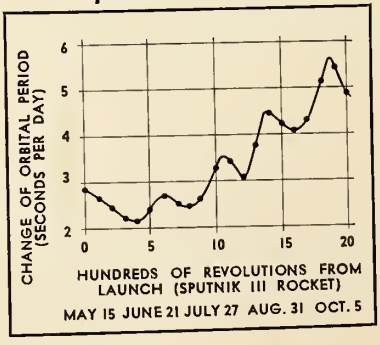
The highest accuracies obtainable optically are those of the ballistic camera. But such high accuracy is only needed for geodetic studies with satellites. For merely keeping track of the period of revolution, the ability of the Askania to track fainter objects and the greater speed and ease of theodolite data readout made its use most practical. Of course, there is a delay for processing and reading the film. This delay could be eliminated by digital readout equipment. It is expected that such equipment will shortly be procured for A. M. R. theodolites. When this is so, real-time satellite angle position can he fed directly to the *Spacetrack* calculation center at Cambridge for instantaneous checking and correction of calculated satellite position.

Even after these improvements have heen made, there still will remain some difficulties. One is that of observing faint satellites. In the case of the *Sputnik* rockets, their relative brilliance eliminated such a problem. But with the smaller American *Explorer* and *Vanguard* satellites, and for the *Sputnik III* nose cone, considerable observation difficulty has been encountered. These objects are usually just barely visible or entirely invisihle to the unaided eye. Therefore, the theodolite observer cannot take advantage of the wide field of view of the unaided eye but must point his tracking telescope in the predicted position and wait for the satellite to

enter the field of view. This field is only about four degrees in diameter. Usually, the object either does not enter the field, or passes near the edge so quickly that observation is impossible. This difficulty is greatly enhanced in the case of non-spherical objects that are tumbling. The intensity of their light varies widely. Thus the object may be much fainter than maximum light during the short time it is in the field of view.

• **Telescopes needed**—The addition of very wide field, low-power, high-brightness acquisition telescopes is a prime necessity, if full success with theodolites is to be realized. The field of view should be about 20 degrees in diameter. Thus the area of the sky in the field of view will be 25 times the present case, and the probability of acquisition correspondingly larger.

There are other places where significant improvement is possible, subject to development of suitable equipment. Image-tube or television techniques should make it possible to detect the brighter objects in broad daylight. This would mean possibility of optical track at least once each clear day and give much greater continuity to the data. There would be no 4-week "holes" when daytime track was impossible. Also, a method of determining the tracking errors of the theodolite operators in real-time would improve the accuracy. Corrections for these errors could be applied automatically to the digital readout of theodolite axis angles. Without such a tracking correction, one is dependent on the pointing ability of the operator. Although performance appears to have been excellent in the past, such correction capability seems quite desirable.



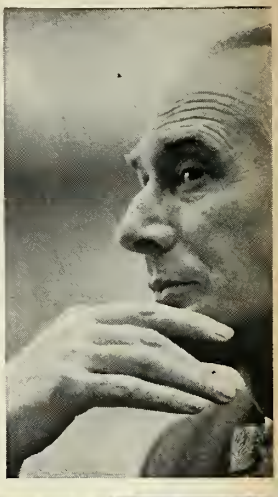
Radar tracking of satellites at A. M. R. has been extremely limited. This is completely due to lack of electronic acquisition equipment to furnish pointing angles for the precision radars. Without pointing information, it has proven to be useless to attempt to pick up satellites with very narrow-beam high-gain systems. Successful track has only been obtained when the target was optically visible so that optical trackers could be used to direct the radar antennas. Results of these cases indicate clearly that addition of electronic acquisition equipment would increase coverage tremendously.

Continuous radio interferometric data has been obtained on the nose cone of *Sputnik III (1958 Delta II)* since its launch on May 15, 1958. A 20 megacycle North-South oriented baseline has made it possible to determine latitude crossing times each day. This unbroken series of observations has yielded interesting information on perturbations of the period of revolution. Considerable efforts have been made to increase the sensitivity of the system, and several other improvements are planned.

• **80-foot rocket**—One of the most interesting results obtained at A. M. R. is the configuration photographs of the *Sputnik* rockets. We were fortunate in possessing a good amount of high-performance long-focal-length tracking optics, due to long-range missile tracking requirements. With such equipment, it was possible to obtain recognizable images to distances of three or four hundred miles. A series of photographs made of the dog-carrying *Sputnik II* on Dec. 21, 1957, at a slant range of about 190 statute miles is shown on the preceding pages. From such photographs, it was possible to deduce that the total length of the rocket body and unseparated instrument compartment was slightly less than 80 feet. At the time this length measurement met with considerable disbelief. However, the reduction method was exceedingly simple and left no possibility for gross errors. That the injection of such a configuration into satellite orbit was possible was demonstrated last December when the U.S. orbited an entire *Atlas* missile.

Gradations in brightness along the length are apparent, and occasional frames show "hot spots" due to specular reflection of the sun's light from certain surface areas. Tumbling of the object is quite evident. However, details other than the gross length of the object are too blurred for identification. It is reasonably certain that this is not due to tracking error, since, on the best film records, the positions of successive images with respect to the frame edges are nearly constant. It is likely that the limitation is related to atmospheric turbulence.

Sputnik III Record



The difficulties that had to be overcome to obtain these images can only be appreciated by the people at A. M. R. who were involved in the effort. Acquisition by tracking personnel was hampered greatly by the presence of a dome with only an opening for the telescope. The absence of wide-field finder telescopes, such as those discussed above on theodolites, and the lack of any external optical tracker located in the open, which could provide coarse pointing information, greatly reduced the amount of coverage. All the telescopes have conventional two-axis azimuth and elevation mountings. This meant that on high elevation angle passes the satellite could not be tracked as it passed nearly overhead at the very times when the slant range and optical path through the atmosphere were at a minimum.

• **Missile tracking easier**—Of course the instrumentation described above was never intended to be used for satellite tracking, but rather for the launching of missiles from Cape Canaveral. The problems described above are a consequence of this. Compared with satellite observation, the acquisition of a gradually accelerating missile perhaps 20 miles away is a relatively simple matter. Indeed none of the equipment used at A. M. R. for tracking satellites was designed for that purpose. Changes in the equipment, methods of using equipment and the organizational effort will all have to be effected if optimal gathering of information is to take place. Personnel involved in the *Spacetrack* program and other tracking programs have acquired much practical experience and capability. Yet the efforts made up to now have, speaking generally, been too small. They have been made for the most part by individuals or small groups of individuals working almost alone. Relatively little interest and support has been evident up to the near present. We must accelerate the effort if the mission of continuous location capability for all satellites is to be attained within a reasonable time. A high level of cooperation between responsible agencies and between experienced technical and administrative personnel is mandatory. It is hoped that recent plans for an overall study of this problem will lead to its successful solution.

The author wishes to express his gratitude to Walter H. Manning, Jr., Spacetrack task scientist at the Atlantic Missile Range, who assisted in the preparation of the article and the accompanying photographs.

WASP

THESE MEN DO ALMOST NOTHING BUT THINK

Unique new group helps Westinghouse anticipate and plan for future military needs

It's harder than ever to stay out front in defense. Weapons systems are now fantastically complex. New innovations—like thermoelectricity and molecular electronics—threaten to make key subsystems obsolete overnight. New developments may suddenly reduce the tactical usefulness of a U. S. weapons system.

Westinghouse, like many other firms, has been concerned about how to meet this problem—and how to organize its many R&D and manufacturing operations to more effectively support America's increasingly complex defense needs. It seemed that the organization which had worked fine in the past simply wasn't adequate for anticipated future demands.

So things were completely reorganized in February, 1958. A new Defense Products Group was established, centralizing control of all defense-oriented activities within the company.

But a most interesting—and promising—part of this new organization, the new Westinghouse Advanced Systems Planning Group (now commonly called WASP), wasn't announced publicly until August.

This was a significant development. Since technology is moving faster than ever before, there's a real need to effectively anticipate what will be needed in 5 or 10 years. If this can be done, longer-lived defense systems can be developed more quickly and substantial sums can be saved. WASP should be able to provide the advance thinking needed by Westinghouse to meet this need.

Staffed with hand-picked engineers and scientists—specialists in electronics, outer space, atomic power, ASW, operations research, etc.—and headed by Allan Chilton (top center photo above), WASP operates on a unique charter: to concern itself primarily with

YOU CAN BE SURE... IF IT'S Westinghouse

CAN A SYNCHRO MAINTAIN ACCURACY

OVER A WIDE RANGE OF TEMPERATURE?

Synchros have to take punishment. They are often exposed to blistering heat and stratospheric cold . . . and they still must operate accurately.

Naturally, Ketay synchros meet *and surpass* the new MIL-S-20708A ambient temperature requirement of −55° to 85° C. (or to 75° C. for size 23). Even more important, they give you a remarkable 6 minute accuracy *over this whole temperature range.*

Ketay is the *only source* currently manufacturing and shipping a complete line of the new Mil-type synchros. They are available in production quantities in sizes from 8 to 23, with 60 cps units as small as size 15. Because of their superior accuracy, with some units offering 3′ accuracy at room temperature, Ketay synchros one or more sizes smaller than previously required may often be used.

Ketay engineers are working on many advanced environmental and accuracy problems in developing prototype systems, and have an unusual degree of experience in high temperature work. Why not call or write for help in solving your special problems?

Control, Guidance and Navigation Progress . . .

Propulsion Available Will Set Designs

Biggest problem areas are in components hardware and in this area inventiveness and imagination will make greatest inroads

by S. S. Edwards, W. C. Griffith, & J. I. Osborne

Speed is, of course, the key to space flight. The fact that the possibilities of space flight are presently being discussed arises from the recent development of large rocket motors capable of accelerating sizeable masses to speeds approaching escape velocities. Speed is required to overcome the inexorable pull of gravitational fields and to negotiate the tremendous distances involved in a feasible time. Command of thrusting power, therefore, makes possible the contemplation of space travel. However, the present state of propulsion technology does not allow unlimited power. It seems quite reasonable to assume that consideration of power available will impose difficult design requirements on space vehicle weight as also on design of guidance and navigation systems.

In principle, Newton's laws of motion and universal gravitation provide a basis for complete solution of space flight problems in the sense that initial conditions at launch may be adjusted to arrive at any desired place at the correct time without the necessity of providing navigation and terminal guidance systems. However, it is at present inconceivable that a space vehicle could be accelerated in a few minutes to the magnitude and orientation of its velocity vector with sufficient precision for a trip to be measured in weeks or months. Such a direct extrapolation of present technology is obviated by uncertainties in the original velocity and acceleration vectors and in the physical constants.

The gravitational constant is known from laboratory measurements with sufficient accuracy to yield satisfactory figures for the masses of all bodies having observable satellites. In the case of the Moon, Venus, and Mercury, however, the masses have been determined only indirectly and with considerably less accuracy. This does not create any real difficulty, for better data will certainly become available from exploratory probes before actual landings are attempted. The 0.02 percent uncertainty in the astronomical unit, on the other hand, presents a significant problem. Thus, the range of Venus at closest approach is unknown to about 5000 miles, a sizable figure in terms of navigational requirements. Further work with radar returns from the planets, however, will certainly help science to resolve this question.

• **Trajectory uncertainties**—By far the largest present uncertainties originate during missile launch and early powered flight. These result from misalignment in guidance reference; time of launch, thrust direction and magnitude variations; and atmospheric winds. Improved technology may be expected to reduce all of these contributions somewhat but cannot be expected to eliminate them entirely. Thus wide course and terminal navigation and guidance systems will be necessary.

We must assume that by the time a spacecraft reaches a point where its motion is dominated by the gravitational attraction of the target body, the vehicle is on a hyperbola that does not intersect the surface of the target. In general, the energy required to shift trajectories is smaller the farther away the vehicle is from the target. The desirability of making changes as early as possible must be weighed against the penalty of carrying sufficiently precise navigation and guidance equipment to determine what the required changes actually are.

For an initial heading error, simple geometrical analysis indicates that the fuel required to correct the heading

ABOUT THE AUTHORS

Edwards

Griffith

Osborne

S. S. Edwards, W. C. Griffith and J. I. Osborne are with the Missiles and Space Division of Lockheed Aircraft Corp. at Palo Alto, Calif. Edwards, assistant manager for aerodynamics and flight sciences in spacecraft and missiles research, has been with Lockheed since 1956. He was with the Ames Aeronautical Laboratory of NACA at Moffet Field, Calif., from 1947 to 1956. Griffith, associate director for spacecraft and missiles research, was a professor of physics at Princeton University from 1950 to 1957, when he joined Lockheed. Osborne, assistant manager for missile dynamics and performance, was engaged in research at the University of Southern California, Douglas Aircraft Corp. and Boeing Airplane Co. before joining Lockheed in 1956.

favors mid-course equipment . . .

halfway to the destination would be three times that required at one-quarter of the way to the destination. If the correction were made at the three-quarter range point, the fuel used would be as much as at nine times one-quarter of the way. Therefore, the trade-off between fuel weight to correct heading and additional weight for precise navigational equipment to determine heading would appear to favor the mid-course navigational equipment. The above computation assumes that the velocity along the course and the fuel weight required to correct a given angle is constant. Fuel weight of approximately 1.4% of vehicle weight is required to correct an error of 1 milliradian for specific impulse of 240 seconds. Improvements in specific impulse will, of course, improve this number.

If the launch guidance requirements are relaxed because of the availability of excess power, a mid-course navigation system is required. Path correction by power application requires that vehicle orientation with respect to its velocity vector is known. The inertial reference system used during the launch maneuvers probably could not be depended upon to maintain orientation to the order of accuracy required for mid-course maneuvers, at least without resetting. However, electronic gyros, presently under development, might perform this function.

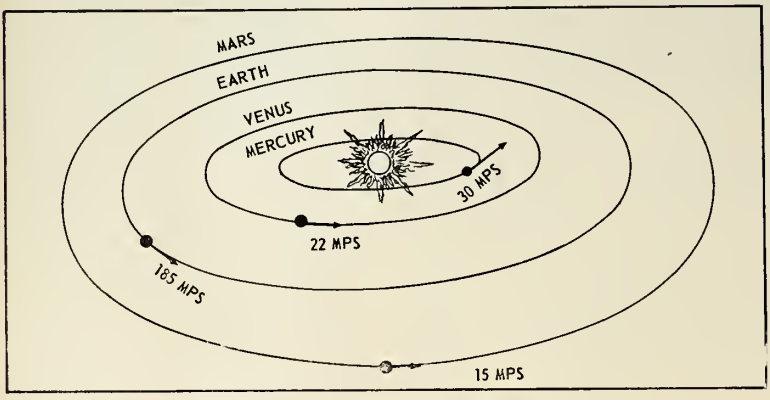

FIG. 1—Solar System Configuration.

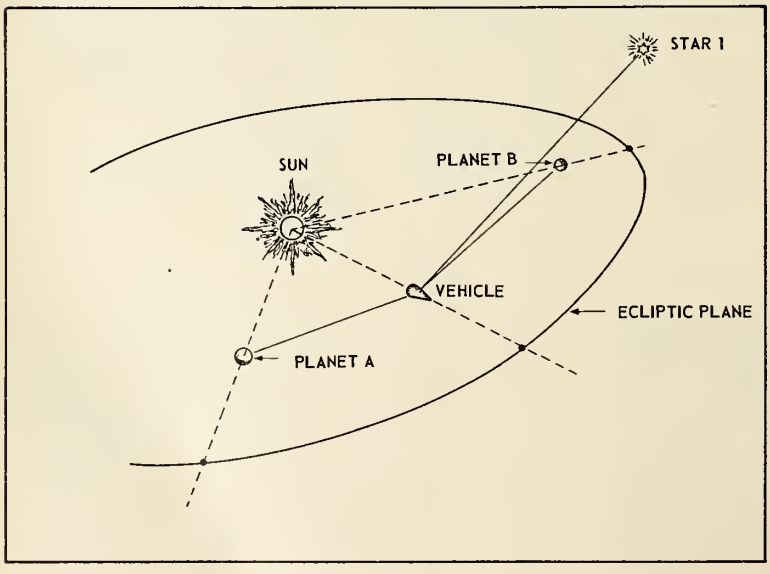

FIG. 2—Position Determination.

• **Celestial astrogation**—Star position readings taken with a sextant may be used to correct a gyro, which can then be used for continuous reference. The accuracy of celestial observation is greatly enhanced if the missile axis system is stabilized in space. This would rule out the use of spin stabilization. Also, changes in vehicle orientation are awkward in a spin-stabilized system. Accordingly, it makes better design sense to spin small gyro elements in an inertially stabilized reference system and measure and control vehicle attitude with respect to these axes. Maintaining constant attitude control by referencing spinning gyros has the disadvantage of cumulative expenditure of power.

Another method might be to omit the gyros and use the stars as a reference system. The vehicle would then be stabilized with reference to the stars probably only during the interval required to fix position.

We assume that the flight is in the ecliptic plane and that the configuration of the solar system is known at all times (Fig. 1). Position in the solar system may be determined in a number of ways, each of which offers certain advantages of accuracy or convenience. The direction of the sun offers the most obvious line for vehicle reference (Fig. 2) and two planets (one of them the target) or a star and planet along with a clock completes the required information. The alternative use of radar ranging on the target has the advantage of giving better range and velocity data but suffers from the extra payload for power and antenna, and gives less angular resolution.

Velocity is obtained by successive position readings and the time interval between them. In the process of evaluating these data, it should be remembered that the inertial guidance used during the launch phase has a digital computer as a major component. The position and velocity measurements discussed are then inputs to the digital computer for orbit computation and error determination. Knowing the orbit errors and the vehicle orientation, it is possible to make mid-course corrections to the trajectory.

Problem areas exist in the realization of the component hardware designed to perform as a system. Here is where inventiveness and imagination will make the greatest inroads in the future.

• **Landing problems**—Having successfully traversed the vast distances separating the earth and planet destination, the successful space flight yet must negotiate the tricky maneuver that

...NEWS IS HAPPENING AT NORTHROP

Now being produced and delivered to the U.S. Army Signal Corps, the Radioplane SD-1 gives greater battlefield surveillance flexibility to combat units than ever before. (This photo of terrain was actually taken from an SD-1 at 1,000 feet.)

RADIOPLANE PRODUCES FIRST COMBAT-READY SURVEILLANCE DRONE

Meeting tough Army Signal Corps requirements and being produced in operational quantities, the SD-1 is proved and ready to fly unmanned photo reconnaissance missions for tactical troops.

Highly mobile, the camera-carrying SD-1 may be zero-length launched in rough terrain from a camouflaged position. It is flown by remote control over enemy installations on surveillance missions without risking a pilot's life or man-carrying aircraft. Within minutes after the SD-1 returns from its mission, photographs are delivered to the requesting unit.

Other specialized sensory equipment may be carried by the SD-1 depending on particular mission requirements.

This Army-Radioplane achievement exemplifies Radioplane teamwork with all of the U.S. Armed Forces. Radioplane provides a complete drone family spanning medium speeds through supersonic performances.

will allow descent to the surface. Presuming that the incremental velocity given the vehicle in powered maneuvers has not exceeded appreciably the escape velocity from the earth, the speed at which the trajectory has been traversed is approximately the orbital velocity of the earth or about 18.5 miles per second. If the terminal phase of the flight were to result in a tail chase maneuver, the only planets which could be overtaken would be those located at a greater distance from the sun than the earth, in which case, the vehicle would have excess velocity over that of the planet (Fig. 2). Another possibility is that the vehicle could be guided into a relationship such that it could be overtaken by the planet (which then has the greater speed advantage). There are certain advantages in considering such maneuvers in that presumably very little reference to the vehicle-objective relationship would be required. This could result in advantages particularly if rapid computational methods are not available. The interception in which approach is made at large angles between the vehicle and target orbits involves an increasingly more precise monitoring and correction of the closing condition.

To negotiate a landing upon the surface of the planet, the relative differences in the kinetic energy per unit mass between vehicle and target must be considered. Eventually, of course, soft landings will be made in which this difference is adjusted essentially to zero either through atmospheric braking or controlled impulse. Several maneuvers that could be considered are:

1. Ballistic descent with powered braking.
2. Capture in the gravitational field of the target planet and ballistic descent from satellite orbit.
3. Lifting entry from orbit about the planet.

The band of approach paths (figure 3) for which impact can occur is, of course, larger than the band of paths for which appreciable curvature of the hyperbolic paths in the vicinity of the target occurs. Accordingly, guidance accuracy for the collision course is less severe. The large entry angles, however, would essentially preclude the possibility of using atmospheric deceleration to expand excess energy. Reliance upon powered landing would be required.

To orbit about the target planet in preparation for a deorbiting maneuver requires that the approaching vehicle be guided into a fairly narrow circumferential band at which point the vehicle velocity relative to the planet must be adjusted downward to appropriate orbital speeds. Unless atmospheric braking is obtained this deceleration must be accomplished in a powered maneuver. To graze the atmosphere—a very thin band relative to the planet diameter—requires the greatest precision in the guidance and control.

The problem of landing on an airless planet places greater requirements on the flight control system (and of course a rocket fuel supply) than those of going into orbit or landing in an atmosphere. Terminal guidance requirements, however, are somewhat less severe. Here the initial objective is to move into a trajectory which has zero angular momentum with respect to the intended landing point. This presents a relatively simple computational problem since Mercury and all the airless moons of the solar system for which observations are possible have a rotational period equal to their orbital period, i.e., they present the same face to the parent body. Thus, the landing point is under continuous observation for a long time.

• **Fuel-saving trick**—Corrections to the hyperbola of approach should be made as early as possible to conserve fuel, just as in the other cases being considered for the same reason. Deceleration to land using retro-rockets should be postponed as long as possible compatible with the maximum tolerable "g" limit. Probably the most satisfactory terminal navigational aid is a radar that makes use of pulses for ranging and Doppler shift for velocity of approach. With this information the retro-rocket thrust can be programmed for proper descent.

Special problems arise in the last few hundred feet. Accurate measurements of height become difficult because the time interval between pulse and return is very short (on the order of one microsecond). The large ion cloud from the rocket exhaust would certainly render any microwave velocity measurement useless by masking the small doppler shift existing. No automatic control system appears to have been devised that improves on the possibility of human observation and control of the actual landing. This is probably very desirable, anyway, since selection of the exact landing spot to avoid rock or crevasses can be done by a human pilot. The control system should be designed to handle like that of a VTOL aircraft, for which adequate training and experience is readily available.

Significantly, the problem of landing upon the surface from an orbit about a planet is nearly in the dress rehearsal stage at this time in Project *Mercury*. Certainly the important major framework associated with this problem is fairly well understood essentially as a legacy of the ballistic missile program. Challenging problems exist in all areas; however, the encouraging and exciting fact remains that no insurmountable factors exist to prevent man's exploration of space.

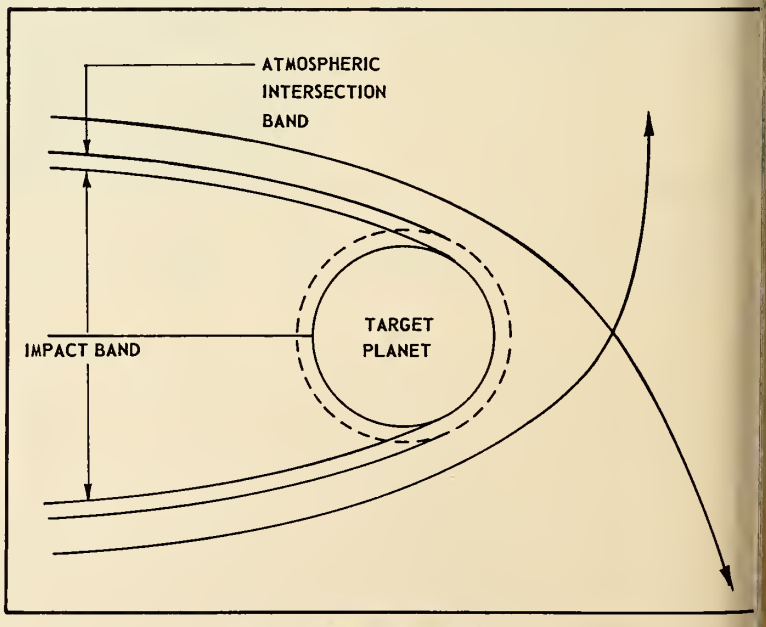

FIG. 3—Hyperbolic Approach Orbits.

ENGINEERS ☆ SCIENTISTS

Are you getting these advantages in your present position?

☐ **Space-age assignments.**

Boeing's space-age orientation, its advanced research and test facilities, and its wide weapon systems management experience have already laid the foundation for continuing growth and leadership in the future. Underway are company projects probing the very frontiers of knowledge—including orbital, lunar and interplanetary systems.

☐ **Advanced research facilities.**

Boeing's research, development and engineering facilities are among the most varied, extensive and complete in the industry. If your field is design, you'll get the answers you want, in a hurry. If you're in research or development, you'll be working with equipment as modern as this minute. Backed by extensive research laboratories covering a tremendous range of engineering fields and the sciences, you'll make more progress—faster. And you'll work with men who have literally "written the book" on the state-of-the-art.

☐ **Opportunity for advancement.**

Boeing takes steps to see that you don't get lost in the shuffle. You work with small, integrated teams where initiative and ability get plenty of visibility. A personal merit review every six months assures you a continuing opportunity for individual recognition and advancement. In addition, you are eligible for advancement to higher level positions at any time. Since its very beginning, Boeing has recognized the desirability of developing personnel for added responsibilities.

BOEING

Seattle • Wichita • Cape Canaveral

☐ **Better family living.**

There's a real bonus of better living in the heart of the evergreen Puget Sound area. Dramatic sea-and-mountain scenery and year-round outdoor recreation are unsurpassed. Your surroundings are air-conditioned by nature—four full seasons, yet moderate, comfortable. Average minimum temperature is 46.3°. Sea-level and ski-level are only an hour apart. Per capita ownership of sail and power boats is America's highest. You play your best, and work your best—because both career and living conditions are ideal.

There is more to getting ahead in engineering and science than one's own ability. Of almost equal importance is the environment in which you work. If, in your mind, there is any lingering doubt that your present surroundings do not meet all *the requirements for achieving your fullest professional growth, it will pay you to check the advantages Boeing can offer.*

Falling Behind Engineering Advances

by Dr. T. C. Helvey*

ORLANDO—The limitations of the human organisms are probably the most restrictive in astronautics. Engineering has solved the problems of boosting a projectile into orbit about the earth and of escape from the earth's gravity. If it were desired, the engineers probably would be able to shoot a small object out of the solar system—perhaps even from the galaxy. But a whole host of separate questions must be answered—indeed several new sciences must be developed—before men can travel safely any great distance in space.

Nevertheless, we can predict that our species will solve these problems if they can be solved. Man is a proud creature. His ambition knows no limit.

One of the limitations the human organism probably will impose for the next few centuries is in travel radius. Since medical science is unlikely to prolong the average human life beyond 120 years and it is hardly likely that the speed of light will be exceeded, the presumed maximum length of a manned trip is 100 light years. This would set an action radius of 50 light years if we plan a return to earth.

But our own galaxy, the Milky Way, has a diameter of 200,000 to 300,000 light years. The 50-light year radius would restrict travel to a tiny segment of the galaxy.

To extend this action radius, there are two approaches that do not require artificial tampering with the human organism. One is to slow the normal body functions to retard aging. Scientists in the fields of biophysics and biochemistry are studying suspended animation. Although this would involve loss of consciousness for very long times, amazingly little psychological aversion has been aroused by discussion of this method. The other approach is based on the dilatation of time implied by Einstein's theory of relativity. The theory states that time slows down for all objects traveling at speeds approaching that of light. In this case, consciousness would not be lost, but the extremely low perception rate would sharply reduce the effectiveness of human observations en route.

* *Research Division, Radiation, Inc., Orlando, Fla.*

HUMAN capability of performing a certain psychomotor function while under acceleration. (Fig. 1)

• **Genetic attack**—A more radical attack on the problem is that of genetics. Perhaps we can adapt man to greater endurance of the stresses inherent in space. Of course, the utilization of presently known principles of eugenics to breed astronauts would be time consuming. Such projects would last many centuries. But it is conceivable that controlled artificial mutation, brought about by some mutagenic agent or radiation, might speed the process. However, we must face the fact that there are deep philosophical implications to the thought of creating a *homo sapiens var. spatialis*. They must be realized as such.

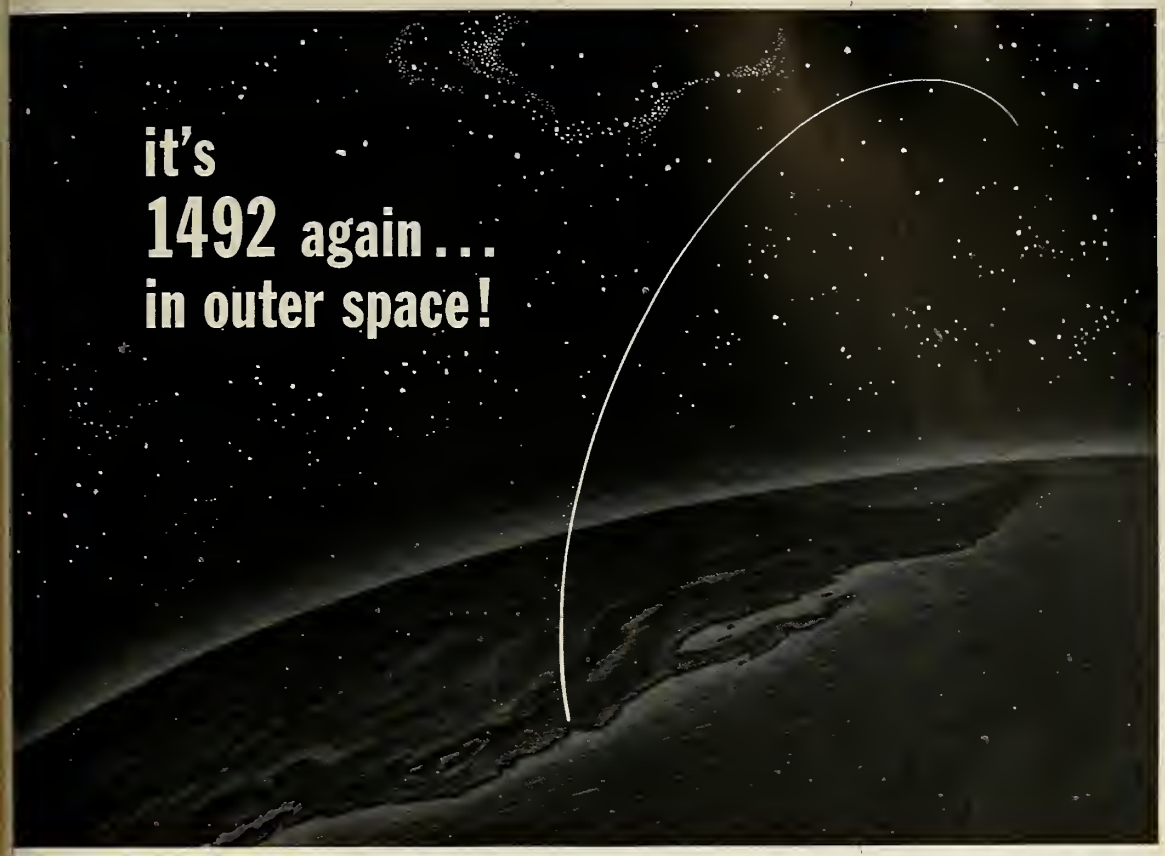
In the closer future, we shall have to adapt the space machine as much as possible to the human limitations. By using symptomatica and possibly post-hypnotic suggestion we may make the astronaut more resistant to space stress.

What is the problem of space medicine in the immediate present? The primary task is to maintain the normal operational integrity of the human organism under space-equivalent conditions. We must consider human reactions in terms of performance, stress endurance, bodily changes and behavior.

Several overlapping sciences can serve us in controlling these factors. The fields are so strongly interwoven that subdivision is very arbitrary. One such division could be the following:

1. The approximation of terrestrial environment,
2. Biophysical and pharmacological aid to overcome or partially compensate for the alien environment,
3. Psychological considerations,
4. Prevention and alleviation of pathological problems.

We shall discuss the above parameters quite elastically and show the main fields of interest and their interaction, without attempting to deal with the problems involved nor to go into great technical details.



• **Artificial environment**—Although the assignment of proper values of importance is not possible, obviously the first item should be the artificial environment of the crew compartment.

An ideal environment, however, would suit "ideally" only the "average man." But we know that there is no "average man" thus the "ideal environment" is only an approximation and must have a significant spread to fit even a selected group of Western men. With these restrictions we can write the following set of factors:

Temperature: 68-72°F
Humidity: 40-50% R.H.
Acceleration: 0.8-1.2 G
Altitude: 900-1000 Millibars
Oxygen partial pressure: 18-21%
Carbon dioxide content: 0.3-0.5%
Ozone and atmospheric pollution: 0
Nuclear radiation (ambient flux): Less than 300 Milliroentgen/week
Ambient illumination: 5 Millilambert
Ambient random noise: 2 db
Air movement: 2 ft/sec and 100 ft^3/min
Clothing: Short sleeves
Minimum living space: 650 cft per capita

Any, even slight, deviation from the "ideal environment" places a stress on the individual. One of the prime functions of space medicine is to study the stress tolerance of the human organism and to find methods to adapt the ecosystem of the crew compartment to the human limits. Another task is to find pharmacological, biophysical and psychological means to extend the human tolerance limits to environmental stress.

• **Approximation of terrestrial environment**—For the near future and from the point of view of the operational integrity of the space crew, it would be ideal if the ecosystem of the crew compartment were identical to or just slightly divergent from the best terrestrial conditions. It is quite obvious that the provision of such conditions would be very expensive and in

Philco Ground-Space Communications System commands and tracks **DISCOVERER** satellite

DISCOVERER . . . the United States' newest earth satellite . . . is opening new vistas on the frontier of outer space. And Philco is proud to play an important role in this renowned achievement as a part of the Discoverer Team . . . in conjunction with the Lockheed Aircraft Corporation and the Air Force at the direction of the Advanced Research Projects Agency of the Department of Defense.

As the subcontractor for Discoverer's entire communications system, Philco designed and developed the vast complexity of ground-space communications, tracking, commanding and data gathering and processing systems.

The Philco-designed and equipped system observes and commands Discoverer through a series of five tracking and data collection stations in Alaska, California, Hawaii and a specially equipped ship at sea. Philco continues its participation in the Discoverer Program by assisting in the actual operation and maintenance of the communications and data handling network.

Philco's part in the Discoverer Program is typical of the many and diverse advanced research and development activities being conducted in our laboratories on the East and West Coasts where outstanding career opportunities abound for Engineers, Mathematicians, and Physicists.

In the wonder-world of advanced electronics, look to the leader. Look ahead . . . and you'll choose Philco !

Kelsey-Hayes thrust vectoring systems give missiles proper directional control.

Kelsey-Hayes is contributing substantially to the design, development and production of new thrust vector control systems for solid fuel propulsion.

For example Kelsey-Hayes, in a recent crash program, designed and fabricated a movable nozzle control that passed static firing tests for one of the newest sophisticated missile systems.

The swivel nozzle control is just one of the latest developments by Kelsey-Hayes as a subcontractor of propulsion subsystems, flight componentry and high performance materials. Spearheading Kelsey-Hayes activities is the Advanced Design Group, a flexible team of experienced design specialists. Kelsey-Hayes Company, Detroit 32, Michigan.

environment same as earth's . . .

many cases technologically impossible. Therefore the crew members will have to be satisfied with conditions that will differ strongly in many parameters from, what we may term, best laboratory conditions. It is in the realm of space medicine to provide the quantitative analysis for the maximum deviation from the ideal environment without causing significant performance decrement in the crew. For example, if the ambient temperature of the crew compartment is 75 to 77°F the crew will still be able to perform its duties without too much fatigue or discomfort. But should the temperature go to 85 or 90° the mission profile of the individual crew members must be radically changed due to the early deterioration of their work output.

Special emphasis must be given to multiple stresses. We must study thoroughly what effect deviation from the ideal conditions in more than one environmental parameter will have on the performance of certain psychomotor tasks. The main reason for this is that in physiology and psychology multiple stresses are not additive but may influence the result by factors of 2 or more. Not only are these multiple stress factors non-linear but the performance of the crew is further complicated by other dependent variables such as the non-linear human gain control. The complexity of the question of human performance under multiple environment stresses is such that it cannot be computed or even closely approximated. Therefore research must provide the necessary information.

There is a wealth of information available in the literature on the endurance and work efficiency of a human exposed to individual environmental stresses. For illustration, let us consider the effect of peak acceleration on human transfer functions. In the relatively new science of ergology, that is the study of the human work output, the human transfer function is defined by the speed and accuracy by which the human organism translates a sensory stimulus into muscle action. As an example, the subject is indoctrinated that upon the flash of a red light he should punch a certain button with his right index finger.

Space flight has given great emphasis to the study of the effect of acceleration on the human performance. Since the pioneering work of Col. John Stapp valuable information has been gathered with the high performance human centrifuges operated by the Navy in Johnsville and by the Air Force at Wright Air Development Center in Dayton. The question of the human performance under acceleration stress has a number of parameters:

1. Direction of the acceleration force,
2. Peak acceleration,
3. Duration of the acceleration.
4. Rise time to peak acceleration.

• **Man under stress**—The human capability of performing a certain psychomotor function while exposed to acceleration stress can be shown by a three-dimensional graph (Fig. 1). On the transparent plate in the center of the illustration, a mannequin is fastened in such a position that the so-called transverse g-load shows horizontally and the vertical measures the positive and negative acceleration in g's. The third dimension, on a logarithmic scale, represents the rise time to peak g-loads. The shadows cast on the vertical and horizontal planes break the three-dimensional graph down into two two-dimensional illustrations.

We learn from this graph that with fast rise time the human operator will be operational only if exposed to very little acceleration. If the peak g-load is reached between a half and one second, the performance will be satisfactory even if the operator is exposed to a transfer g-load of more than 20 g's. But if the rise time is prolonged to 10 or 100 seconds, the performance radically decreases.

This strange behavior of the human organism can be explained as follows: With fast rise time to peak g-load, the impact or shock effect will set a limit to the proper human performance because time is needed before the muscles will compensate and the nervous system can coordinate muscle action. On the other hand, if the rise time is relatively long, then factors involving the rate of blood flow in the arteries and veins come into play. Much research is required for the understanding of this new field of hemodynamics. The flow of blood can by no means be compared to that of water in a system of iron pipes. Blood is a non-Newtonian liquid that does not behave as water. The arteries are pipes or tubes that are pulsing or changing their diameter. Their walls can be influenced by emotions. Obviously, we cannot make predictions based on computations for a system so complex. However, we can gather the necessary information by research.

We have here discussed only a small fraction of one of the parameters of the space equivalent environment. The other parameters cover the whole range listed in the earlier portion of this paper. In addition, there are the metabolic needs of solids, liquids and gases, waste disposal and hygiene. We can only throw a spotlight on fragments of space medicine in this paper to outline its scope.

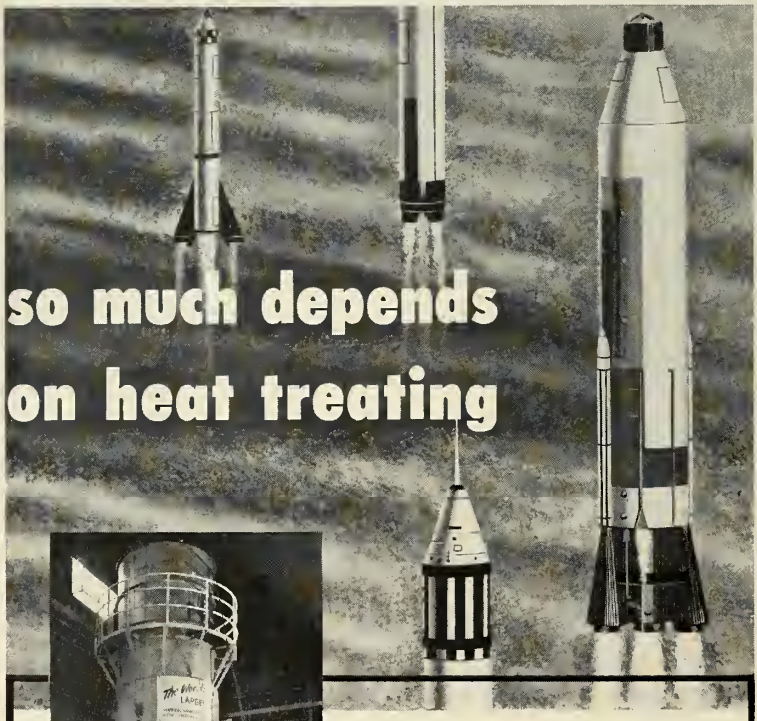
• **Biophysical and pharmocological assistance of the space crew**—It was obvious from the beginning that for technological and economic reasons the ecosystem of the space capsule cannot be perfect. Therefore, the crew must be assisted to overcome or partially compensate for the alien environment. A number of difficulties will arise due to the weightless state during the coasting of the vehicle, which may last for weeks or months. Many symptoms caused by zero-gravity in the human organism can be predicted and certain countermeasures can be taken. The effect of zero-gravity of long duration can, however, only be studied when a man is placed into a satellite.

The establishment and the problems of the various cycles of the human ecosystem in the space capsule, such as the food cycle, the water cycle and the respiratory gas cycle can also be considered as a part of space medicine. For shorter flights, such as a moon mission, such commodities as water, food and oxygen can be carried from earth. For longer lasting missions, however, a re-cycling of food, water and oxygen is inevitable. The problem with the re-cycling of water is more or less solved. The utilization of unicellular plants, such as algae, for oxygen production and carbon dioxide elimination is under study. However, the utilization of photosynthesis for this purpose is very cumbersome.

Food for the crew poses a knotty problem. Due to weight considerations, it should be completely digestible. But we still do not know whether the human digestive system can adapt itself to a bulkless food without severe symptoms. If all the food is absorbed in the stomach and in the first turns of the duodenum, the emptiness of the major part of the digestive system may cause permanent hunger sensations. These in turn could build up nervousness and irritability to a degree where the whole mission might be seriously jeopardized. Possibly, medication could counteract such symptoms.

The excellent adaptability of the human organism makes for further concern. During a flight lasting months or perhaps years, anatomic and physiological changes would occur in the bodily functions. After return to earth, crew members would have to undergo very long lasting re-adaptation to terrestrial conditions. The problems aris-

ing in this connection are considerable. Since space navigation will require much skill and patience, the returning experienced crew will have to be used for new missions. But the adaption to space-equivalent conditions and the re-adaptation to terrestrial environment may be so uncomfortable that the crew will be reluctant to undergo the same experience again. In the present cultural and social structure of our society, it is unthinkable that the crew that signs up for a space mission should never be permitted to return to earth. This is another difficulty we must overcome.



• **Psychological considerations**—It is evident that space medicine must maintain the mental health as well as the physical well-being of the crew. The psychological problems associated with space flight are at least as severe as the physiological problems. Most problems revolve around the two main fields of fatigue and anxiety. Both of these factors and related ones can and would handicap the crew performance. There is where a new science, psychopharmacology, has a most promising field of application. This leads directly into another aspect of space group-psychology, namely the proper control of group interaction in the society of the crew compartment. It is obvious that means have to be found to optimize the cooperation of the crew members and to eliminate every element which may cause friction or hostility. This can be achieved by the proper combination of crew selection, indoctrination, training and again the application of psychopharmacology.

• **Prevention and alleviation of pathological problems**—It is of great concern to space medicine how to prevent malfunction of the bodies of the crew, or if it cannot be avoided how to cure them. Everybody will agree that a toothache of a crew member in a space craft could cause a severe situation. On the other hand, it is unlikely that complete dentistry equipment, can be carried in the vehicle or that a prerequisite for signing up for a space crew would be to pull all teeth. Although the crew and the crew compartment would be in a sort of semi-sterile state this, however, would not prevent the occurrence of a cavity and a subsequent inflammation with its severe consequences if left without care.

The probability that any of the crew members would suffer appendicitis is low under the prevailing conditions. Nevertheless, provision has to be made that in case of its occurrence the crewman should not be left to die. This raises the question of how far crew compartments should be equipped with surgical facilities.

The avoidance of contagious diseases can be achieved by proper pre-flight treatment of personnel and equipment. Yet it is conceivable that some of the harmless micro-organisms, such as the coliform bacteria in the intestines, may mutate under the influence of cosmic radiation and develop a strain that could cause severe symptoms and incapacitate the crew. These mutant bacteria might resist most of the antibiotics. Such an organism could be isolated and a life-saving serum could be developed if the necessary facilities were available. But it is quite unlikely that serum production could be incorporated into the payload. Thus space medicine also must decide on and coordinate with the mission profile the materials and equipment needed for safeguarding the bodily and mental health of the crew.

It is apparent from the foregoing that space medicine touches on all the fields of astronautics. When man is put into the space vehicle, all of its parameters must be adjusted to make the vehicle livable. Propulsion, the air frame, guidance, communications and engineering must be modified and new specialties must be developed to meet the peculiar needs of the human organism. Thus space medicine is a science that stands astride the disciplines.

Every step in the fabrication of a missile is critical. All the more reason to turn to the expert in precision heat-treating, when your mission in research, development or production requires heat-treating support.

At Metallurgical, Inc., experience combines with facilities to achieve results which meet your close dimensional tolerances and rigid specifications.

DELIVERED—thousands of missile APUs

. *Solid propellant—hydraulic output* **2.** *Liquid propellant—hydraulic and electric output* **3.** *Solid propellant—electric and mechanical drive output*
4. *Liquid propellant—hydraulic and electric output* **5.** *Solid propellant—hydraulic and electric output*
6. *Solid propellant—hydraulic, electric and steering outputs*

AiResearch has designed, developed, manufactured and delivered thousands of missile accessory power units. Extremely reliable and lightweight, these various solid and liquid monopropellant APUs are completely self-sustaining within the missile system. Designed to minimum space and weight requirements, they are built to withstand high G loading and severe temperature extremes.

The several units pictured above provide hydraulic, electrical and/or steering surface control depending on the customer's requirement. Delivered horsepower ranges from 1.2 to 35 h.p. over hot gas operating durations from 30 seconds to 20 minutes. Electrical regulation is maintained as closely as ±½%. A significant advance in missile APUs is unit #6 pictured above. This package represents the first integrated hydraulic and electrical power unit providing a steering surface actuation system.

These tailored systems utilize the extensive hardware experience and complete laboratory, test and production facilities of AiResearch needed for quick and efficient quantity production of complex APU systems. AiResearch is the world's largest and most experienced manufacturer of lightweight turbomachinery — the key component of its APU systems. Your inquiries are invited.

Missiles launched from ocean depths

ft *"Operation Sky-Catch" tests,* conducted jointly by S Navy, Westinghouse and Lockheed, reveal effects of r n stresses. To prevent damage to POLARIS test missile m onents, huge overhead assembly catches it in mid-air.

r **eft:** *Carrying awesome destructive power,* Navy's OL RIS is markedly smaller than other U. S. ballistic iss es of same range. To enable one submarine to carry an missiles, Lockheed scientists achieved miniaturi- tic breakthroughs on all major systems of POLARIS.

Above: *Propulsion system firings* light up night sky at Lockheed Missiles and Space Division's 4000-acre test base in the Santa Cruz mountains, Calif. A nearby vertical test stand permits simulated flights of complete POLARIS missiles, to test their propulsion and guidance systems.

Left: *Nuclear powered U. S. Navy sub* (1) launches solid-propellant POLARIS missile which erupts from ocean depths (2)—then rockets its way on a ballistic missile trajectory high above the earth's atmosphere (3) into outer space. Re-entering the atmosphere (4) the re-entry body of the POLARIS plunges earthward to destroy its target (5).

Launching an IRBM from submerged submarines involves technological developments that are unique in ballistic missile history.

As POLARIS Missile System manager and prime contractor, Lockheed's Missiles and Space Division is responsible for coordinating all phases of its design, development, and production.

The POLARIS, a solid-propellant missile, will be operational in 1960—ahead of schedule. The operational missiles will be delivered to U. S. Navy submarines in Lockheed ready-service transporters under controlled humidity and temperature conditions. And Lockheed's ACRE—Automatic Checkout and Readiness Equipment —will maintain the constant ready-to-fire capability of POLARIS missiles, right up to the moment of launch.

With an ultimate range of 1500 nautical miles, the POLARIS will become one of the most formidable deterrent weapons ever devised. For any significant military target on earth will be within range of its nuclear warheads.

Industry Faces Tough Assignments

by David R. Hull

WALTHAM, MASS.—Accelerated study, research, and development brought on by the advent of *Sputnik* have caused daily advances in the vast and unsettled field of space and missile technology. Electronics is contributing immeasurably to these developments.

A quick examination of the space vehicle itself will determine the role that electronics is playing in the space activities during the current "first generation" of space technology. The rocket-powered flight vehicle contains four basic elements: the airframe, the rocket engine, the propellant, and the payload. And electronics varies from slight to dominant in degree of importance to these elements.

The industry has less impact on the airframe portion than on the engine and propellant because electronics provides only control of these elements. Not so regarding the payload—the main area of interest.

The possible use of ionized propulsion for thrust directly concerns the electronic industries to the extent of the need for electrical power generation and control devices. The payload, on the other hand, contains the electronic sensing, recording, storing and transmitting segment that is able to reach regions previously inaccessible and gather scientific data heretofore unobtainable. This element consists of TV cameras, infrared detection devices, radar gear and data recording and storage equipment. Putting the payload into orbit is the sole purpose of all the other elements of the space vehicle.

• **Guidance**—Without guidance, however, the space vehicle cannot fulfill its mission, and without electronics there can be no guidance. Guidance operations consist of the measurement of vehicle position and velocity, computation of control actions necessary to properly adjust position and velocity, and the delivery of adjustment commands to the vehicle's control system. Guidance operations may occur during the vehicle's take-off, during flight in space, or during the vehicle's return to earth.

Space-flight missions in the immediate future will use ballistic rockets, and the electronic guidance of such vehicles will be extensions of current ballistic missile guidance techniques. "Ascent guidance" for such missiles is used only during powered flight. The electronic guidance system determines the free-flight path.

When the desired combination of position and velocity is reached, guidance systems signal cut-off of the propulsion systems. Electronic control of this function is vital.

• **Margin for error**—The classic example is that an ICBM at a range of 5500 nautical miles will have an "impact miss-distance" in the direction of flight of about one nautical mile for an error of one foot per second in the magnitude of its cutoff velocity. At the same one foot per second error in magnitude of velocity at thrust cutoff, the miss-distance to the moon is 20-100 nautical miles, and to Venus it would be about 25,000 nautical miles.

Using modern electronic components and techniques, inertial guidance is accurate enough in most instances to establish earth satellites. Placing payloads on the moon's sursface and establishing satellites around the moon, however, requires refinement in such control techniques. Travel to the other planets of the solar system, on the other hand, will demand mid-course and terminal guidance systems to avoid the miss-distance.

Near-to-earth mid-course guidance can be executed with our present electronic navigational ground networks. But flights substantially far out in space will require a guidance capability in the vehicle itself. Such mid-course guidance will require measurements on board the spacecraft using such electronic instruments as radio telescopes, TV cameras and infrared sensing equipment.

These devices will base their measurements on star or planet sightings. Additional electronic instruments are necessary to compute suitable control actions and to signal operations to the rocket engines. Speed and reliability of equipments during these operations are mandatory.

Terminal guidance systems will require infrared radiation detection equipment and radar systems. Such radars employ repeater transmitters in the rocket, a ground computer, and a radio command link to the vehicle.

• **Communications**—The industry faces a stiff assignment in providing communications in space. Electronic equipment is needed to cope with strange space environments, severe size and weight limitations in space vehicles, large communications ranges and extreme requirements for lengthy unattended operations.

The industry is actively investigating countless possibilities for communications associated with space flight in such areas as electrical energy and power sources, radio frequency power innovation, data storage and data encoding, and receiver sensitivity. A 10-to-1 reduction in receiver noise is expected through the development and use of ultrasensitive devices such as cooled detectors and masers.

Highly directional space vehicle antennas will improve communications and achieve power savings. Successful operation of this system depends upon attitude stabilization of the spacecraft. This is another area of present electronic research and development. Radio astronomy, the air-defense surveillance net and current space flight tracking activities are building up a backlog of experience in the use of very large steerable ground antennas which will

About the Author

David R. Hull is vice president of the Raytheon Co. and president of the Electronic Industries Association. A retired electronics engineering officer and captain in the U.S. Navy, he has been an electronics industry executive for 10 years.

Hull, as a pre-war assistant to the director of the Naval Research Laboratory, coordinated the Navy's radar research and development program. During World War II, he had charge of design and development of radar, sonar, special electronic applications and countermeasures essential to naval operations. He directed the Federal Telecommunication Laboratories of the International Telephone and Telegraph Corp. for two years after he retired in 1948. Hull has been with Raytheon since 1950.

be needed to support space missions.

• **Reliability**—In communications as well as in other electronic space activities, further miniaturization, improved packaging of components and increased reliability is mandatory. Electronic gear must have a high degree of reliability to guarantee output not only for the duration of flight but also for a useful period after arrival in space or impact on a planet.

Keeping equipment working unattended for many months is possible. But the industry finds it requires careful design, extensive testing, and knowledge of the environment in which it will operate. This unquestionably will lead to the use of improved basic materials.

• **Observation and tracking**—Observation and tracking are other tasks that electronics must perform in this Space Age. Various forms of ground-tracking radio, infrared, and optical systems will be required by all space missions in order that vehicle trajectories may be observed and monitored from the earth. The rotation of the earth and the nature of the vehicle's trajectory and orbit generate a requirement for locating tracking stations around the globe. In addition, ground facilities containing electronics will be required for control, landing, and recovery of vehicles.

• **Infrared measurement**—Infrared detection systems mounted in space vehicles are playing a vital role in space exploration. Electronic sensors that measure infrared radiation have permitted man to understand the composition of the atmospheres of the planets and other celestial bodies. The obvious advantage of such probes is that scientists for the first time are able to examine the outer reaches of space without the hampering effects of earth's intervening atmosphere.

Electronic observation of the earth's atmosphere from an orbiting vehicle will permit measurements of cloud cover, water vapor and carbon dioxide concentrations, thus aiding meteorological observations. Infrared sensors in spacecraft will have utility for military reconnaissance and surveillance of the earth. In particular, especially large sources of infrared energy such as afterburning engines of supersonic vehicles and exhaust flames of ballistic missiles may be detectable from orbital platforms. When combined with spectral analysis, infrared sensors would permit clear identification of a planet which will assist the navigation and terminal guidance of space vehicles.

• **Accomplishments**—The electronics industry can boast of many accomplishments in space and missile technology. For example, miniature TV systems for satellites are being developed now to broadcast pictures to

THE GRAND CENTRAL REPORT

Since merging with Food Machinery and Chemical Corp. and Tennessee Gas Transmission Co. a year ago, Grand Central Rocket Co. has developed an organization of highly competent management and efficient modern facilities. FMC and TGT have set as their goal building GCR into one of the strongest, most capable solid propulsion organizations in the country.

With over 500 employees, this seven year old organization (a veteran in this business) has some 200 engineers and scientists with an average of over eight years of experience in solids.

This able group has been augmented with the addition of Mr. John J. Crowley, former director of the Office of Guided Missiles, Dept. of Defense, as Vice Pres. for Project Management and Marketing; Mr. G. R. Makepeace, technical director of propulsion for Polaris, as Vice Pres. for Research and Engineering; Mr. Albert T. Camp, formerly Head of the Propellants Division, NOTS, as Asst. Vice Pres. and Dir. of Research; Mr. G. Daniel Brewer, of the Minuteman missile program, Space Technology Labs, as assistant to Mr. Crowley; Mr. George Cushman, former staff specialist in the Office of the Dir. of Guided Missiles, as Dir. of Marketing, and others.

At this moment the Company has a capacity of 700,000 lbs. of propellant a month to place at the disposal of the Nation's rocket program.

GCR now has the *know-how, men, facilities, financial background,* and the *management capability* to undertake successfully any solid propulsion development and production foreseeable in the Nation's military and space program.

It has a planned standby available *now*—a strong complement of engineers, scientists and support personnel to undertake these programs at once. They are now engaged in company sponsored work on propellants, thrust control, and reliability assurance to advance our knowledge and be ready with new and valuable ideas when called upon. They will not have to be taken off other important projects.

If you have an application requiring a seasoned team of men and facilities to counsel you, to participate in your advanced concept studies, or to start immediately on a new development, contact GCR for a prompt response.

NEW VOUGHT PROJECTS OFFER CAREER APPEAL TO CREATIVE MEN

Space, ASW, and weapon system work at Vought requires continuous R & D in methods and materials, structures and design. These projects have prompted exploratory work in the following areas:

Structures (Supersonic and Hypersonic)
Heat transfer, thermal stress and deflection analysis, and stress analysis using high-speed computers.

Manufacturing R & D
Welding and brazing of super alloys and exotics; advanced forming and cutting studies; prediction of metal fabricability.

Industrial Engineering
Project estimating, work sampling, line load and balance, and packaging and installation of new procedures.

Antisubmarine Warfare
Studies of detection and classification techniques involving Acoustics, Geomagnetism, Geophysics, Electromagnetics, Electrochemistry, Math.

Engineering Planning
Man-hour and budget forecasting, and project planning and scheduling.

Product Design
Automatic escape devices, atmospherically sound cockpits and advanced instrument displays for space pilot, crew.

Flight Test Instrumentation
R & D in new techniques for electronic gathering and reducing of flight test data.

Aerodynamics
Wind tunnel and model work employing Vought's 3,800-mph high-speed wind tunnel and new "high-temperature" laboratory.

Qualified applicants are invited to write:

J. W. Larson
Ass't Chief Engineer, Administrative Dept. P-14

CHANCE VOUGHT
DALLAS, TEXAS

earth receivers as far away as one thousand miles. These systems are designed to operate for several years. Also, electronic data recording and reduction devices are improving in speed and reliability. Recent developments in the *Vanguard* data reduction facilities may speed up the processing of data two and a half times over the rate at which the data is gathered and received. This system is expected to study up to 10 million items of recorded and processed data telemetered by radio signals from the satellite—resulting in improved flight control of guided missiles and space vehicles.

The planet Venus has recently been contacted with use of a solid-state maser in a practical radar system, verifying that interplanetary communication is possible. Another accomplishment has been the discovery that about six satellites can provide coverage for navigation of the seven seas. About six communication types can provide reliable communications anywhere on earth. Infrared detection equipment is now sufficiently advanced to track satellites hundreds of miles away.

Transistors are employed increasingly in spacecraft. The development of micro-miniaturization solves the size and weight limitations posed by space vehicles. Solar cells, too, are playing an important role in furnishing power over a long period of time in satellites. By their means the energy for generating electrical and electronic devices is obtained from the sun.

• **Second generation**—As the Space Age matures, the electronics industry will find itself more closely involved in space activity. Improved electronic and scientific techniques will have initiated a "second generation" of the Space Age by making it possible for man to be sent aloft in earth-circling satellites. Greater sophistication will create the need for more refined electronic instrumentation and control equipment. For example, the vehicle will carry with it a life-sustaining environment and if the time of flight is to be extended over a long period of time then total regenerative air, water and food cycles are the only answer. Electronics, too, may control the processes of the cycle of photosynthesis reliably and automatically. Electronics will be employed in maintaining the delicate balance of secondary living organisms that will be required in the reconversion of wastes into nutrients, and electronics will guard against leakage of vital materials through detection equipments.

Also, controlling the rotation of the space vehicle which induces artificial gravity may be another important function of electronics.

The industry will be called upon

VOUGHT WILL BUILD NASA SPACE ROCKET

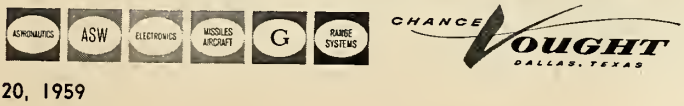
Scout is the name of a new four-stage rocket to be used in NASA research. It will boost 150-pound satellites into earth orbit and fling 1,000-pound instrument probes as far out as 5,000 miles. The beauty of *Scout* is that it will do these things at relatively low cost—about $500,000 per vehicle, according to NASA.

Chosen to build this new approach to space research is Chance Vought's new space development team. This group already has come along fast in areas such as fitting man to a space machine, providing him escape devices and instrument displays.

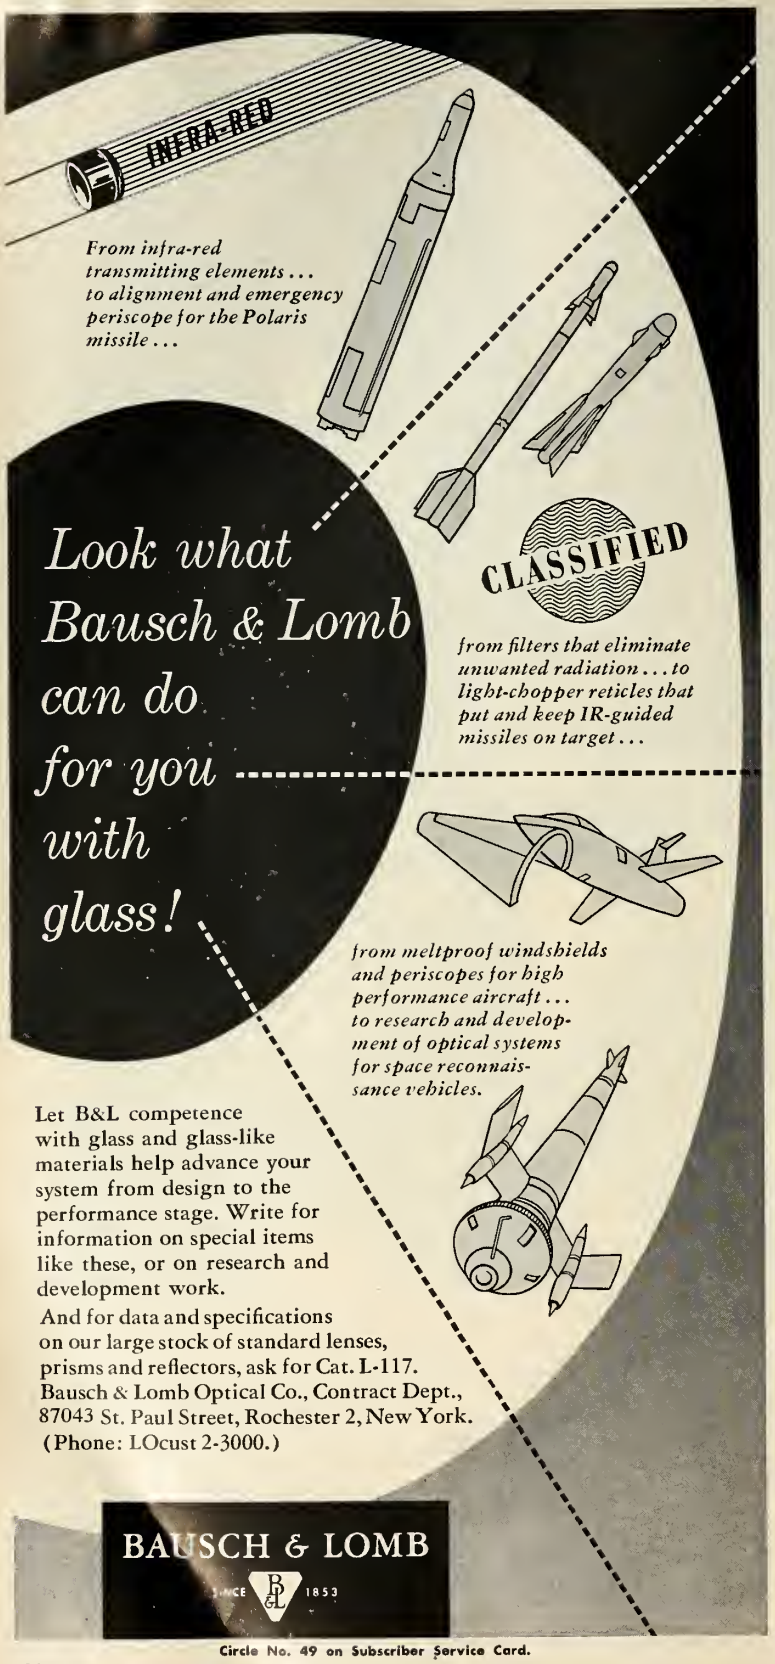
For example, in Vought's unique orbital flight simulator, NASA and company pilots have already "flown" by the new rules of space, using the same family of instruments the first space navigators will use.

Designing for spacemen is new to Vought, but exploring unknown regions isn't. For more than 40 years, Vought has worked on the frontier in the "human factors" of aircraft design. Matching man to aircraft, the company has pierced imposing barriers to higher and faster flight. Matching man to spacecraft, Vought will continue to extend frontiers.

Astronautics is just one in the broad spectrum of Chance Vought fields of activity. Other areas include: design and production of high-performance missiles and aircraft, antisubmarine warfare, electronics, advanced weapons, range systems management, advanced control computer systems.



CHANCE VOUGHT
DALLAS, TEXAS



America's civilian space agency proves

IT'S GOOD BUSINESS TO EXPLORE SPACE

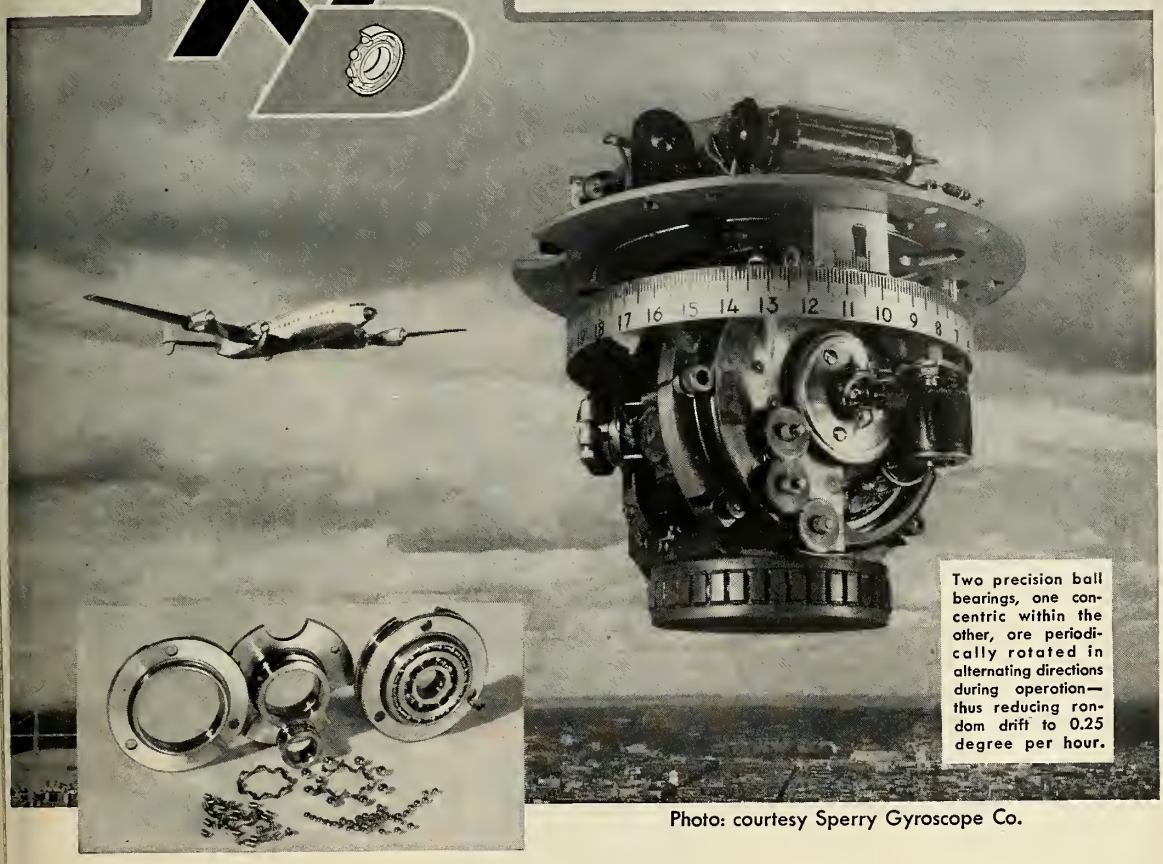
Weather forecasts hatched in space will save billions of dollars a year. Satellite transmitters will beam our television programs around the world. In these and other ways, space will pay back the money spent on exploration. Making facts out of these forecasts is part of the job of the National Aeronautics and Space Administration, the engineer-scientist agency that manages U. S. non-military aerospace programs. NASA adds a condition to predictions of a world space-trade boom: space, itself, must remain free. This freedom, NASA men know, depends on whether America leads or lags as a space explorer.

Circle No. 49 on Subscriber Service Card.

to an increasing degree to perform vital functions in the space and missile programs. It has already provided devices necessary for missiles and satellites even with limited payloads. The industry can and will keep abreast or ahead of the Space Age requirements including those sensing and control mechanisms which will be needed for manned space explorations.

But in all its efforts to help solve space and missile problems, the industry has not forgotten that many of its past military developments have been successfully converted to peacetime use. The industry envisions that new and expanding markets will evolve from the application of Space Age technology to production for commerce, industry, and the consumer.

• **Commercial application**—This impact will be felt more distinctly in commercial and public service activities. One television transmitter can serve a continent. Electronic devices placed in orbit will forecast the weather, aid ships in navigating any seas around the earth, improve world-wide communications by serving as relay stations for signals and permit long-range point-to-point communications at low levels—thus helping to conserve the already crowded radio frequency spectrum. In addition, satellites containing electronics will patrol for icebergs, warn of forest fires, map the earth's surface, and conduct geological surveys.



In the industrial area, automatic control devices are using advanced equipment and component designs that have been brought about by Space Age demands. Reduced costs and greatly improved product quality are seen resulting from these changes.

The impact of the Space Age on consumer electronic devices is apparent. One only has to observe miniaturization techniques in radios and other devices to see the relationship between consumer product compactness and the requirements of space technology.

Increased reliability is another by-product of Space Age design that will continue to enhance electronic products in all market areas.

Because Space Age concepts are stimulating academic study, the gap between advanced ideas for the use of electronics and the level of present laboratory and production techniques may widen. It is also conceivable that this problem may be complicated further by the accumulation of new knowledge about our world and the universe made possible through orbital observations. Therefore, it is necessary that the electronics industry encourage the development and improvement of laboratory techniques and facilities that will convert new knowledge into useful functions for everyday living.

CASE HISTORIES

Two precision ball bearings, one concentric within the other, are periodically rotated in alternating directions during operation—thus reducing random drift to 0.25 degree per hour.

Photo: courtesy Sperry Gyroscope Co.

1,200% Gain In Gyro Accuracy With N/D Ball Bearings

CUSTOMER PROBLEM:

Get new, advanced gyro bearing design "off the board" and into production. Sperry Gyroscope Company, in developing its new Rotorace (TM) gyro, designed a special bearing capable of "averaging out" error-producing effects of friction on sensitive gyro gimbals. New manufacturing techniques would be required to achieve high degree of precision required by Sperry design.

SOLUTION:

N/D Engineering, when approached by Sperry, created special manufacturing techniques for the high precision production of these unique piggy-back gimbal ball bearings. Used in the Rotorace design, the bearings helped achieve reduction of the gyro's random drift rate. The 2 or 3 deg. per hour drift, recently considered very good, is now cut to as little as 0.25 deg. per hour, with still lower rates in sight. Another example of New Departure's ability to meet exacting instrument bearing requirements through broad engineering experience and precision manufacturing techniques.

For immediate engineering analysis of your current high precision instrument and miniature ball bearing problems, write New Departure, Department K-7.

Considerable Theoretical Work Underway

Results are encouraging but experiments still are in the beginning. Here is the state of research, expected performance and the technical problems.

by Ernst Stuhlinger

HUNTSVILLE, ALA.—The use of electric propulsion devices will be restricted to low-acceleration systems operated in empty space. Wherever these restrictions can be accepted, electric systems may prove advantageous because of their very favorable payload-to-takeoff mass ratios. The successful launching of satellites and lunar probes, and numerous study projects on lunar and planetary exploration, stimulate more and more interest in such propulsion systems. Experimental work on electric propulsion is presently under way at many places, sponsored both by government agencies and by private companies. The National Aeronautics and Space Administration recently established a powerful experimental working group for electric propulsion at the Lewis Flight Laboratory.

The possibility of using electrically accelerated particles for space vehicle propulsion was mentioned probably first by Goddard and by Oberth. Basic features of ion motors were discussed in several papers by others during the period from 1948 to 1954. A design study of a complete ionic propulsion system, published by the author in 1954, pointed out that the design and construction of a system using cesium ions should be feasible with presently available technical knowledge. In the meantime, a considerable amount of theoretical and experimental work has been accomplished with the result that electrical propulsion systems appear very promising for a number of applications. The present paper attempts to give a brief account of the state of research, of expected performance figures, and of existing technical problems. The discussion will be limited to ionic propulsion systems; arc-heated and plasma systems will not be considered.

NASA'S MODEL of a hypothetical spacecraft equipped with the components of a nuclear rocket propulsion system.

• **Basic components**—In contrast to chemical rocket engines, electric propulsion systems require a separate source of energy. The only two sources that appear promising today are the sun and a nuclear fission reactor. In both cases, the magnitude of the energy-producing system aboard the space vehicle is dictated by the power level rather than by the total energy. The crucial figure is the power-to-weight ratio of the powerplant, α, measured in kw per kg. Several schemes to transform solar or nuclear heat into electrical power will be discussed later. With presently available technologies, the power-to-weight ratio α is still the figure that influences the thrust-to-weight ratio of electrically propelled space vehicles more than any other factor. Only a fraction of the heat produced by the powerplant can be transformed into electrical power.

The greater part must be absorbed by a heat-exchanging fluid, carried to a radiation cooler, and radiated into space. A large, low-temperature radiation area would be desirable from the standpoint of thermodynamic efficiency; however, a small, high-temperature radiator would lead to a smaller powerplant weight. The best size and temperature of the radiator will in any case be the result of an optimization study, which must also consider such factors as meteorite damage, corrosion effects and repair possibilities.

It may be advantageous to rotate the radiation cooler, and possibly the entire powerplant system, in order to cause the coolant to flow in the desired direction under the action of centrifugal forces. The propellant for electric propulsion systems must lend itself to easy ionization; it should have a large m/e ratio, and good storage properties. Depending on its mission, an electrically propelled space vehicle will carry an initial amount of propellant of the order of 10 to 50% of its total take-off mass.

• **Avoid feedback**—The ion motor, comprising ion source, accelerating chamber, electron emitters and beam neutralization system, will require

About the Author

Dr. Ernst Stuhlinger is director of the Research Project Laboratory, Development Operations Division, Army Ballistic Missile Agency, Huntsville, Ala. Born and educated in Germany, Dr. Stuhlinger was assistant professor of physics at Berlin Institute of Technology for five years before the outbreak of World War II. During the war, he was engaged for three years in nuclear physics research and then went into missile development at Peenemunde in 1943. He came to the U.S. in 1946 and worked on missiles at Ft. Bliss, Tex., and White Sands, N.M., until he went to Huntsville in 1950.

Air Force "Sunday Punch" ATLAS

Boosted into space by the fiery thrust of three huge rocket engines, the seven-story Atlas intercontinental ballistic missile roars upward from its Cape Canaveral launching pad. Quickly it sheds the frost encrusting the liquid oxygen tank and races to its predetermined destination in the far reaches of the globe. In its size and range and capability, the Air Force Atlas is a commentary, for all the world to heed, of the necessity to maintain the peace. RCA's Missile and Surface Radar Department has been privileged to design and develop ground check-out, launch control and cabling equipment as a major subcontractor to Convair (Astronautics) Division of General Dynamics Corporation, the Atlas prime weapons systems contractor.

limited number of ion sources . . .

more development work than any other component. The ion source should have a high efficiency close to 100%; sputtering and erosion of electrodes must be avoided; the current density, limited by space charge effects, should be at least several mA per cm^2; electrons must be injected into the ion beam to form a neutral plasma, but any backflow of electrons into the ion source must be prevented.

A large number of ion sources were developed during the past decades, but only a few of them are suitable for electric propulsion systems. The contact ionization of alkaline atoms on hot tungsten surfaces is unsurpassed by any other source with regard to simplicity, high efficiency, and long operating life. The tungsten may be replaced by other metals of large work function and high vaporization temperature. The surface may be presented by a wire or ribbon grid, a woven structure, or a porous plug. Cesium, as the heaviest non-radioactive alkaline element and the one with the lowest ionization potential, would be the best choice. Metallic cesium is still relatively expensive at present, but indications are that its price will come down as soon as the demand for larger quantities rises.

Higher ion current densities may possibly be obtained from pinched-arc sources of the "duoplasma" type proposed by M. V. Andrenne. Ions of many kinds of atoms and molecules are readily produced by this source. Before its suitability for ionic propulsion systems can be appraised, more details about ionization efficiency, cooling requirements, erosion resistance, and operating life time must be investigated.

• **Beam neutralization**—The limiting influence of space charge effects is encountered twice in an electric propulsion system. First, these effects govern the density of the current between ion source and the accelerating electrodes; and second, they restrict the flow of the jet from the accelerating electrodes out into space. The current density inside the ion source and the accelerating chamber is a function of the accelerating voltage, and of the spacing between ion source and accelerating electrode. It appears that ion current densities as high as 5 to 10 mA cm^{-2} may be obtainable.

Space charges within the outgoing ion beam would render the formation of an ionic exhaust jet impossible unless at least the greater part of the positive charges were neutralized by negative charges. The situation is somewhat relieved by the lateral dispersion of the beam, which decreases the current density. However, injection of electrons into the ion beam will be necessary.

A considerable amount of theoretical work dealing with this problem has been done recently. The results are encouraging, but experiments are still in the beginning. The electrons most probably will be injected at low speeds into the beam, and will then begin to oscillate laterally through the beam, with a longitudinal velocity component of the order of the ion velocity. One proposal suggests that expendable surfaces be exposed to part of the ion beam; when striking the surfaces under grazing incidence, each ion knocks out numerous low-energy electrons, which then mix with the beam and contribute to its neutralization. The surfaces would be renewed as they are consumed by erosion.

• **Accelerating voltage**—The optimum accelerating voltage is a function of the mission under consideration, the specific power of the powerplant, the m/e ratio of the propellant particles, and the total available power. For cesium ions, it will be of the order of 3000 to 10,000 volts. From the standpoint of a large current density in the ion source, a higher voltage would be desirable. Research workers have suggested several designs of accelerate-decelerate systems that combine a high voltage across the ion source with a relatively low ion velocty at the exit of the thrust chamber. A design of this kind would probably lend itself favorably to an integrated system of high-yield ion source, efficient ion-optical collimation of the beam, and optimized exhaust velocity of the ions.

• **Power supply**—The unlimited supply of solar power continues to intrigue space vehicle designers. It has been proven that photo cells operate satisfactorily under space conditions. However, present efficiencies are of the order of 10 to 12% and manufacturing costs are high. While a multi-megawatt solar power supply is still too bulky and too expensive to be attractive as a power source for a large electric propulsion system, a solar supply for a system of a few kw appears promising.

As a source of heat power, the fission reactor seems to be superior to the bulkier solar mirror system. Even though nuclear reactors have not yet been operated in space, no excessive difficulties are expected. The reactor would be of the "fast" type with Na, NaK, Rb, He, or A as a working fluid, and with a simple shadow shield and probably a relatively large distance between the reactor and the rest of the vehicle. Heat exchange system, turbine, generator, cooler, and pumps or compressors should form a hermetically sealed unit to minimize the danger of leakages. The most severe problem is probably that of the high-speed bearings, which must operate unattended for a total period of 1 or 2 years under space conditions.

• **Electric generator**—The thermal energy from the prime power source may be transformed into electric power by a variety of methods. Turbogenerators, thermocouples, photocells and thermionic devices are the most promising conversion systems. A gaseous thermionic generator, using cesium

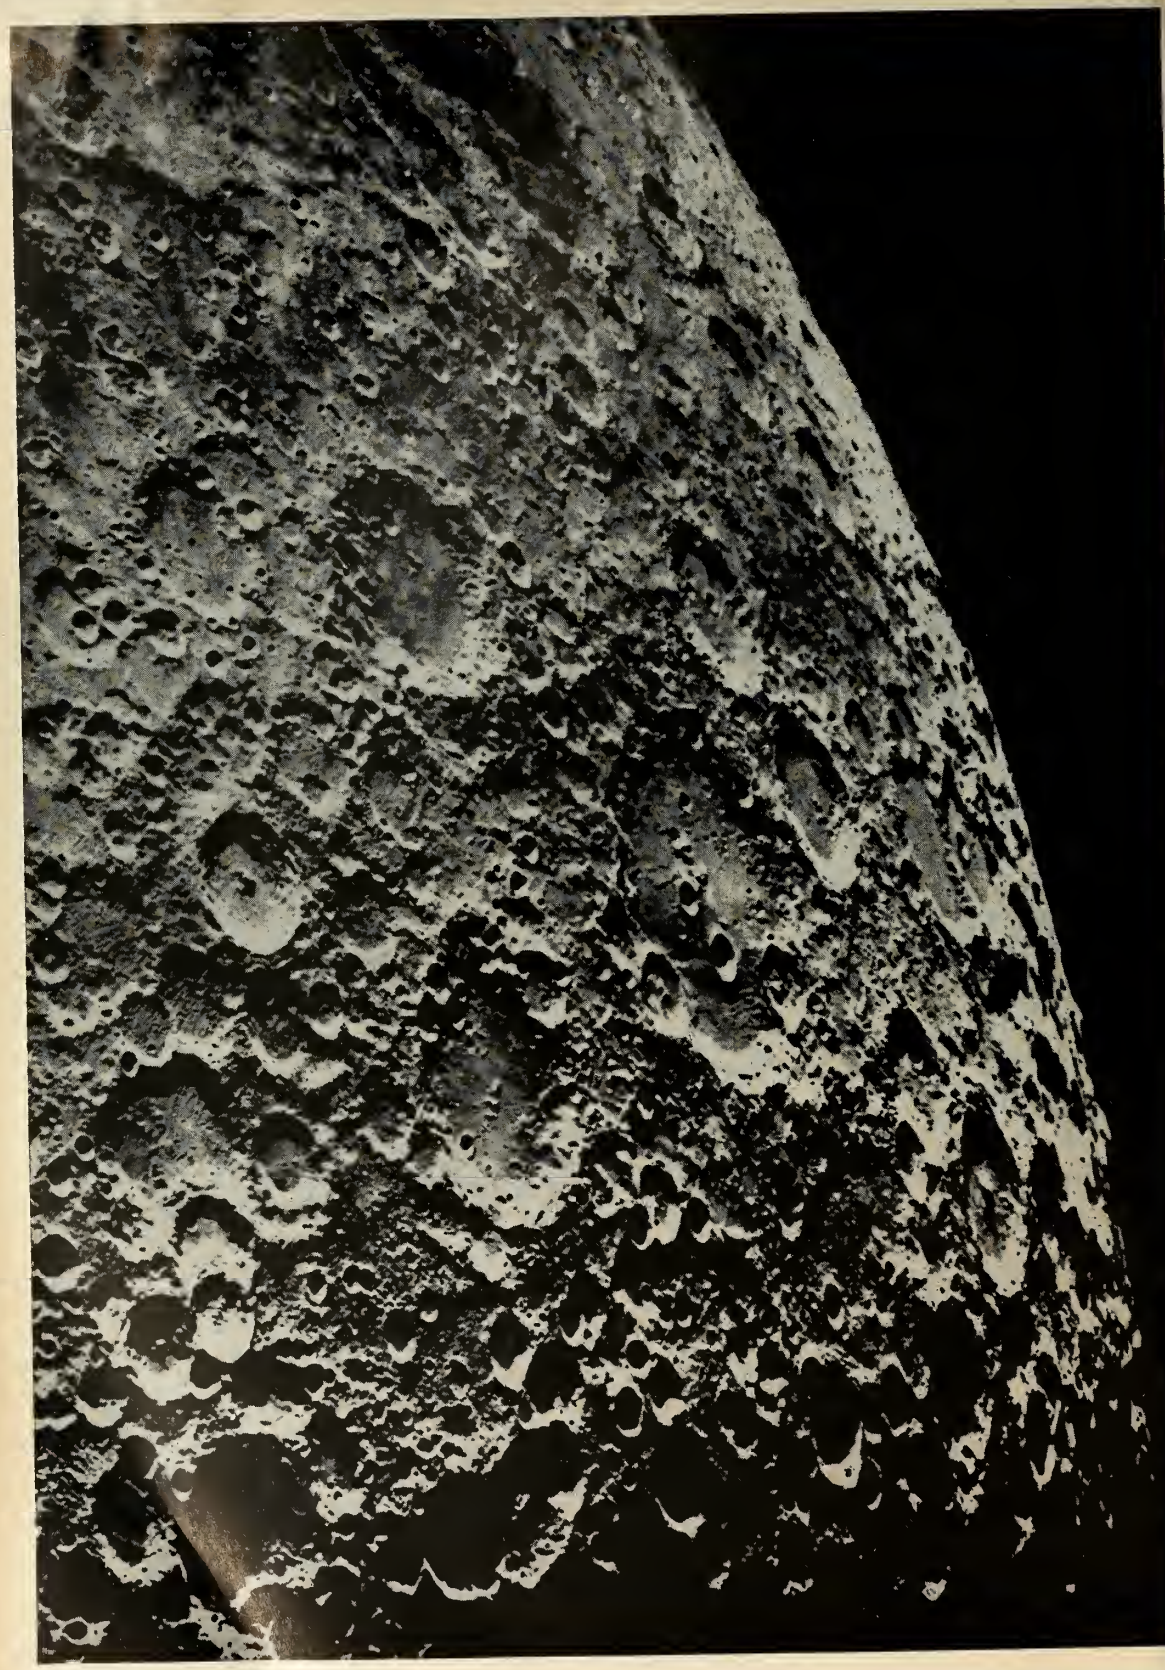
ANALYTICAL ENGINEERS

career opportunities with an expanding facility in New England . . .

Requirements: BS in Mechanical Engineering or AE degree, 2-5 years experience in one or more of the following: 1) small turbo-machinery (compressor, turbines, fans) 2) lightweight heat exchangers 3) thermodynamic cycle analysis 4) air conditioning, air and vapor cycle refrigeration.

Duties: Work includes both applied theoretical and experimental analysis starting with initial design and continuing through prototype. Involves performance computation defining configurations of components and complete systems to meet specifications. Opportunity to utilize IBM 704 and 705 for complex methods of analysis.

Join a technical group whose facilities and background knowledge are unrivalled in the industry. Your talents will be employed in the development of advanced concepts, and also in internal consulting work on problems encountered by the Design and Development Engineering Groups.



Very pleasant urban or suburban living conditions . . . opportunity for tuition-paid post graduate study . . . generous relocation allowance.

This Division of United Aircraft is now actively engaged in product diversification and development of jet aircraft equipment, ground support equipment and missile components.

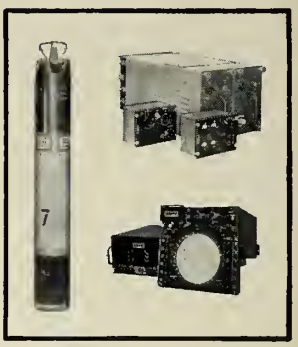
THE MILITARY REQUIREMENTS FOR MOON BASE

This is the title of one of four major space proposals developed by Martin for the military and astroscientific branches of our Government. The importance of this proposal is two-fold: the inevitability of an actual moon base program by this country within the next 5 years, and; the fact that we could and can undertake such a project now—not in theory but in "hard" engineering design. For Martin's eight divisions add up to one of the top capabilities in the free world for man's first ventures in space-planetary exploration.

MARTIN
BALTIMORE·DENVER·ORLANDO

vapor between hot and cold electrodes, should theoretically yield an efficiency of 30 to 40%, but no technically useful design is available as yet. Turbogenerators may be expected to provide an overall efficiency of 12 to 15% under space conditions.

From an engineering standpoint, turbogenerators are the best-understood power-conversion systems. The generator may be an electrostatic rather than an induction type machine; since electrostatic generators must provide surfaces as compared to induction type generators which must provide volumes, the electrostatic generator will be considerably lighter. It appears that a specific power of about 0.2 kw per kg may be feasible, referring to the entire powerplant including fission reactor, heat exchanger, turbine, generator, radiation cooler, and pumps.



• **Lunar ferry**—Besides interplanetary space ships of a few hundred tons weight, smaller space vehicles may use electric propulsion systems to good advantage. An unmanned lunar ferry could carry 50 tons of droppable payload at a total initial weight of about 85 tons; it would cover the distance from a 300-mile earth satellite orbit to the moon in about 3 months, and the return trip in one month. The ferry could make a number of round trips before exhaustion of the nuclear power supply. The only mass to be reloaded, besides the payload, would be the relatively small amount of propellant needed for one round trip.

A small electric propulsion system of a few kw of solar power and a thrust of half an ounce might be very useful as a corrective system for satellites which must achieve orbital parameters of high precision, such as 24-hour satellites. The total velocity change to be accomplished over a period of weeks and even months would not be more than a few hundred meters per second. The thrust units could be applied to produce changes of the longitudinal, lateral, or radial velocity vectors, of the orbital plane, of the ellipticity, or of the attitude of the satellite. When the desired velocity or direction change is accomplished, the electric power will be used for communications, TV observations, or measurements.

If the transfer time is not at a premium, an unmanned heavy satellite can be transferred from a low orbit to a high orbit with an electric system. With transfer times of a few months, satellites of hundreds of tons can be spiralled into high-altitude orbits with propulsion systems that weigh, including propellant, only a small fraction of the total weight. After arrival in the new orbit, the electric power will be available for other purposes.

AN ASW SYSTEM... DISPLAY/AIRBORNE RECEIVER/SONOBUOYS

Anti-submarine warfare equipment designed, developed and produced by *The Magnavox Company*, in conjunction with the Navy Department, provides patrol aircraft with eyes that see underwater by day and by night. The AN/ASA-16 Display System, together with SONOBUOYS, AN/ARR-26 Receiver systems and other associated equipment provide aircraft with a clear picture of the ocean-depths below them. They are part of the continuing contributions of *The Magnavox Company* in aiding the U.S. Navy to combat the growing submarine menace.

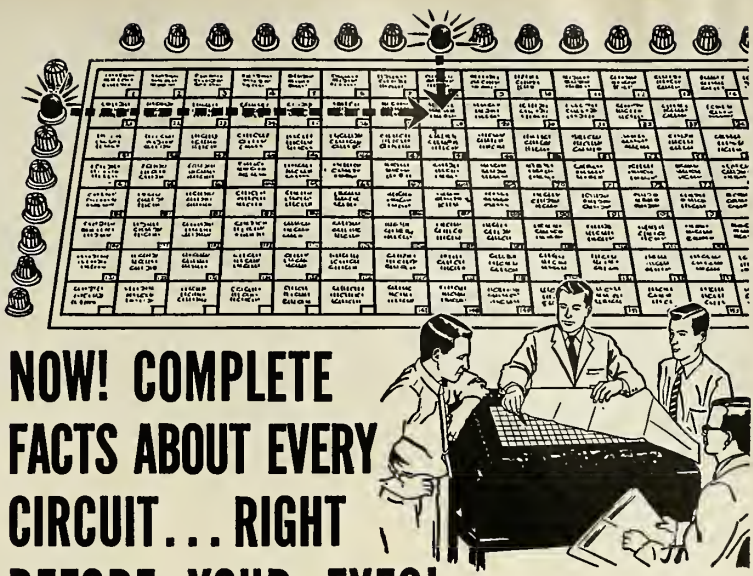
Convair Has 'Advanced' *Terrier* in Production

POMONA, CALIF.—An advanced version of the *Terrier* surface-to-air guided missile is in production at **Convair (Pomona) Division** of **General Dynamics Corporation.**

The weapon—according to Convair—has vastly improved performance compared with the original *Terrier*, which has been operational with the Navy since January, 1956.

Under present shipbuilding programs, the advanced *Terrier* missile will become a major element in the Navy missile arsenal. The USS Dewey, a guided missile frigate to be commissioned late this year, will be the first ship to be armed with the advanced *Terrier*.



The nuclear-powered aircraft carrier USS Enterprise, as well as two conventional carriers, three guided missile cruisers and 18 more guided missile frigates also will be equipped with the new missile. Eventually the advanced *Terrier* also will be installed in the nuclear-powered guided missile cruiser Long Beach and the nuclear-powered guided missile frigate Bainbridge.

Like its predecessor, the advanced *Terrier* will be used from mobile ground launchers for the antiaircraft protection of U.S. Marine Corps detachments on land.

The advanced *Terrier* will be able to intercept any present-day supersonic bomber many miles from its intended target, Convair said. Like the original *Terrier*, the weapon is a supersonic missile powered by two stages of solid-fuel rockets. The first stage, a separate booster rocket, supplies high thrust for a short period to launch and accelerates the missile to supersonic velocity.

After the booster fuel is expended, the empty booster case falls away and the second-stage rocket ignites. The second stage is part of the missile proper and maintains the velocity required to match any evasive maneuver the target aircraft might take.

Guidance and control systems for the advanced *Terrier* were designed and are manufactured by Convair under the technical direction of the Applied Physics Laboratory of Johns Hopkins University, Silver Spring, Md. Propulsion work for the missile is done by **Allegany Ballistics Laboratory,** Cumberland, Md. The fuze was designed by the Naval Ordnance Laboratory, Corona, Calif., and the warhead by the Naval Ordnance Laboratory, White Oak, Md.

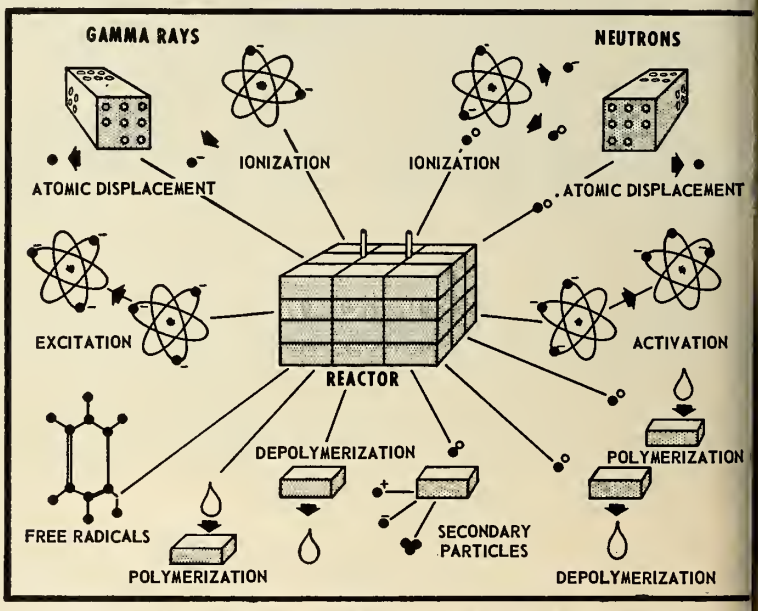
Heat Continues as Major Problem

Broad environmental criteria points up need for comprehensive materials R&D program. Here are the current research areas



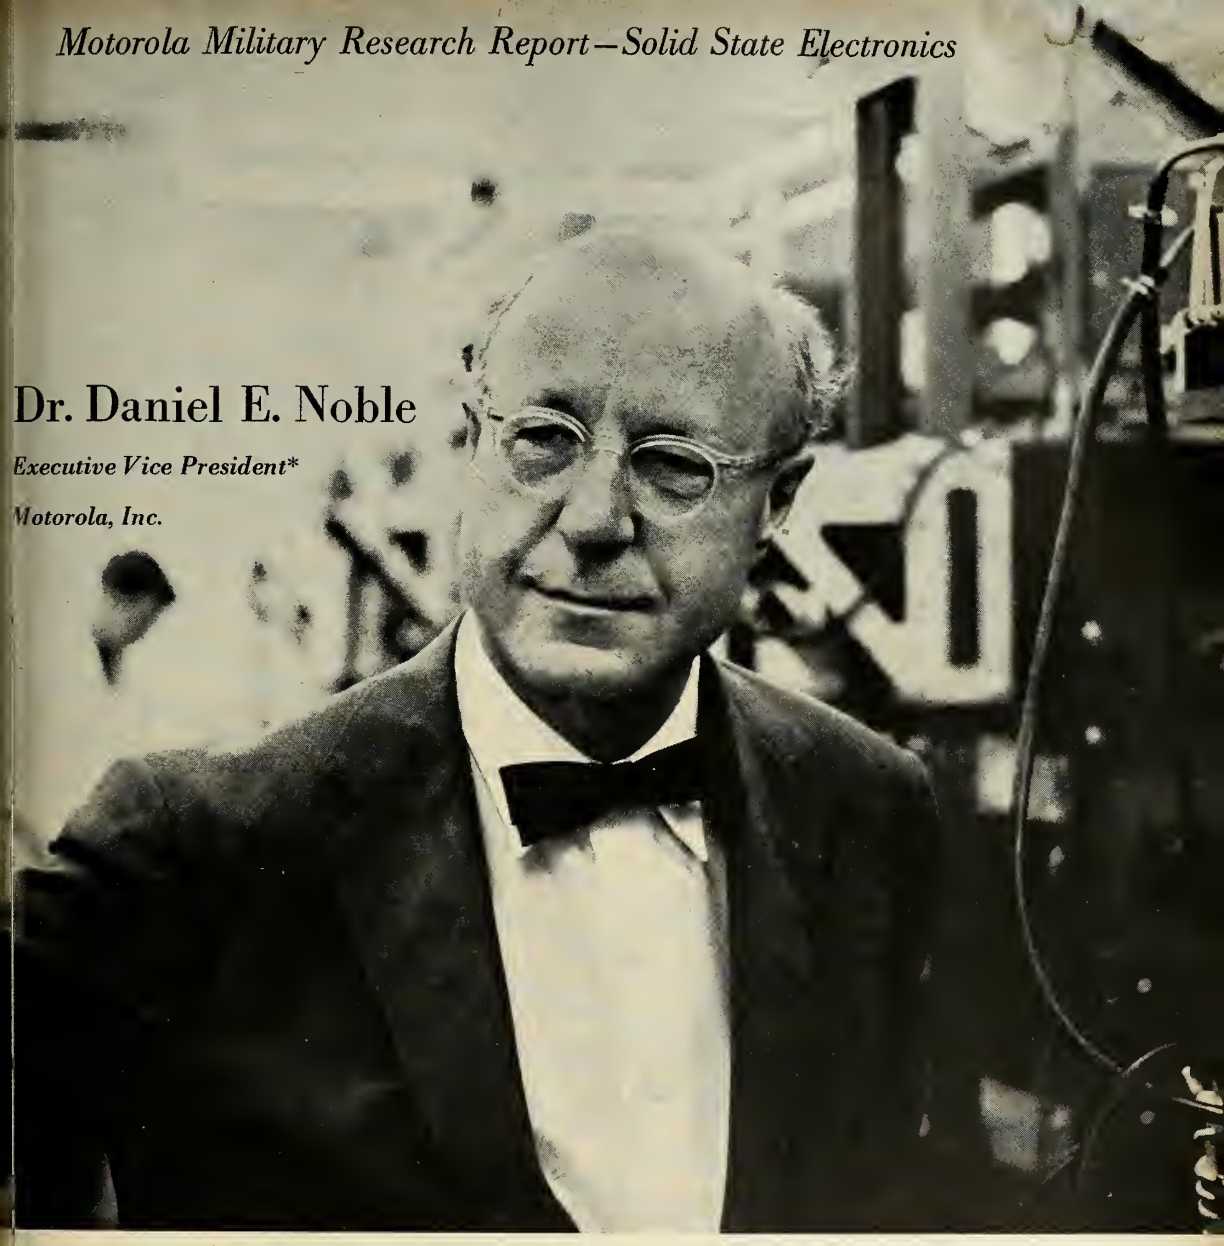
by
Lt. Col. Frederick C. Krug, USAF

WASHINGTON—The materials of which components of an aerospace vehicle are made and joined together are a common denominator basic to a successful weapon system.

Through the years, military departments have leaned heavily on civilian development of better materials from which new and improved equipment could be built. The need for such materials has increased rapidly during the past decade. We in the USAF have made known our requirements to the industrial and scientific communities. They have responded magnificently. One need only pick up and glance quickly through any recent trade or scientific journal to find hundreds of new materials announcements. To mention but a few at random—graphite cloth, energy conversion materials, extremely low thermal conductivity insulation, super-strength titanium alloys, ultra-high strength steels, very wide steel sheet, high-energy fuels, available rare metals with a wide range of properties, beryllium shapes, precipitation hardening stainless steels, sintered aluminum products, magnesium rare-earth alloys, flame-sprayed coating, ablation plastics; glass fibers with high modulus of elasticity and multi-directional magnetic steels. Yet in spite of such splendid advancements, materials problems continue to plague aeronautical vehicle designers.

• **Severe demands**—Contemplated weapon systems are placing these severe demands upon the basic materials of construction. These systems may be conveniently grouped into three broad classes:

a. Hypersonic Strategic Weapons
b. Ballistic Weapons
c. Satellite Weapons



SOME OF the reactions that occur when materials are exposed to gamma rays an fast neutrons. Generally, the result is increase in strength.

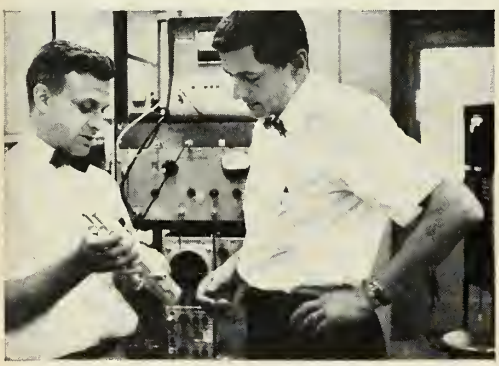
"In this new era, Solid State Electronics will spread its influence to every form of human endeavor and will contribute substantially to scientific achievement in all fields."

Dan Noble

PLEASE TURN PAGE



Ferrimagnetic principles are demonstrated by scien tist in charge of Motorola's Solid State progran Dr. H. William Welch, Jr., director of researcl and development, Military Electronics Divisior Dr. Welch as a University of Michigan professo established that school's Solid State laboratory an introduced new curricula in Solid State devices an their applications. He holds an I.R.E. Fellow Awar for contributions to development of solid state device and microwave tubes.

Typical of solid state materials now being offered sale by Motorola are these ferrite rods and bars be examined by Donald L. Fresh, manager of the So State Materials Laboratory.

John C. Cacheris, right, manager of the Microwave Applications Laboratory, and a member of his staff inspect a parametric amplifier, one of several devices now being produced by Motorola's Solid State Dept.

Imaginative leadership plus the most modern of laboratory facili have helped foster a creative environment that is attracting top tal to Motorola. Here, Dr. Arthur L. Aden, associate director of resea and development for Motorola's Military Electronics Division, sh a new member of his staff equipment for photographing printed cuits. Dr. Aden welcomes inquiries from qualified engineers and ph cists who would like to join his department.

James R. Black, manager of Motorola Microelectronics Laboratory, heads work which leads toward the mass production of economical microelectronic components so small that several would fit on the period that ends this sentence.

How Solid State Electronics is shaping the future

MILITARY ELECTRONICS—industry as well—is being radically changed by rapid advances in solid state technology. Predicted for the near future are computers small enough to fit in the palm of a hand, receivers that will detect the weakest signals from distant satellites.

Motorola's highly experienced Solid State Department, in close cooperation with the Semiconductor Products Division, is advancing the state of the art on several fronts, one of the most promising of which is microelectronics.

By making use of crystalline functional circuit elements created in volume quantities by surface etching or film deposition methods, Motorola researchers anticipate they will soon be able to design equipment with component densities of tens of millions per cubic foot.

This high density will result in a great reduction in systems and computer size coupled with a significant increase in reliability, and it will lead to the development of self organizing computers for such complex tasks as the solution of military logistics problems and space guidance.

In microelectronics and in other areas, Motorola scientists, including those of the Semiconductor Division, are investigating the ferroelectrical, ferrimagnetic, piezoelectrical and pyroelectrical characteristics of monocrystalline and polycrystalline solids. New materials possessing these useful characteristics are created and produced in the Materials Laboratory. Typical applications: newly developed ferroelectrical or piezoelectrical materials to be used in transducers for submarine detection.

At present, the Applications Laboratory is making extensive use of ferrites and semiconductors in the development of broad lines of isolators, circulators and parametric amplifiers. The latter device has already demonstrated its worth in satellite-tracking radars, IGY research receivers, uhf television receivers and radio. In the study and design stage are new and advanced ferrimagnetic devices such as microwave switches, ferrimagnetic limiters and semiconductor switches.

Still another research frontier where striking preliminary results have been achieved is a low-voltage facsimile paper for the transmission of teletype and other information. Applications in the fields of combat surveillance, logistics control and other important military programs are foreseen.

Military Electronics Division's expanding capability in solid state electronics is described in a new booklet entitled: "Solid State Frontiers at Motorola." *Request your copy from Technical Data Service, Motorola, Inc., Military Electronics Division, 8201 East McDowell Road, Scottsdale, Arizona.*

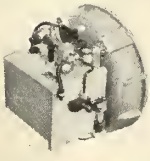
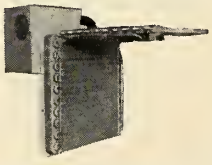
TEMPERATURE CONTROL EXPERIENCE

REFRIGERATION COOLING



Sensitive aircraft and missile components and systems often require temperature control within close limits — while ambient temperatures fluctuate widely. Eastern refrigeration-type cooling systems are ideal for such conditions.



Designed for the strictest military requirements, these vapor-cycle closed-system packages are built around a highly efficient compressor powered by a special 400-cycle motor. Unique condensing and special cooling methods are called upon to meet the most unusual operating requirements, the most demanding specifications.

Capacities range from 100 to 6000 watts; operating altitudes extend to 100,000 feet. Some units, of the "boil-off" type, perform almost without regard for extremes in altitude and temperature.

Call on Eastern for imaginative solutions to *all* avionic cooling problems . . . and write for new Bulletin 360.

As indicated, heat continues as the major environmental problem. High speed re-entry of ballistic and satellite vehicles will require materials capable of retaining structural integrity under heat fluxes of thousands of BTU/sq ft-sec. for possibly several minutes duration. Moderately stressed structures and propulsion systems employed in satellites will require materials whose properties must remain stable for many thousands of hours.

These broad environmental criteria point up the direction for a comprehensive materials research and development program. In addition to the operational high-temperature and long-life requirements, these problem areas include weight reduction, operation within a nuclear and cosmic environment, fatigue, reliability, and availability.

Speaking at the October, 1958, Joint Army-Navy-Air Force Conference on Elastomer R&D, J. R. Townsend, Special Assistant to the Department of Defense Director for Research and Engineering, stated:

"The persistent unreliability of some of our missile systems points to the dearth of materials with good properties in these extreme environments . . . To build reliability into these systems we must develop better materials in the laboratory, convert the laboratory product into a material of controlled properties capable of being shaped, and then design and manufacture the components to exploit fully the advanced properties of the new material."

In addition to the examples cited by Townsend, we can add such immediate problems as the short life of rocket nozzles, the failure of thin-shelled rocket cases, the incompatibility of seals and hoses with various high-energy fuels, and the exorbitant weight

About the Author

Lt. Col. Frederick C. Krug is chief of the Metals and Ceramics Section, Materials Branch, Air Research and Development Command at Washington, D.C. A graduate of Pennsylvania State College, he has been an Air Force officer since 1943.

He has been a weather officer, a liaison officer and, since 1950, a specialist in metallurgy. He has been an Air Force member of the DOD Critical Materials Conservation Committee and the NACA subcommittee on Aircraft Structural Materials. Lt. Col. Krug has headed the Metals and Ceramics Section since 1955.

of nuclear shielding materials.

Therefore, the prime objective of the Air Research and Development Command's applied research program in materials is to provide the leadership necessary to extend significantly the useful range of application of aeronautical materials. The program includes metals, plastics and other synthetics, coatings and coating techniques, and unique methods for developing new materials.

• **Refractory metals**—New metallic materials are required to meet the needs of rocket and hypersonic airframe designers. This is primarily because of severe temperature extremes extending from below –400°F to over 5000°F. The super-alloys composed of such elements as nickel and cobalt give satisfactory long-time service (hours) to near 1700°F; but at temperatures over 2000°F, only several minutes of useful life can be expected. A class of metals known as the *refractory metals* holds potential for greatly extending this temperature limitation.

Four of these refractory metals are shown in Figure 1. Nickel, cobalt, and iron are included for comparative purposes. All have melting points exceeding 4400°F. The potential useful temperature of these metals has been estimated and is shown in the last column. Unfortunately, these refractory metals are subject to severe oxidation at elevated temperature and are brittle. Much research is needed to overcome these problems.

• **Coating techniques**—One approach to the oxidation problem of refractory metals is through the use of protective coatings, which must be impervious, resistant to thermal shock, and capable of withstanding a highly corrosive and erosive environment. The technique of applying such coatings is highly significant since uniformity and adhesion are particularly important.

The flame spray technique, which uses an arc plasma jet, is considered by many to be an outstanding metallurgical achievement of 1958. The temperature generated by an arc jet is so intense (15,000°F) that it can vaporize all known materials. Selected materials can thus be condensed as a coating on the component requiring protection. The potential of this arc plasma jet coating technique has yet to be fully exploited. With further development, for example, protection of nose cones and hypersonic leading edges may be greatly facilitated.

A direct development from the Air Force's program has been the "troweled" coating technique. By this procedure, heat-insulating coatings are laid up by hand-troweling of the ceramic material over a steel wire reinforcement.

Callery opens office in Los Angeles—Fuel and propellant users on the West Coast can now contact Dr. Robert G. Brault, Callery's Manager, Western District, for helpful technical service. He has opened an office at 3141 Century Boulevard, Inglewood, California. Telephone: ORegon 8-9382. Dr. Brault was formerly Research Coordinator of the Project Zip high-energy fuel program at Callery's R & D Laboratories.

Diborane as fuel for rockets, ramjets, and turbojets—With a heat of combustion of 31,300 Btu/lb. and extremely good combustion properties, Diborane is an attractive fuel for air-breathing engines. Diborane, a gas at standard conditions, can easily be liquified (boiling point –134°F). With modern insulating methods, it should be storable for long periods. Its specific gravity at a temperature slightly above its melting point (–265°F) is 0.56, so that it contains more Btu/gallon than JP fuels. Diborane has excellent heat-sink capabilities.

Recent calculations, based on the most recent thermodynamic data, show Diborane-LOX to have an I_{sp} of 349 sec. (1000/14.7 psia, shifting equilibrium). With its higher density and boiling point, it may be superior to hydrogen for some applications. Diborane will soon be available in tonnage quantities. Write for Technical Bulletin C-020 for detailed information.

HiCal® fuel now available—Since Callery's production of HiCal, high-energy fuel, will exceed immediate military test-program requirements for the next few months, substantial quantities of HiCal-3 are now available for authorized users with suitable security clearance. If you have been waiting to test HiCal-3 in engines or components, write now for specific information. Our HiCal-3 Handling Bulletin C-1100 is available on request.

New specific-impulse calculations—Specific-impulse data for several combinations of boron-containing fuels with various oxidizers have recently been calculated and tabulated. Most of these data are confidential, but Callery representatives would be pleased to discuss them with you on a classified basis.

Fire-fighting films on HiCal and pyrophoric fuels—The HiCal film shows the relative ease and safety with which a stable mechanical-foam blanket can extinguish burning HiCal fuels. Another 15-minute film illustrates the techniques available for combating fires of Trialkyl Boranes.

For information or loan of films, write to Defense Products Dept., Callery Chemical Company, 9600 Perry Highway, Pittsburgh 37, Pa.

The Air Research and Development Command is very much interested in coating development for oxidation and erosion protection of the refractory metals and graphites up to and beyond 5000°F.

• **Thermal protection**—As mentioned earlier, the Air Force has requirements for both long- and short-time thermal protection techniques. An example of the long-time requirement is the leading edge of a hypersonic system such as a boost glide vehicle. The short-time requirement is represented by ballistic nose cone and satellite re-entry. The refractory alloys hold promise for satisfying the leading edge and hot-spot structural problems of boost glide systems. However, much development combined with application studies are needed. Oxidation protection coatings will be required and a high degree of thermal shock resistance will be needed in the refractory bodies. At the present time, the potentially useful materials all appear to have limitations. These include low strength above 2500°F, lack of protective coating development, and lack of fabrication experience. Much work is required to overcome these deficiencies.

Designers and developers of nose cones for high-speed re-entry of the earth's atmosphere have been faced with one of this decade's most challenging technical problems. Obviously some sort of a protective shield is required. Fundamental to a solution is complete thermophysical materials property data. Lack of such data continues as one of the major limitations to design and development of Air Force weapons.

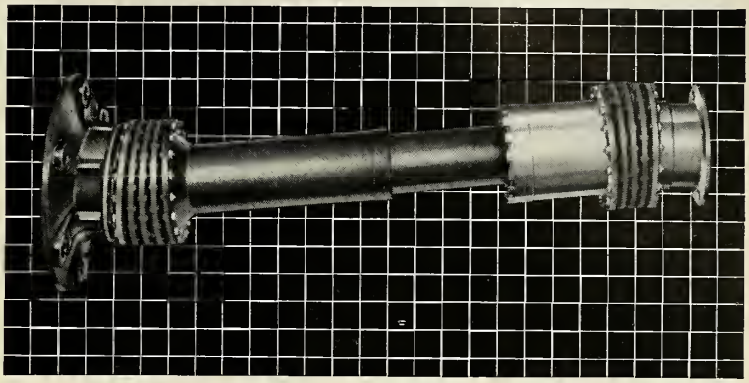
Based on the data available, several thermal systems show promise for applications in such an extreme heat flux environment; for example, systems based on the heat sink or ablation characteristics of materials. Comparatively, ablative materials consume up to 20 times as much heat per pound of material as can be absorbed by heat sink materials. An ablating system is depicted in Figure 2. As the material is exposed to progressively higher temperatures, large quantities of heat are consumed in the phase transformations that take place.

• **Beryllium materials**—Beryllium has many outstanding properties that make it an exceedingly attractive air weapon material. The element with atomic number 4, it is lighter than aluminum yet stiffer than steel. It is one of the best heat sink materials known. One of the most promising applications for beryllium is in guidance systems, which require a very light and strong material, dimensionally stable over a wide temperature range. Beryllium has provided the answer at a significant increase in

performance as well as weight savings over its steel predecessor.

As an example of weight savings, a 13-lb. beryllium nose cone has the same heat sink capability as a copper cone weighing nearly 100 lb. Beryllium, or some beryllium compounds, offer potential as leading edge material for weapons exposed to severe aerodynamic heating.

Why, then, hasn't this potential of beryllium been exploited? The metal has been avoided because of its brittleness, scarcity, cost and toxicity. Adequate and effective techniques for joining (welding, brazing, etc.) have also been lacking. The Air Force is currently sponsoring development of beryllium alloys and fabrication techniques. With successful development of a ductile beryllium alloy or composite, a superior material will be available for many specialized applications. Furthermore, because of this metal's exceptional strength-to-weight ratio, it should find application in satellite and space weapons in which weight savings are vital.



• **Plastic materials**—Plastics have solved many Air Force problems. Their substitution for glass in aircraft gave significant weight savings; they contributed outstandingly to airborne radar. These uses are dwarfed by the potential of plastics in future weapons.

Plastics are practical as nose-cone material because of their outstanding ablation characteristics. In a simulated re-entry environment such as rocket blast or the plasma arc, reinforced plastic materials have shown superior performance to ceramics and high-temperature metals. While the original polyester plastics were limited to structural applications below 200°F, the development of heat-resistant silicone and phenolic resins has extended the maximum long-time operating temperature to 700-800°F. This temperature capability combined with the excellent strength-to-weight properties of plastics have provided the weapon designer with a highly versatile structural material from which rocket chambers, pressure vessels, and sandwich structures can be built.

Future Air Force weapons will need plastics with significantly extended strength and temperature ranges. For example, for rocket thrust chambers the present strength-to-weight ratio of reinforced plastics should be doubled.

• **Emissivity coatings**—Many Air Force weapons of the future will not enjoy the natural protection of the earth's atmosphere and will be exposed to the total radiant energy of the sun. Temperature control of such vehicles will be highly dependent upon the materials of construction. The balance reached between absorbed solar energy

BENDIX FLEXIBLE POWER DRIVE SHAFT SOLVES MISALIGNMENT PROBLEM

POSSIBLE IN-USE DEFLECTION of a *Model 19E29-3 Flexible Drive Shaft. This standard 20-inch-long unit weighs 12 pounds, is rated 42.5 h.p. at 2800 RPM to 11,000 RPM, and includes a torque limiting clutch.*

Transmission of power to accessories mounted remotely from aircraft engines is no problem when one of Bendix Utica's flexible drive shafts is used.

High speeds are possible . . . because of symmetrical shaft design. Two constant velocity ratio flexible joints, made up of high alloy steel diaphragms, permit up to plus or minus 10° intermittent deflection and plus or minus 5° continuous deflection while maintaining rotational balance in the shaft at any speed.

High operating temperatures won't affect efficiency of a Bendix Utica shaft. Unique joint design permits continual operation at maximum speed, at any temperature up to 600° F.

No lubrication is required for flexible torque carrying members. The flexing diaphragms transmit load, with no rubbing or sliding surfaces. They generate no frictional wear and little heat, resulting in long shaft service life.

We can solve virtually any power take-off problem using one of our standard or special design flexible shafts. Special designs can be engineered for unusual applications involving almost any degree of misalignment and power speed requirements.

A mechanical disconnect can be provided integral with the shaft to disconnect driven accessories from the driving source.

No matter what your aircraft power transmission problem, you'll get the best answer to it from Bendix Utica.

100 CPS X-Y RECORDING

with immediate readout

THE NEW SANBORN MODEL 670 OPTICAL X-Y RECORDER HAS

- 1% linearity
- frequency response 3 db down at 130 cps independent of amplitude
- writing speeds to 2500 in/sec.
- 8" x 8" direct print paper chart
- trace monitoring on phosphorescent screen

X-Y RECORDING never before possible with electro-mechanical instruments can now be done with the new Sanborn Model 670 X-Y Recorder. Direct writing on ultraviolet-sensitive recording paper by a beam deflected by optical galvanometers makes possible the combination of fast writing speed and 130 cps frequency response not found in any other X-Y recorder. Transistor characteristics, acceleration and vibration of mechanical parts and events of similar short duration can be recorded with linearity of *1% of full-scale* and at trace speeds as fast as *2500 inches per second*. Square wave response exhibits no greater than ½% overshoot *at any amplitude;* sensitivities as high as 62.5 uv/inch (depending on preamplifier used).

PLOTS OCCUPY AN 8" x 8" RECORDING AREA and can be previewed or monitored on the instrument's phosphorescent screen. An Axis Record switch to print X and Y axes on the record, and a Beam Intensity Control to assure maximum trace clarity, are among the front panel controls provided. An 8" x 8" sheet of the ultraviolet-sensitive chart paper (stored in drawer at base of cabinet) is easily placed on the back of the hinged screen. Brief post exposure in normal room light is the only developing process.

OPTIONAL INTERCHANGEABLE PREAMPLIFIERS for each axis presently include the Model 850-1300B DC Coupling and Model 850-1200 Phase Sensitive Demodulator; a Carrier Preamplifier, High Gain Preamplifier and a time base generator are now in development. Driver Amplifiers are compact, fully transistorized plug-in units with single-ended input and output. Galvanometers are low resistance, low voltage units of rugged, enclosed construction; sensitivity and damping are independent of coil temperature. Accessible, unitized circuitry also extends to the power supplies—a front-panel plug-in for both preamplifiers and a second supply for both driver amplifiers. A built-in blower provides constant, forced filtered air cooling. The Recorder can be rack mounted in 15¾" of panel space, or housed in its own 20" x 20" x 21¼" optional portable cabinet.

Ask your local Sanborn Soles-Engineering Representative for complete information on the Model 670 X-Y Recorder, or write the Industrial Division in Waltham, Mass.

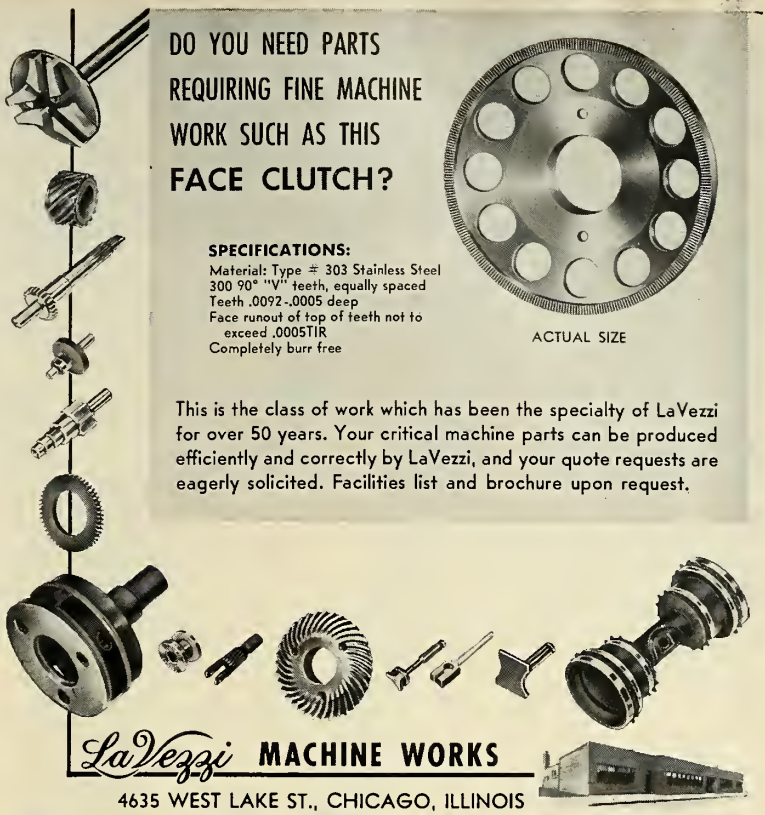
INDUSTRIAL DIVISION

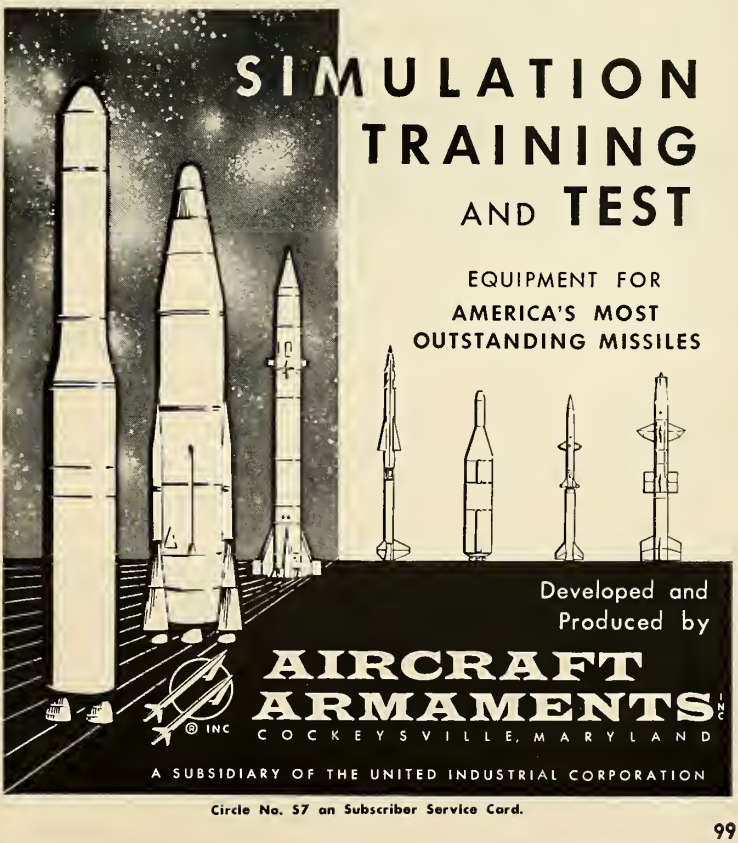
175 WYMAN STREET, WALTHAM 54, MASS.

and re-emitted infrared radiation will determine the skin temperature. It should be noted that the materials' properties of emissivity, absorptivity, and reflectivity are vitally important to the heat balance. To illustrate, consider the following: Metals are normally excellent reflectors, but poor emitters, of long wave length radiation (infrared), while paints are generally poor reflectors but good infrared emitters.

What this boils down to—and has been verified by actual measurement—is that the equilibrium skin temperature of painted surfaces will be much lower than polished metal surfaces. Although such coatings may provide excellent thermal balance, they will make infrared detection correspondingly easier. Therefore, an optimum coating is needed which protects the vehicle thermally and also from infrared or radar detection.



Although it appears that careful selection of coating material can provide good temperature control, several other considerations introduce an element of caution into such a conclusion. First, these temperature calculations ignore internal heat; and, second, abrasion or other surface attack may drastically alter the material properties of emissivity, absorptivity, and reflectivity.



• **Tailoring materials**—Gone are the days when the empirical approach of "cut and try" could be relied on to yield improved materials. Furthermore, the inherent qualities of natural materials such as rubbers and greases are inadequate for advanced weapon designs. Therefore, the trend to synthetically tailored materials has been greatly accelerated. The Air Force's materials program has pioneered in molecular engineering through its plastics and elastomeric (synthetic rubber) applied research efforts.

The fluorinated silicones were tailored for heat-resistant applications. Even these materials, however, have only modest temperature capability with limited nuclear radiation and high-energy fuel resistance. As an approach to significant improvement, materials engineers are attempting to tailor (polymerize) rubber-like materials that employ a metallic constituent, such as tin or boron.

Another urgent Air Force objective is compatibility of seals, gasket, and hose materials with high-energy fuels. Hydrazine, for example, seriously degrades many of the best available elastomers. Applied research is therefore being directed toward tailoring elastomeric materials that will be compatible with new propellants.

• **Radiation damage**—Engineering materials for future Air Force weapons must be capable of survival in a nuclear environment, not only where

Here is a man you should know
he's a DELAVAN FUEL INJECTOR SPECIALIST

His name is Roger W. Tate. He did his doctoral research in the field of pressure atomization at the University of Wisconsin, has taught reaction kinetics, and worked on process improvements for petroleum refining.

Dr. Tate is Director of Research at Delavan. He has developed many atomizing devices and uniquely accurate test equipment for Delavan. He is widely known for his research on spray analysis and fuel injection.

Specialized talent like Dr. Tate's is the main reason for Delavan's leadership in fuel injection. If fluid metering and atomization are part of your product, take advantage of Delavan's specialized experience and ability to deliver aircraft quality. Send specifications to the address below for free recommendations.

nuclear power plants may be employe but also where exposure to cosmic o Van Allen radiation is anticipated. I radiation studies of components, suc as radio receivers, motors, capacitor have shown that resultant damage is direct function of the resistance of th materials of construction.

Gamma rays and fast neutrons ar the prime triggers of radiation effect in materials. The illustration on pag 90 shows some reactions when ma terials are exposed to these radiation Atomic displacement and ionization oc cur in metals. Generally, the result i an increase in strength and hardnes but a decrease in ductility. This is nc considered serious. The exception t this conclusion is in solid-state device made of the semi-conductor element such as germanium. In such device even slight atomic disturbances can not be tolerated.

Nuclear radiation can drasticall alter non-crystalline materials such a rubbers, lubricants and adhesives. Th chemical bonds between atoms of thes materials are quickly destroyed o changed. Greases may turn to gum adhesives and rubbers may harden an crumble. In such cases, the radiation i actually polymerizing or depolymeriz ing the materials. Therefore, supe imposed upon the Air Force's require ment for much improved thermal, co rosion, and erosion resistant material is significantly improved nuclear radi ation resistance.

Although additives (anti-rad) rais somewhat the radiation tolerances o some lubricants and polymers, this ap proach does not appear to offer signifi cant advancements. We must develo materials that are intrinsically stable t nuclear radiation. It was proven i 1958 that polyphenol ethers for or ganic fluids are many times superio to those lubricants containing addi tives. Concurrent with these develop ment efforts, we must continue a extensive testing program to study an evaluate the effects of a nuclear en vironment on all classes of air an space vehicle materials.

This has been a very brief look a the requirements, scope and directio of the Air Force's materials program At the 1958 ARDC Materials Sym posium, Maj. Gen. Marvin C. Demle now Director of Research and Deve opment, Hq USAF, stated, ". . . . ma terials research and development, stim ulated by the free thinking and creativ imagination which only a democrati society such as ours encourages, wi contribute significantly to Air Forc weapon supremacy." The resulting ma terials can significantly raise the lim itations now imposed by weight, ex tremes of heat, corrosive and erosiv environment and nuclear radiation.

on the countdown
split-second communication for split-second *action*

Launching today's highly complex missiles demands an unprecedented degree of "team" cooperation. Hundreds of scientists, technicians and specialists must be kept constantly informed during the all-important countdown. Instant action-getting voice communications is the best answer.

An urgent call for a key man . . . an important change in fueling requirements . . . a broken control cable—all require *and get* instant action over a DuKane "job-engineered" communications system. DuKane systems are today providing these vital functions at Patrick Air Force Base, Fort Churchill, and White Sands.

DuKane's advanced engineering group, backed by more than 36 years of specialized experience in the communications field, is available to help you plan your system. Their experience is your guarantee of the best in communications.

For any missile base ground communications need, write or wire DuKane Corporation, Department MR-5, St. Charles, Illinois.

And, if you specify electronic equipment, ask for DuKane's Electronic Equipment Symbols wall chart . . . no obligation of course. DuKane products are installed and serviced by a nationwide organization of factory-trained experts.

R/M PYROTEX® REINFORCED PLASTICS ... DEVELOPED TO ENDURE THE FIERY REALM OF THE ROCKET

Light, strong, heat resistant . . . for low-cost, precision fabricated rocket parts— both structural and aerodynamic

High heat resistance makes R/M Pyrotex the ideal materiel for rocket sliver traps, igniter tubes, and tube covers. Pyrotex parts exhibit high strength retention after repeated exposure to 5000-6000° F.

Looking for a material that will withstand the elevated temperatures generated by missiles and rockets—internally from burning propellants, externally from aerodynamic heating? Must this material have good insulation and thermal properties, chemical and water resistance, and take a smooth finish? If so, one of R/M's family of Pyrotex reinforced plastics may be the solution to your problem.

The many outstanding thermal and structural features of R/M Pyrotex have led to its use on almost every U.S. missile. It has been fabricated into parts such as nose cones, fins, igniter tubes, rocket throats and sliver traps. Its exceptionally good dimensional stability makes possible mass production to precision standards. And it is low in cost. Write for additional information.

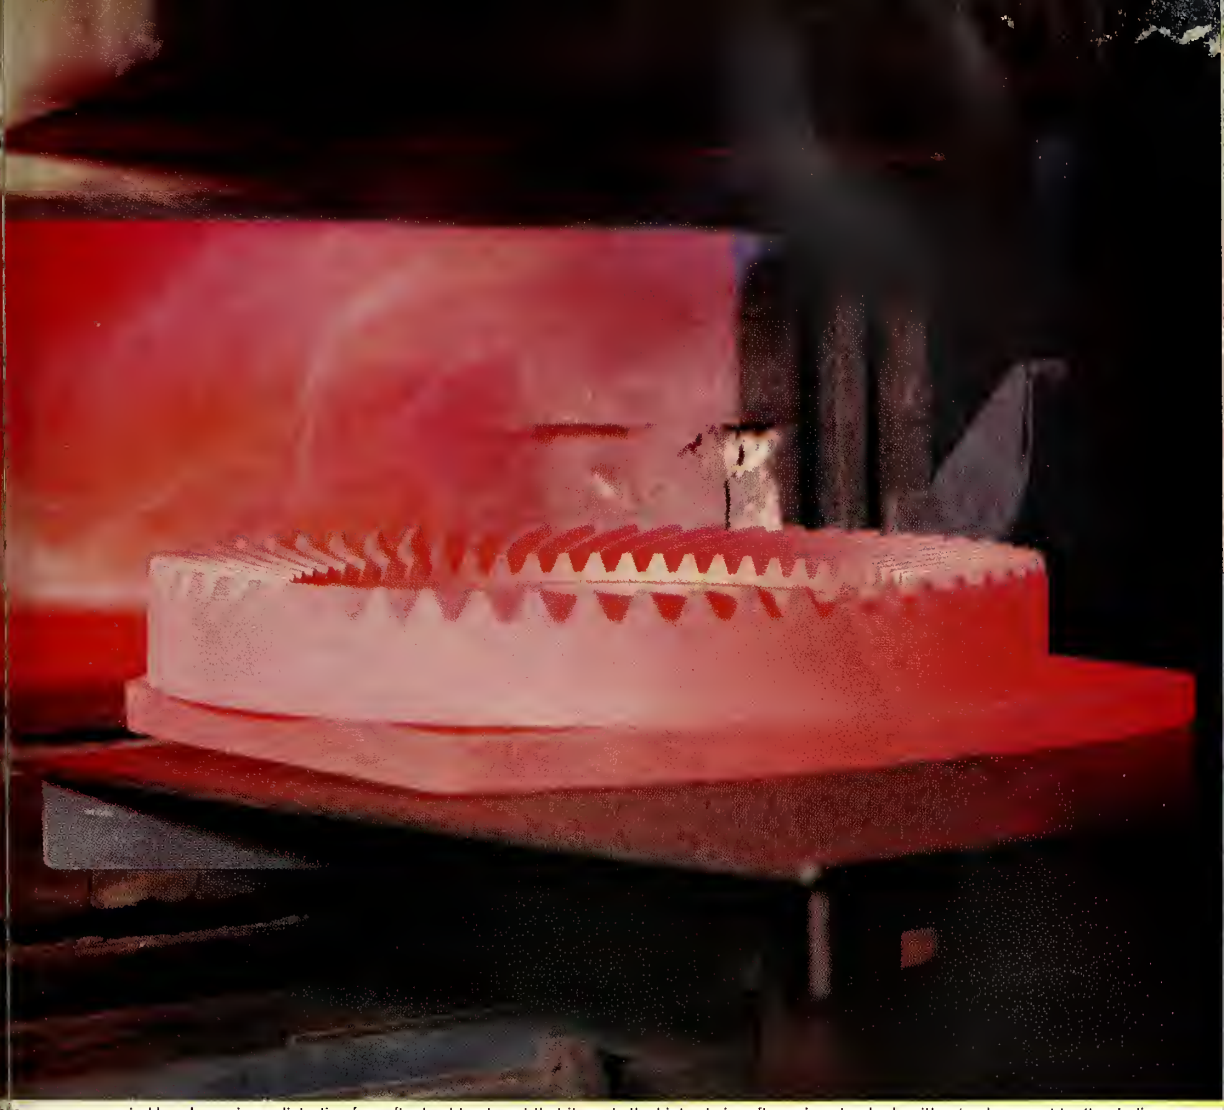
Sperry Duplicates FBM Sub Navigational Control

SYOSSET, L.I., N.Y.—An exac replica of a *Polaris* missile launchin submarine's navigational control cente has been put into laboratory operatio by **Sperry Gyroscope Co.**

For the first time, navigational in struments that will guide all Nav *Polaris* submarines are being system tested in a control center identical t that aboard a submarine.

Officially called the "Ashore *Polari* Navigation Center," it is more com monly referred to as the "Navigatio Island" by Sperry engineers. It is th nucleus of a test, integration an evaluation program assigned Sperry b the Navy, to assure performance fro this equipment before it takes to th open sea, under a schedule to hav *Polaris* operational by 1960.

The ashore test program is house in Sperry's new 52,000-square-foo Syosset, L.I., **Marine Division** plan which supplements existing productio facilities. Mission of this laboratory center is to solve the assembly an operating problems of a combine complement of advanced navigation equipment.



Sperry has had the responsibilit for developing inertial and other na igation systems since the beginning o the *Polaris* program, together with th responsibility for integrating all of th seagoing navigation systems. The te program is now operating for the fir year of a three-year period under $1,570,000 contract.

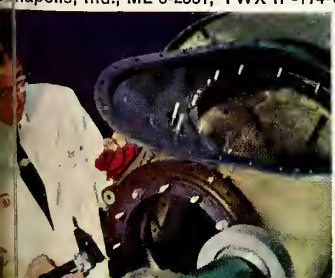
Among the major instruments an systems to be tested in the Ashor *Polaris* Navigation Center are NAVDAC (The Navigation Data A simulation Center, a master computer SINS (the Ship's Inertial Navigatio System), the Type 11 Stabilized Per scope System (permitting celestial na igation while submerged) and othe classified systems.

The dimensions, shape and cablin of the sub's navigation control cent have been reproduced exactly in th ashore test facility. The simulated hu section is a duplicate of the sub's na igation center.

Although much of this equipme has been used on other ships (i.e inertial navigators and NAVDA aboard Navy's test ships Observatio Island and Compass Island) this wi be the first time that all of the instr ments will be working in concert a a complete system in the confined are available on a submarine.

Sperry will develop casualty co trol procedures for emergency oper tion in the event of an injury to perso nel or damage to equipment.

arge concave spiral bevel gear is so distortion free after heat treatment that it meets the highest aircraft gearing standards without subsequent tooth grinding.



Precision is our only product!

In the rapidly changing field of aeronautical technology, the word "precision" becomes more and more common in use. At Indiana Gear, however, precision has always been more than a word. It is a way of thinking . . . a method of working always beyond the fringe of the state of the art.

The man:

...a U.S. airman-engineer—carefully selected through rigorous test procedures from Military personnel. He will have the combination of mental acuity, superb physical condition and emotional stability necessary for pioneering in space exploration.

The mission:

...satellite observatory—a vehicle arrangement similar to this could orbit a three-man astronomical crew for several weeks. Empty fuel tank is used for living quarters. Nose section serves as re-entry vehicle for return to earth. The astronomical telescope is gimbal-mounted. External equipment shown is mounted after orbit has been attained.

The means:

...Space projects are accelerated by research equipment like the Douglas high-altitude chamber at Tulsa, largest in the U.S. In it, space environment problems can be worked out under near-operational pressure conditions, shortening the time required for development.

Depend on **DOUGLAS**

The Nation's Partner in Space Research

Diborane Applications Sought by Callery

Callery Chemical is negotiating for use of part of the U.S. Sunflower Ordnance Works, Lawrence, Kan., to develop, test and produce new high-energy rocket propellants—among them diborane.

The company said the Sunflower works offers facilities for exploring possible applications of diborane, which has 2½ times the density impulse (with LOX) of liquid hydrogen. Liquid diborane is 5 to 6 times as dense as liquid hydrogen, with a boiling point of −133°F, compared to −423°F for liquid hydrogen. Callery also will use the plant for advanced work on monopropellants, bipropellants and solids.

Aerojet-General and **National Research Corp.,** Cambridge, Mass., have worked out an agreement for commercial, large-scale production of solid fuels. Aerojet will use certain vacuum processes, equipment and techniques developed by NRC.

For NASA's *Scout,* **Hercules Powder** has come up with third- and fourth-stage motor cases fabricated from plastic, reportedly light as magnesium and strong as steel. Third stage of the $500,000 rocket weighs 2200 pounds and the fourth stage weighs 500. Both are solid-fueled motors.

New Rocket Steel

Jones & Laughlin Steel Corp.'s Stainless and Strip Division, Youngstown, Ohio, has been awarded a contract by Aerojet-General to develop an extremely high-strength strip steel for missile and rocket components. Specs call for mechanical properties "far in excess" of available commercial strip.

Hardware for NASA's Wallops Island project to measure high-altitude radiation is **Aerolab Development Co.** *Javelin.* The first 49-foot, 7400-pound vehicle boosted a 45-pound instrumentation payload to 750 miles July 7. Six more firings are scheduled before year's end.

The solid-fueled four-stage sounding rockets are composed of modified *Honest John, Nike* and *Vanguard* components. Last four firings will be with a 60-foot model weighing 13,000 pounds and capable of carrying similar payload to 1650 miles.

Contracts & Companies

Development and evaluation contract for $36,000 has been awarded **Ultrasonic Testing & Research Laboratory,** Van Nuys, Calif., by WADC. Object: find non-destructive techniques for detecting defective areas in solid-propellant motors . . . BuOrd has contracted with **Clevite Corp.'s** Mechanical Research Division to investigate property modification of materials such as tungsten for ultra high-temperature missile applications . . . At Hicksville, L.I., **Radar Measurements Corp.** is at full operation in a new plant . . . **American Bosch Arma** has acquired **Ensign Carburetor,** Fullerton, Calif., a maker of fuel injectors and similar products . . . **Ford Aeronutronics Division** *Shillelagh* (tank-launched missile for close-in troop support) may be rechristened *Pentomic* . . . More expansion for **Raytheon** is in the works. The company which a few weeks ago announced new plants at Lewiston, Maine, and Portsmouth, R.I., now says it will build a wholly integrated electronic warfare center at Santa Barbara, Calif. The plan calls for expanding its existing operation there by 220,000 square feet of space and employing a total of 1700 persons by 1964.

TRW Acquires Magna

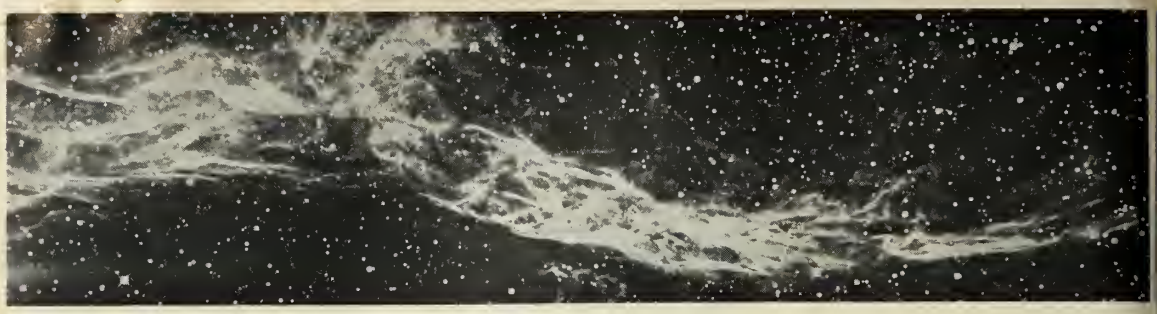
Thompson Ramo Wooldridge has purchased controlling interest in **Magna Products Inc.,** Santa Fe Springs, Calif., a specialty chemical and electronics firm which recently won a Navy solid propellant research contract . . . Air Force logistics manager for the as yet unchristened **Douglas** ALBM (WS-138A) is the Ogden Air Materiel Area, Hill AFB, Utah . . . **Packard-Bell Electronics Corp.** stock was listed on the New York and Pacific Coast Stock Exchanges last week for the first time . . . **Transval Electronic Corp.,** Culver City, Calif., now has Washington representation—Jack Campbell . . . For more missile assembly space, **Horkey-Moore Associates** is constructing a new 13,500-square foot building at Torrance, Calif. . . . At Gardena, Calif., the **Jetstream Fastener Corp.** is moving into a new 14,000 square-foot building . . . and **The United States Chemical Milling Corp.** has acquired **Darco Industries Inc.,** missile component producer with plants at Glendale and El Segundo.

IN THIS MULTIPLE UNIT

SUB-MINIATURE PULSE TRANSFORMERS

Designed and Built by Forbes and Wagner in Co-operation with One of the World's Largest Computer Manufacturers

Up to five sub-miniature pulse transformers are packaged in a single assembly for use in the IBM 7070 Computer. This unit measuring 1.80" x 1" x .312" is an excellent example of modular design. Skilled operators plus modern equipment are required to handle the extremely fine wire sizes which comprise the toroidal windings and very minute cores of the pulse transformers. Forbes and Wagner sub-miniaturized multiple packaging provides worthwhile dividends in simplification and economy.



Let us help YOU with YOUR Electronic Problems

We design and produce both simple and complex components and assemblies, Electronic, Electro-Mechanical and Mechanical for Commercial and Military applications in Radio, Television, Tele-communications, Computers, Radar, Guided Missilies and allied fields. Write for brochure giving complete information.

Growth Opportunity for Electrical Engineers. To meet the growing demand for our services, we offer steady employment, high base salary plus profit sharing, paid vacation, group life and hospitalization insurance, sick leave policy, retirement program, etc. Located on shore of Lake Erie. Fishing, boating, swimming at your doorstep. Ideal community life. Thirty minutes from Buffalo via thruway. Replies held in strict confidence.

Aluminum Bar Cuts Aluminum Weld Costs

A new type aluminum back-up bar or metal inert gas-arc welding of luminum is cutting costs and speeding roduction at the **Reynolds Metals ompany** missile plant at Sheffield, Ala.

The new back-up bar is of a ma-ineable aluminum alloy and has an asily replaceable T-shaped stainless eel insert. Previously, the back-up welding bars used in the plant were made entirely of stainless steel.

Charles M. Jenkins, production superintendent at the missile ballistic shell plant and leader in the development of the new back-up bars, said they offered two major advantages over conventional all-stainless bars:

One is that the aluminum bar dissipates the welding heat much more quickly than the stainless bars, making unnecessary the water jackets in use on some production stake welders. And faster heat dissipation keeps weldment distortion to a minimum.

The other major advantage is that the stainless steel inserts are cheap enough to be discarded after their grooves become burned and pitted.

Plant Manager M. C. Duke said the inserts can be replaced for less than half the average cost of repairing the all-stainless back-up bars previously used. There's also a definite saving in down time in the welding department.

Production is also speeded, Mr. Duke said, because inserts of different groove sizes for different sheet thicknesses can be put in much more quickly than was the case when the entire back-up bar had to be switched.

Reynold's missile plant has been using the new back-up bars for more than a year. It has not been necessary to replace any of the aluminum bars which hold the stainless steel inserts.

The aluminum bars and the stainless inserts can be produced either by extrusion or machining, plant officials said.

The Reynolds plant makes aluminum missile shells and tail sections for the *Redstone* and *Jupiter-C* vehicles. It also supplies aluminum in many forms for ABMA's *Jupiter* and many other rockets.

World's Largest Fly-Away uel Tanks Built for *Thor*

In a brand new hospital-clean dust-ee alloy manufacturing plant in the ntral manufacturing district of Los ngeles, more than 300 employees of **andard Steel Corp.** are building giant etal vacuum bottles for storage of uid oxygen, fuel for the Air Force's *hor* missile.

Installed at Vandenberg Air Force se in California, and flown to other *hor* launching sites around the world, ese tanks represent one of the most acting alloy fabricating jobs ever empted.

Standard Steel Corp. delivers the nks to **Douglas Aircraft Co.,** Santa onica, Calif., through the **Cambridge rp.** Designed to hold 13,500 gallons liquid oxygen at 297.4° below zero, ey have a high-strength (type 5086) minum outer jacket and a stainless steel (type 321) inner shell. Unusual fabrication techniques were developed so that the huge tanks, 52 ft. long and nearly 9 ft. in diameter, would be light enough to support 135,000 lbs. of liquid oxygen when full. They weigh 32,000 lbs. when empty. All of the ground support equipment for operational units of the Air Force *Thor* program is being built for fly-away shipment.

In Standard's new alloy fabricating plant, assembly of the vacuum bottle tanks is done in a dust-controlled room kept under slight pressure to prevent infiltration of dust. Concrete floors have been completely sand blasted and a special surface hardener applied to discourage dust accumulation. These floors are continuously vacuumed. All structural members, ceiling and walls are painted white. Welders and other skilled workmen don white uniforms, and special rubber-soled shoes have to be worn when working inside the stainless steel and aluminum shells.

After complete assembly and thorough cleaning, the tank is positioned on Standard's testing pad located at the new plant. Liquid oxygen fills the tank to the ¼ mark and is held for 72 hours to check vacuum readings. Final pressurization is done with dry nitrogen before the tank, supported by a trailer undercarriage, goes to Vandenberg or a nearby airport.

'Ribbon' Cable Has Specialized Applications

Multi-conductor cables in flat "ribbon" configurations for use in specialty and tight locations are now being produced in quantity by **Tensolite Insulated Wire Co., Inc.**

The cables are flexible in one plane, making it simple to run them around corners or around the inside edge of a container. This flexibility also makes them especially valuable for use with drawer pull-out type printed circuit assemblies.

One user has the cable installed on a spring-loaded spool which unrolls the cable as the board is slid out. Most major connector manufacturers make suitable ribbon cable connectors for the interconnection of these printed circuit boards.

The cables are frequently woven on looms similar to those used in the textile industry. Yarn ends—Teflon, Nylon, Fiberglass, Dacron, cotton or other textile fibers—form the "warp" and the "woof" or "filling." The wires would be analogous to the "stuffer" yarns in a carpet. They lie lengthwise in the ribbon cable. The interlocking, or weaving, of the "warp" yarns and "filling" yarns bind the wires in place.

Metallic "woofs" such as silver-plated copper, tinned copper and stainless steel are also available. Primary insulation of the wire can be either Teflon or PVC. Any number of twisted multi-conductors, coaxial cables, and single conductors as small as 36 AWG may be used. It is not necessary that the individual wires be of the same gauge. Color coding is possible on each individual conductor.

Resin Retains Strength After Exposure to 600°F.

A silane modified phenol-formaldehyde resin, which retains its strength after exposure to temperatures of 600° F for hundreds of hours, is available in commercial quantities from **Monsanto Chemical Company's Plastics Division.**

The new material, tradenamed Resinox SC-1013, was developed especially for use with fibrous glass and asbestos reinforcements to make radomes for supersonic aircraft. Because of its excellent performance in the 500 to 600° F temperature range, it is expected to be used in other applications where such temperatures have prohibited the use of plastics.

Radomes must be lightweight and "transparent" to radar beams, yet strong enough to withstand the high temperatures produced by a combination of high speed friction and the high-frequency radar impulses passing through them.

According to Thomas W. Sears Jr., sales manager for industrial resins, this is a critical problem area for which there has not been a satisfactory material. "Resinox SC-1013 has high frequency electrical properties and high temperature performance characteristics several times better than conventional phenol-formaldehyde resins and

In the deadly game of chance we call the cold war, there's no room for guesswork. We must know, every hour of every day, *exactly where our potential enemies' strength lies.*

Electronic Reconnaissance today is one of our major defensive weapons—incredible "eyes" with which we can not only detect enemy radar and missile guidance signals, but determine with precise accuracy the location, type and capability of the signal source as well.

The Hallicrafters company has been engaged actively in top priority research and development of Electronic Reconnaissance Equipments since 1952.

Looking for a challenging new opportunity? Recent increases in major contract work have created new openings for qualified engineers at all levels. For full details in confidence, contact William F. Frankart, Director of Engineering.

DEPENDABILITY

another outstanding attribute of

DIMAZINE®

unsym-Dimethylhydrazine, UDMH

THE STORABLE FUEL

Performance data on DIMAZINE-powered rocket engines in military missiles and satellite launching vehicles shows DIMAZINE to be a highly reliable rocket fuel.

DIMAZINE provides fast, dependable hypergolic starts followed by smooth, stable combustion and easier shutdowns. Dependable instant readiness is assured for years by its outstanding stability during storage in missiles. It also has high performance, high thermal stability, low freezing point, low shock sensitivity, minimum susceptibility to contamination and high compatibility with almost all metals and appropriate sealing materials.

These manifold advantages combine to make DIMAZINE *the outstanding storable fuel.* We will be pleased to work with you in evaluating DIMAZINE and to supply detailed data on its properties and handling.

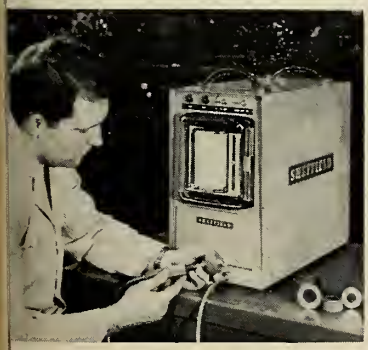
we believe that it will make important contributions to the development and use of high-speed radar domes," he said.

Late last year the company announced the development of a special phenol-formaldehyde resin, Resinox SC-1008, to protect missile nose cones against the super high temperatures, well above 10,000°F, generated by friction during the short period they are plunging through the earth's dense atmosphere from high altitudes.



Both products are the results of a special research program to develop materials for aircraft, missile and rocket parts and components at the company's resin products laboratories.

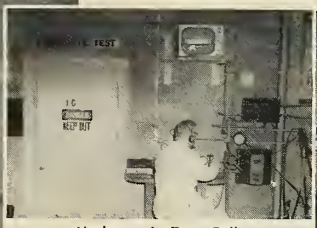
Instrument Air Gages and Records Simultaneously

Data gathering for dimensional quality control charts or a chartered record to serve as a size certificate can be made faster and to machine accuracy with a new gaging and recording instrument recently developed by **The Sheffield Corporation.**

The new instrument, which uses hand or fixture-type air gage tooling, makes an automatic record showing a part's plus or minus deviation from nominal size on a 4" wide strip chart

during gaging. The standard model is supplied with continuous chart drive and will inspect a single dimension.



Where desired, the Air Gage Recorder can be obtained also to check two dimensions as well as being equipped with optional features such as maximum and minimum signal lights, and an index drive to move the chart approximately 1/8 of an inch on each gaging operation.

Back-pressure type air gage tooling is used as the size-sensing elements, including Open-jet, Balljet, and Blade jet spindles, Air Snaps and Air Rings,

all you need

to store NITROGEN TETROXIDE

is a rocket

This liquid-fuel oxidizer needs no refrigeration, causes no freeze-ups

As an oxidizer for liquid fuels, Nitrogen Tetroxide has even more to recommend it than its high performance (99% of theoretical I_{sp}, hypergolic at low altitude). The ease with which it can be stored and handled offers another major advantage.

N_2O_4 requires no refrigeration, no high-pressure vessels. It is noncorrosive, can be stored indefinitely in plain carbon steel tanks at the launching site or right in the rocket itself. And it's ready when it's needed—there are no freeze-ups in valves and motors with N_2O_4.

Availability: excellent. Allied is a major producer of Nitrogen Tetroxide, can ship immediately in cylinders or tank car lots. Allied also produces ammonia, ethylene oxide and methanol for the rocket industry. Write for technical or other information you desire on any of these products.

For specifications and local offices, see our insert in Chemical Materials Catalog, pages 435-442 and in Chemical Week Buyers Guide, pages 35-42.

BASIC TO AMERICA'S PROGRESS

Allied Chemical

NITROGEN DIVISION
Dept. NT 5-12-1, 40 Rector Street, New York 6, N. Y.

and Plunjet gaging cartridges. Existing flow-type tooling up to 2000 to 1 amplification generally can be modified to suit the instrument.

The new inspection-recording device is the approximate size of a portable TV set, measuring 9½" wide x 19½" deep x 17" high. It connects to the regular factory air line and 110 volt, 60 cycle ac. The back-pressure gaging unit, air pressure regulator, and pen and ink strip chaet recorder are housed in the modular-type unit which has a Plexiglass window at the front for viewing the chart.

The present non-automatic "hand and eye" method, in which the "eye" notes the gage reading and the "hand" writes the figure down on a tally sheet, has a number of inherent weaknesses. For example, production-conscious personnel may not make the actual number of checks required for a true statistical sample.

Data tally sheets can be filled out by checking just a few parts and then extending the trend or by writing in similar figures for the rest. Also, hand written figures are often illegible, hard to read, subject to error in transcribing, and they can be changed. As a result, the success or failure of a quality control program may depend, in final analysis, on the accuracy with which the original gage data is recorded.

This is one of a series of informative messages to acquaint engineers and scientists with the projects of RCA Moorestown.

RCA MOORESTOWN AND THE WORLD'S MOST ACCURATE RADAR

At its Moorestown Engineering Plant, RCA has developed an instrumentation radar that has created an entirely new order of precision in radar tracking. Standardized by the Secretary of Defense for use on operational and training ranges of all three services, the AN/FPS—16 is acknowledged to be the world's most accurate radar.

The AN/FPS—16 provides accuracies even far beyond those obtainable with precision optical devices at moderate distances and under favorable atmospheric conditions. A higher magnitude of performance is combined with immense versatility and capability for instant reduction of data to visual display and recording in graphic or digital form.

The AN/FPS—16 uses amplitude-comparison monopulse tracking, rather than conical-scan tracking. The success of this radar has helped to establish RCA Moorestown as the leader in the field of precision monopulse trackers. The performance of this radar cannot be explained merely by the inherent advantages of monopulse technique. Behind this performance lies a record of imaginative conception and planning, thorough theoretical analysis, and expert electrical and mechanical design.

Engineers, scientists and managers interested in contributing to the advanced projects now underway at RCA Moorestown are invited to address their inquiries to Mr. W. J. Henry, Box V-13G.

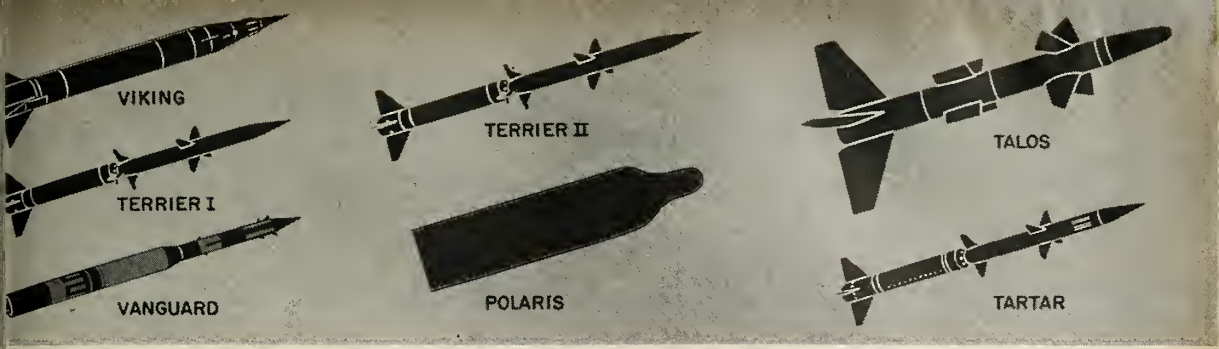
Advanced Steam Cleaner Has Support Applications

An advanced steam cleaner, designed initially for missile ground support equipment application, has been put into production by the **Kelite Corp.**

Designated the Mark IV, the new unit may be used to clean and phosphatize large structures such as missile launching ramps prior to painting. The steam gun design which supplies hot cleaning and phosphatizing solution at 600 gallons per hour, is reported to eliminate the disadvantages of former syphon gun equipment. The machine may also be used for high-capacity



steam cleaning operations and/or high-pressure water rinse.

The Mark IV is available in both direct fired (gas) and fireless models. Latter may be used if a steam source is available. Direct fired model operates on either city or bottled gas. To conserve cleaning solution and personnel time, the gas supply and positive displacement pumps are controlled by a lever at the steam gun.

...new missile products

Two inches in diameter and 2¾ inches long, these components consist principally of a gyro motor, a torque motor, a signal generator, and a constant damping device. Unique design combines the torque motor and the signal generator in a single unit, or "torsyn," together with a restraint-trimming tertiary winding.

The gyros are said to exhibit performance characteristics that are superior to those of any other unit of comparable size now in use. Designed for maximum adaptability to precision mass productions methods, these gyros can be produced having a variety of performance characteristics tailored to specific applications.

There is said to be no limit to the altitude at which these components operate, and no performance deterioration with altitude.

Performance Characteristics: Mass unbalance, 1°/hr. max. untrimmed (along input and spin axes); Restraint: 0.5°/hr. max. untrimmed; Standard deviation (short term); azimuth—.05°/hr.; vertical—.03°/hr.; Max. drift rate: .015°/hr./g^2 steady accel.; .008°/hr./g^2 vibratory accel.; Damping: input-output angle ratio - 0.2; Characteristic time: .0035 sec. or less; Gimbal freedom: ±3° minimum; Warmup time: 10 minutes from –60°F; Weight: 0.7 lbs.; Life: 1000 hrs.

Simplified 5 Volt Recording System Produced

A simplified 6- or 8-channel direct writing oscillographic recording system has been developed by **Sanborn Company** specifically for computer readout, telemetry recording, dc monitoring and similar applications requiring no preamplification.

The Sanborn Model 358-5480 system consists of a 6- or 8-channel control panel for input signal control and a 6- or 8-channel recorder-amplifier unit.

System linearity is 0.5% of full scale (max. chart width 50 divisions); sensitivity is 0.1 volt/division; frequency response is 3 db down at 150 cps at 10 division peak-to-peak amplitude. The system has hysteresis of less than –0.1 division and gain stability better than 1%.

The control panel provides position, smooth gain and attenuator controls, and an internal calibration signal. Single-ended input connections of 100,000 ohms impedance can be made either on the front or the rear of the cabinet.

Pressure Regulator Has Integral Relief Valve

The development of Model 30-301 Dynectics Pressure Regulator with a built-in relief valve has been announced by the **Applied Dynamics Corporation.** Typical applications of the unit include airborne or ground electronic system pressurization, air or gas system pressure control.

The model 30-301 regulator is designed for control of system pressure. Function of integral relief valve is to prevent pressure build-up due to thermal expansion of air or line surges.

The regulator is designed for: an inlet pressure of 40 to 60 psig and an outlet pressure of 15 to 30 psig, a burst pressure of 500 psig at inlet and 80 psig at outlet, a pressure variation

SYSTEM DEVELOPMENT CORPORATION

urrently seeking scientists and engineers in various skill areas. part of this effort, I have been given the opportunity to tell you ething about our organization.

t me begin by giving you some general facts about the Corporation: C is a non-profit organization chartered to work in fields aining to public welfare, the advancement of science, and onal defense. The Corporation's name implies its function—the elopment of systems. Specifically, we are concerned with large, plex information processing systems with a high degree of mation. Development of these systems is accomplished through application of knowledge in the areas of applied mathematics, ineering, and psychology, to problems of over-all system design, processing techniques and optimum man-machine relationships.

ur work is system-oriented, rather than concerned with the ign or manufacture of hardware components. As a result of this of specialization, we have assumed major responsibilities in the elopment of systems such as the SAGE (Semi-Automatic und Environment) Air Defense System and the world-wide itegic Air Command Control System, and in the integration of functional responsibilities of these systems with other military tronic support systems.

cause the scope of our activities is rapidly increasing, we are anding our staff. In this message I am specifically addressing ng engineers with advanced training and proved analytical ity in the areas of weapons system analysis, noise and rmation theory, ECM, electromagnetic intelligence and allied ds. If you are qualified, and our corporate activities sound resting to you, we would like to hear from you. Address inquiries arding our Santa Monica, California facility to Mr. R. W. Frost, 4 Colorado Avenue, Santa Monica, California. Inquiries regarding Lodi, New Jersey facility should be addressed to Mr. R. L. Obrey, 2651, Grand Central Station, New York 17, N.Y. These gentlemen see that your letter receives prompt attention and confidential tment."

Tiny Radar Device Can Fit Into Attache Case

A miniature radar-like device that detects and measures movements up to thousands of feet away was demonstrated here publicly for the first time today by the **Singer Military Products Division.**

Named the Standing Wave Area Motion Indicator (SWAMI), the device is small enough to fit into an attache case and is virtually impossible to confound with countermeasures.

The SWAMI sensor is a sealed vacuum tube envelope containing an ultra-high-frequency radio oscillator pulsed at a low-frequency repetition rate. This apparatus is shock-resistant, and its service life will compare favorably with that of vacuum tubes used conservatively in more conventional applications.

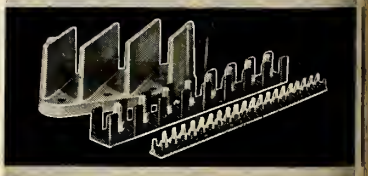
Any motion in or intrusion into the area under surveillance induces a change in the low-frequency repetition rate which, in turn, is detected by an FM detector. The detector transmits this intelligence to the monitor in a central control station in the form of voltage fluctuation of high amplitude, touching off the alarm.

Any attempt to tamper with the connecting cable leading from sensor to monitor will actuate the alarm.

Power source for the sensor may be either an ordinary household 115-volt outlet or a battery with enough power to supply an ordinary household night light. Any type of battery, wet or dry cell, will serve.

A SWAMI unit has effective range from a few inches to several thousand feet and, operated without auxiliary equipment, is omnidirectional. However, the propagation angle may be reduced by installation of a reflector around the antenna. The practical lower limit for portable, highly mobile units, such as might be carried in the field by light infantry, is approximately 15 degrees.

Restriction of the propagation angle would be desirable, for example, if friendly activities were to be carried on within range of the SWAMI. The instrument would then be focused through a narrow angle covering only the area where a hostile movement is anticipated, but would be screened off in such a way that it would not respond



high temperature
PLASTICS

Continuing research in the field of high temperature plastic molding has enabled Olympic to create fiberglass missile components such as nose cones, radomes and heat reflective shields.

High strength, heat resisting structural parts and exhaust deflectors, insulators and nozzles have been produced that perform as high as 5000° F.

Standard electrical terminal strips now adopted as NAS 1066, as well as special design terminal blocks, have been developed to withstand continuous service to 600° F.

OLYMPIC Plastics Company, Inc.
3471 S. La Cienega Blvd., Los Angeles, Calif.

Circle No. 73 on Subscriber Service Card.

to intentional activities elsewhere within the normally effective range of operation.

Relative speed of a target can be determined with a single SWAMI unit, and, if the instrument is positioned to focus directly along the line of motion, it will determine the absolute speed. A unit could be beamed directly along a straight stretch of highway so that traffic is moving directly toward or away from the instrument, and a count of the half wavelengths read as a calibration of absolute speed.

Units positioned within range of one another will act in a complementary way to reinforce the amplitude of each.

In line with a sustained effort to diversify its product line in the military field, Singer-Bridgeport several months ago entered into an agreement with the **Product Development Corporation,** of Boston, an organization which specializes in helping private concerns find new products it can manufacture and sell profitably. Singer-Bridgeport said its acquisition of the right to SWAMI were directly attributable to operations of PDC.

New 5000° R&D Furnace Available

A resistance furnace for laboratory use, which operates to 5000°F and costs only 1/3 the amount of comparable furnaces, is available for immediate delivery from the **Curtiss-Wright Corporation.**

The furnace uses an inert gas for interior atmosphere with a graphite heating element and carbon insulation. It can be readily modified for special use for materials testing or processing studies.

The standard Curtiss-Wright unit has a heating chamber 4″ in diameter by 8″ high. The size of the chamber can be varied to meet specific requirements. Large production units have been designed for special processing needs. A hearth lowers out of the heating chamber for easy access to the interior of the unit. Two sighting tubes, at top and side of the furnace, allow sighting for temperature readings and automatic control purposes.

Outside dimensions have been held to a minimum and are only 12″ diameter x 24″ high.

The furnace is available with or without automatic temperature controls. However, power supply, gas control valves, pyrometers and necessary fittings for cooling are included so that the furnace is a self-contained unit. Power input is 15 kilowatts, at a temperature of 4500°F. With standard power supply, a maximum temperature of 5100°F is attainable.

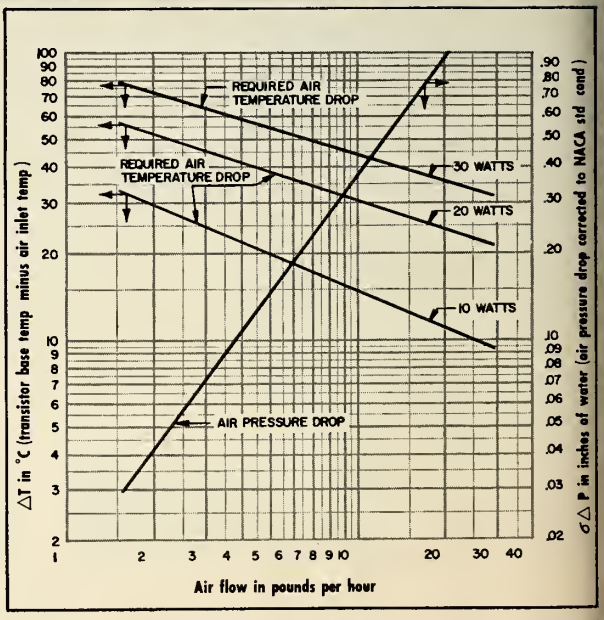
USE STOCK UAP

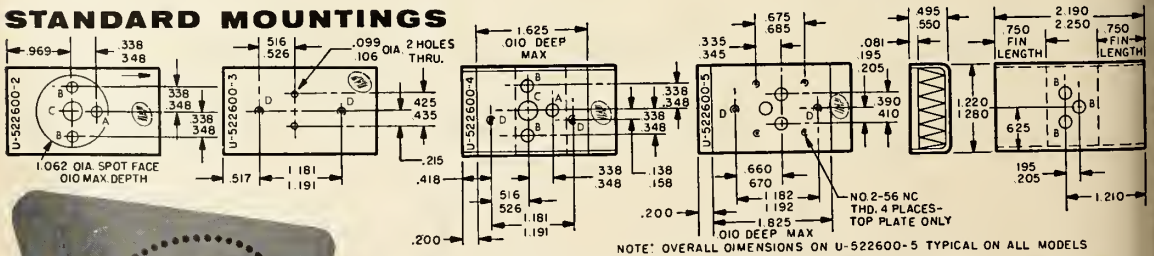
COLD PLATES

FOR COOLING

TRANSISTORS/DIODES



JEDEC* Nos. Transistors TO-3; TO-6; TO-10; TO-13; TO-14; TO-15; TO-26; TO-31; Diodes DO-4; DO-5.
**Joint Electronic Device Engineering Council*



Now, you can use *stock* UAP aluminum cold plates to control heat generated by power transistors and diodes used in electronic circuits. Heat is transferred by conduction through the mount to cooling air forced through the cold plate. Cooling air can be ducted from any suitable source.

Adaptability of this cold plate to specific cooling requirements can be easily determined. The maximum allowable transistor or diode base temperature and dissipation must be known or calculated. Then, using any one of the three parameters on the curve, the remaining conditions are indicated. Example: Using a transistor base temperature of 71°C at a dissipation of 20 Watts, and assuming air inlet temperature of 36°C, gives a △ T of 35°C, an air flow of 6.4 lbs./hr., with .20 inches of water pressure drop.

Overall envelope dimensions are 2.250″ length, 1.280″ width, .550″ depth. Weight, approximately 1 oz. Finish, alodine. For complete information on prices and delivery, call, wire or write direct to UAP.

STANDARD MOUNTINGS

NOTE: OVERALL DIMENSIONS ON U-522600-5 TYPICAL ON ALL MODELS

Hole "A" .185—.197 dio., top plote only; Hole "B" .185—.197 dia., both plotes; Hole "C" .279—.291 dio., both plotes; Hole "D" 5—40NC thds., top plate only.

Expanding the Frontiers of Space Technology in

FLIGHT TEST

■ Flight testing is conducted by Lockheed Missiles and Space Division in a unique manner. All components and sub-systems of a new project are initially tested on known-performance, production missiles. Thus, when the final system is ready for first flight, its individual components already possess flight-tested reliability.

This new concept of flight testing is of major significance and has enabled Lockheed to produce extremely complex missile systems in record time and at greatly reduced expense.

Actual testing is conducted at Cape Canaveral, Florida; Vandenberg AFB, California, and Alamogordo, New Mexico. Underwater launch tests for the Navy POLARIS FBM—including studies of cavitation, wave simulation and skip motion—are carried on at the Sunnyvale facility and at the Navy test base on San Clemente Island. In addition, structural and certain restricted flight tests are performed at Hunter's Point Naval Shipyard, San Francisco.

ENGINEERS AND SCIENTISTS

Lockheed Missiles and Space Division programs reach far into the future and deal with unknown and challenging environments. If you are experienced in one or more of the above areas, or have background in related work, we invite you to share in the future of a company that has an outstanding record of achievement and make an important individual contribution to your nation's progress in space technology. Write: Research and Development Staff, Dept. G-3-29, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship required.

contact and resistance to corrosion. Plastic parts are molded of durable nylon for high dielectric strength and excellent resistance to corrosive chemicals, oil and grease, abrasion and impact, chipping and cracking.

Both plugs and receptacles are available in red, white, blue, black, yellow and green. For maximum flexibility, plug wiring can be either by soldering or by fastening with two cable fastening screws. Socket plug grips are of a simple, two-piece threaded construction for quick assembly. Pin plugs are assembled by a single nut after cable connection.

Receptacles have color-matching caps and bodies to permit more rapid and accurate circuit identification in front and back of panel.

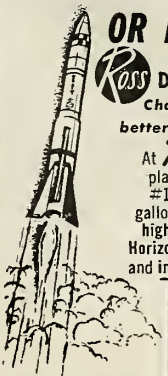
'One-Way' Mercury Switch Now Available

A new type of mercury switch has been announced by **American Designed Components, Inc.** Because of its novel construction, the Type UZW switch controls mercury flow in such a way that a momentary wipe contact is produced when tilted 10 degrees or more in one direction, with no contact upon return to original position.

Using this basic orifice principle and inserting additional electrodes permits the company to offer a variety of circuit arrangements. For example, two wipe contacts and two make/break contacts may be incorporated into a single switch.



A standard-size switch measures less than 2¾" in length, less than ½" in diameter. It is capable of carrying 5 amp at 115 v, with inrush overloads of up to 10 amp. Even smaller sizes and tilt angles are available to suit specific requirements. The switch is unusually low in cost for this type of circuit arrangement; average list price is $2.

AM-DE-CO mercury switches offer several unique advantages. By using a special hard glass and solidly fused-in ceramic spark shields, operating capacities of up to 100 amp and inrush overloads to 500 amp may be handled, at temperatures up to 250°F. Being hermetically sealed, these switches offer positive precision control for many types of equipment.

Typical examples are paint sprayers, washing machines, waste disposal units, oil burners, pumps and compressors, textile machinery, welding apparatus, motors and generators.

periscopes for canaveral's bunkers

With their viewing heads protruding from the domed bunkers at Cape Canaveral, Kollmorgen bunkerscopes provide a vital visual link between the launching pad and the observer. These instruments, used during launching operations and static tests, present images in true color, offer dual magnification and allow detailed observation in complete safety. They are ruggedly constructed to resist blast forces. Easy to operate, personnel need little if any special training in their use. Bunkerscopes require virtually no maintenance. Also, initial costs are generally lower than with other types of remote viewing systems. These instruments are easily adapted to photography and television purposes.

Working with optics, mechanics and electronics, the Kollmorgen Optical Corporation designs and manufactures many different types of remote viewing, inspection and testing instruments and systems. For a new illustrated brochure write Dept. 107.

Potentiometer Uses Carpenter's Level Bubble

Hamlin, Inc. announces the introduction of a new EP 1012, Gravity Sensing Electrolytic Potentiometer which provides operation dependent upon the motion of an air bubble in a curved glass tube, similar to that found in a carpenter's level.

Three electrodes are sealed in a curved glass tube which is partially filled with an electrolytic solution. Electrodes are arranged so that when unit is in a horizontal position, the resistance from the two operational electrodes to the common electrode is equal. When unit is tilted, air bubble moves, causing resistance to increase on one operational electrode and decrease on the other.

If the EP 1012 is used as one-half of a bridge circuit in a 1000 Ohm bridge, with 12v applied, zero output results at the horizontal position. Tilting the unit ¼°, 4v of output results and at ½°, 8v. Designed to give an error signal with a small amount of deviation from the horizontal, unit reaches saturation at approximately ¾°.

Hydraulic Actuators Have Support Applications

A new line of rotary power hydraulic actuators has been introduced by **Vard, Inc.,** a subsidiary of **Royal Industries, Inc.,** Pasadena, Calif.

The actuators have an unusually high torque/inertia ratio and are designed especially for critical ground applications. They provide power for rotary vibration testing, angular load testing and high-powered angular positioning in flight simulation tables and missile exercise launching and handling equipment.

Model 30-87-120 is in depth 8" x 8½" wide and has a dry weight of 36 lbs. Its stall torque at 3000 psi in 8700 in-lb. and its internal leakage is .20 gpm. There is no internal snubbing in this model and its frequency response is rated at 0-200 cps.

The stall torque of Model 30-100-90S is 10,000 in-lb. at 3000 psi. This model, 7¾" x 8⅝" with a dry weight of 50 lbs., has 15-degree internal snubbing, .25 gpm internal leakage and a frequency response of 0-200 cps.

Last in this new series is Model 30-190-120, 10 3/8" x 10", with a dry weight of 80 lbs. Its stall torque at 3000 psi is 19,000 in.-lb. with no internal subbing.

General Chemical offers Helpful Technical Data on ROCKET FUEL OXIDIZERS

- ✓ Fuming Nitric Acid
- ✓ Liquid Fluorine
- ✓ Chlorine Trifluoride and other Halogen Fluorides

To assist specialists working in the field of rocket and missile propulsion, General Chemical now offers a valuable set of product information bulletins packed with physical and chemical data, tables and graphs. This information is based on General Chemical's extensive experience with these products as America's leading producer of fluorine and fluorine-based chemicals, and one of the nation's primary producers of nitric and other mineral acids. The questions our customers ask most often about these products are answered here.

Here are the specific bulletins offered:

"Nitric Acid, Fuming"—29 pages—Including detailed product description of both red and white fuming nitric acid, chemical and physical properties, corrosion data, directions for storage and handling.

"Fluorine"—21 pages—Including extensive data on the chemical and physical properties of this most powerful oxidizing agent, a description of materials and equipment for handling gaseous and liquid fluorine, safety precautions.

"Chlorine Trifluoride"—35 pages—Including the chemical and physical properties of chlorine trifluoride and other halogen fluorides, recommended materials for use in halogen fluoride systems, directions for safe handling.

Also available are bulletins on:

Handling Elemental Fluorine Gas In The Laboratory
Liquid Fluorine Unloading Procedure
Chlorine Trifluoride Vapor Pressures

Mail coupon now for your free copy of any or all 6 of these valuable technical bulletins.

Flow Before Flight . . . Controlled by Crane

At that critical point in launching preparations when liquid fuel is released to the missile on the pad, the valve that's opened is likely to be a Crane cryogenic globe valve.

Since 1855 it has been traditional with Crane to pioneer in valves for the newest applications in the newest industries. This leadership, together with Crane product quality and dependability, has made Crane the world's largest manufacturer of valves.

Whether your need is for special valves for missile fuel handling—or valves for a more "down-to-earth" application in the control of water, steam and air—Crane can meet all your specifications.

You will find the Crane handbook "Valves for Guided Missile and Rocket Services" very helpful in specifying for liquid fuels, gases, and other fluids used at launching pads, test stations and operating bases. Request your free copy, on your business letterhead, from your nearest Crane branch or write to address below.

contracts

ARMY

$7,309,594—**Hughes Aircraft Company**, Fullerton, Calif., for 12 months' development work to improve the Missile Monitor antiaircraft defense system.

$1,937,078—**The Martin Company**, Orlando, Fla., for fire intergration equipment in conjunction with the Missile Master system.

$1,002,477—**Minneapolis-Honeywell Regulator Co.**, Hopkins, Minn., for a classified project.

Dynatronics, Inc., Orlando, Fla., has received a "more than a quarter of a million" dollar contract for research, development and production of a complex camera timing system to be used on the Atlantic Missile Range.

$600,000—**Avion Div., ACF Industries, Inc.**, Paramus, N.J., for production of radar beacons (subcontract from **Radio Receptor Co.**).

$59,800—**Strand Engineering Co.**, Ann Arbor, Mich., for data recorder.

NAVY

$6,000,000—**The Martin Co.**, Orlando, Fla., for production of *Bullpup* air-to-surface missiles for the Air Force.

$539,100—**Dale Benz, Inc.**, San Diego, for construction of *Nike-Zeus* test facilities, Point Mugu, Calif.

$392,499—**Atlantic Research Corp.**, Alexandria, Va., for research to design a rocketsonde system.

$385,295—**Minneapolis-Honeywell Regulator Co.**, Minneapolis, for 160 altitude control kits for M-1 autopilots.

$144,086—**General Mills, Inc.**, Minneapolis, for research on defense against ballistic missiles.

$136,532—**Technical Operations, Inc.**, Burlington, Mass., for research on defense against ballistic missiles.

$129,750—**Consolidated Systems Corp.**, Monrovia, Calif., for telemetry data processing system.

$100,761—**Industrial Research Associates, Inc.**, Baltimore, for research on defense against ballistic missiles.

$97,191—**Fairchild Engine & Airplane Corp.**, Alexandria, Va., for engineering services, facilities and materials necessary to conduct studies of the Pacific Missile Range.

$93,895—**Chance Vought Aircraft Inc.**, Dallas, for study of Roosevelt Roads Guided Missile Training Range.

$80,000—**University of Michigan**, Ann Arbor, for research on hypersonic flow with dissociation and ionization.

AIR FORCE

Radiation, Inc., Florida Division, has received a "multi-million" dollar contract for an advanced digital telemetering system for the *Minuteman* missile program (subcontract from **Boeing Airplane Co.**).

$[illegible],667,000—**Ryan Aeronautical Co.**, San Diego, for production of the advanced version of the *Firebee* target missile.

$8,000,000—**Airborne Instruments Laboratory, Div. of Cutler-Hammer, Inc.**, for 20 pieces of equipment designed to eliminate unwanted interference on radar screens used in the SAGE air defense system.

$6,500,000—**Vitro Laboratories, Div. of Vitro Corp. of America**, N.Y., for operation and maintenance of the Eglin Gulf Test Range for the Air Proving Ground Center.

$5,000,000—**Hoffman Laboratories Div., Hoffman Electronics Corp.**, Los Angeles, for production of specialized test equipment to be used with TACAN.

$1,017,028—**Del Mar Engineering Laboratories, Inc.**, Los Angeles, for target system, external tow, rocket and missile, type A/A 37U-2, 66 each, technical and engineering data and related spare parts.

$209,000—**RCA**, Moorestown, N.J., for one real time data handling system and ancillary equipment and data.

$102,540—**Continental Electric Co.**, Geneva, Ill., for various electron tubes (two contracts).

$84,000—**Eitel-McCullough, Inc.**, San Carlos, Calif., for various electron tubes.

$71,250—**Sylvania Electric Products, Inc.**, N.Y., for various electron tubes.

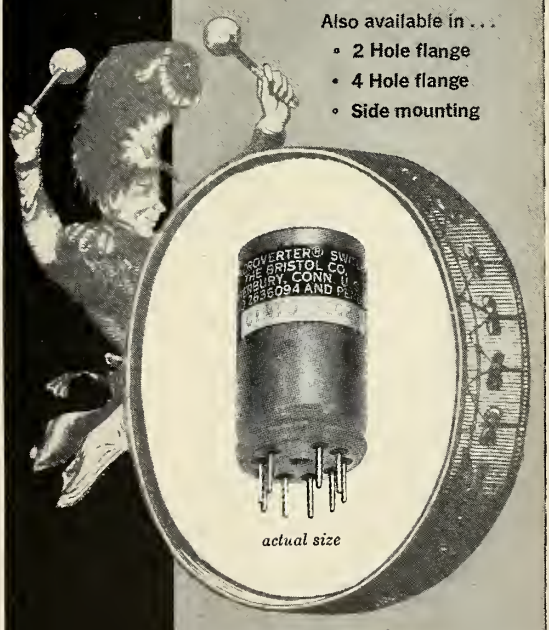
$58,000—**University of California**, Berkeley, for research on "tolerance and adaptability of the brain to environment imposed by space flight."

NASA

Hercules Powder Co., Philadelphia, has received a contract to supply fuel and plastic case for the third and fourth stages of Project *Scout* rocket (amount not disclosed).

MISCELLANEOUS

$2,250,000—**Federal Pacific Electric Co.**, New York City, for 5 kv metal-clad switchgear, control consoles and low-voltage controls for diesel generating units for missile launching and tracking facilities.



$642,986—**Microwave Associates, Inc.**, Burlington, Mass., contracts include one from the Navy for study and development in the field of Varactor diodes and parametric amplifiers, and two from the Air Force for design and development of a parametric amplifier for radio-astronomy use and microwave switching tubes.

$250,000—**Hallamore Electronics, Division of The Siegler Corp.**, Los Angeles, for design and production of a complex radio frequency signal generator for use in an advanced air-to-air missile (subcontract from **Hughes Aircraft Co.**).

propulsion engineering

Missile applications of flame-plating . . .

are spelled out for M/R by H. V. Mosby, new products department, **Linde Company** division of **Union Carbide Corp.** (See this column, March 30.) Among the propulsion applications, Mosby suggests combustion chamber plating, pump seal coatings, valve coatings, fuel injector rings. Here are details on these "Plasmarc" applications:

Liquid-fuel combustion chamber . . .

can be plated internally with tungsten carbide or other metallic carbides to reduce erosion and oxidation, improve performance and reliability. The plasma arc process can apply aluminum oxide coatings to high-performance engines to cut down overheating and reduce problems caused by corrosive fuels.

Turbine pump shaft seals . . .

plated with tungsten carbide can operate at high rpm in hot gas environments. Mosby says parts flame-plated with tungsten carbide operate up to five times longer than chrome-plated parts.

Valves . . .

plated with aluminum oxide show considerable improvement in controlling hot gas flow.

Fuel injector rings . . .

can be flame-plated with tungsten carbide to eliminate localized hot spots that develop during ignition and cut-off. Without plating, fuel injector rings often are scarfed by impingement of oxygen or fuel mixtures rich in oxygen.

Tungsten carbide and aluminum oxide . . .

are only two of the coatings that can be applied by the flame-plating process. Actually, Mosby says, coatings can be made from almost any material that does not decompose on melting. Some materials available now include tantalum, molybdenum, palladium, platinum, rhenium, zirconium diboride. Also, some of these combinations can be flame-plated: tungsten alloyed with chromium, molybdenum, rhenium; tungsten blended with zirconia, alumina and other metal oxides. Linde Company says its scientists are making rapid progress on many other types of high-temperature coatings.

Plasma arc coating . . .

works this way: Oxygen and acetylene are fed into a special "gun." Powdered particles of the desired coating are then fed in and suspended in the mixture. Following ignition, detonation takes place, the detonation wave carries the particles at 10 Mach through the gun barrel to the surface to be plated. At the same time, the detonation heats the particles to plasticity. When they hit the surface to be plated, the particles embed themselves in the surface, and a small welding action takes place at the site.

Temperatures are reasonable . . .

although temperatures inside the equipment or "gun barrel" reach 6000°F, the surface temperatures seldom exceed 400°F. This means that the material to be coated gets hot enough to do the job—to embed and adhere—but the surface under treatment does not get hot enough to warp or to change its properties. Linde says this about finishes produced by the technique: "Flame-plated coatings have an as-coated smoothness of 125 microinches rms, and can be finished down to better than one microinch rms." Coatings have a porosity of less than 1%.

Tools for the industry . . .

will be made better, also thanks to the plasma arc technique. Tools can be made temperature-resistant, harder, corrosion-resistant with flame-plated coatings. Examples: Spindles, bushings, gages, mandrels, dies, and core rods.

—letters

Praise for Reporting

To the Editor:

In your June 22 issue, the article "Prospects for Thermoelectricity" by Hal Gettings is of extreme interest to my department here at **Westinghouse, Aircraft Equipment Department,** Lima, Ohio. I would like to reproduce this article for the education of our Sales and Engineering personnel.

Incidentally, in my personal opinion the article is more comprehensive than any I have read to date on this subject. Please accept by sincere congratulations on a fine piece of reporting.

Stan McNair
Advanced Systems Application
Department, AED Sales
Westinghouse Electric Corp.

Units—Another Viewpoint

To the Editor:

There seems to be much concern about the use of units in astronautics (M/R, April 27, p. 21). This is of course not a new situation—it has indeed been with us in physics, chemistry and technique for a long time.

Basically, there are two ways to develop a system of units:

1. The "naive" way—you just want to give factual information regarding velocity, time, place, etc.

Here any accepted and well-defined unit is sufficient. The metric systems are in this class—the use of nonmetric systems should be recommended, because their definitions are often unprecise (knot, foot, etc.)

Furthermore, convenience is the only other criterion—avoid all philosophy. So we demand such simple conversion factors as one, or powers of ten. The metric system again is clearly superior to the nonmetric systems.

2. The "theoretical" way—the number shall give ready information about the nature of the measured phenomenon. Mach number is an outstanding example.

In astronautics the analogue to the velocity of sound seems to be the parabolic speed. As this is a strong function of distance, and ill-defined in practical multi-body problems, its scientific meaning is not very pronounced. Therefore, besides the statement that a certain velocity is clearly hyperbolic, etc., no system of units should be built around parabolic velocity.

Reference to the speed of light is not to be recommended at all because of the uncertainity of the unit. "Einstein-Numbers" can be defined in various ways, but are obviously of little concern today. If one wants to use them, clear definitions as to coordinate system and way of measurement are mandatory. Summarizing, it is my feeling that in this fundamentally less-precise Class Two we do not need more than the elliptic, etc., velocity, or for very advanced work some kind of well defined Einstein number.

Sometimes of course the nature of the phenomenon being considered forces us to use a special set of units, because the knowledge is better in this set than in any other. A good example is the distance-measure "Astronomical unit" within the solar system: This of course disguises only lack of knowledge, because whenever this situation arises, the unit itself is not well known. Still it may be practical to use the "natural units" (Astronomical Unit, year, etc.), but then again there is no speculation about the "best system of units." This question has meaning only for one particular problem, eg. motion is the solar system.

There is only one basic weakness of the metric system of units—the units of time are nonmetric. As it seems to be extremely difficult to change this because of its world-wide use, there appears to be no room for a better system. Just another system will only add to the confusion without improving the situation.

Difficulties arising from units of mass and force, and some others in the electromagnetic field, have their source partly in inconvenient names, and partly in lack of training or understanding.

"To get small numbers by convenient units" is of course a fallacy, as meaningless digits can always be expressed as an exponent of a convenient base, usually

INHERENT HIGH SPEED CAPABILITIES • SUPERIOR CONTAMINATION TOLERANCE • HIGH RELIABILITY

The rugged, simplified construction of Bendix® hydraulic pumps plus precision production and quality control experience provide pumps with increased reliability for missile and aircraft systems. Smaller envelopes permit interchangeability with existing installations and compact packaging for new applications. Thousands of hours of endurance, qualification and flight testing have proven the Bendix family of hydraulic pumps will exceed all existing customer and military requirements.

Pumps are furnished as separate components or as an integral part of complete sub-systems. Standard pumps are furnished with forged aluminum housings for temperatures up to 400°F. and pressures up to 4,000 psi. Previous qualification of pumps for 550°F. assures you of high reliability for lower temperatures and availability of proven pumps for high temperature systems.

Advanced engineering, laboratory, precision manufacturing and complete service facilities are available for producing and servicing Bendix hydraulic pumps. This assures you of a quality pump manufactured specifically for your application.

All pumps are assembled and tested in a new air conditioned, humidity-controlled, dust-free area assuring contaminate-free pumps as delivered.

MAJOR PRODUCTS—aircraft and missile hydraulic pumps; hydraulic components and sub-systems; engine fuel pumps and fuel system components; precision bellows and bellows assemblies; thermostats and related sub-assemblies; and sub-contract manufacturing and brazing.

La Crosse, Wis.

Air Force Ballistic Missile Div., Los Angeles 45, Calif., and the Los Angeles District Corps of Engineers . . . Ed.

Operation Skycatch

To the Editor:

We were quite pleased with the fine treatment you gave us on the index page of your May 18 issue on our "Operation Skycatch" concerning the *Polaris* launching system.

I did want to point out one small error in the caption, however, in case any of your sharp-eyed readers should pick it up. In the last sentence of the caption, you indicated that **Westinghouse** was the prime contractor under **Lockheed** for the launching system. Actually, Westinghouse is prime contractor under the Navy for the development of the launching system for the *Polaris*.

R. V. McGahey,
Manager
Technical Publicity
Westinghouse Electric Corp.
Pittsburgh, Pa.

Facing the Facts

To the Editor:

I should like to express my appreciation of what may be called the "boldness" of information given through M/R. Information concerning the rocket field offered by our daily newspapers seems to be a playing ground and training ground for little would-be Joe Goebbelses particularly ambitious to ignore dangerous performances of the people behind the Iron Curtain. M/R, however, gives the impression that your people keep their eyes open and that there are men to strain their brains and financial resources in order to keep and come abreast and to overtake THEM.

E. Jaeger, ing. diplômé

Weiningen ZH
Switzerland

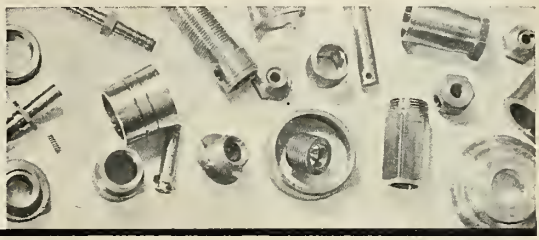
Objection Overruled

To the Editor:

In the news item concerning the scientists' protest against secrecy (June 22, p. 39), M/R used the phrase "consensus of opinion." This is incorrect English; correct usage is "consensus of 17 Nobel . . .," or "opinion of 17 Nobel . . ."

E. St. Thomas
Patrick AFB, Fla.

Webster says "consensus of opinion," while still objectionable to some, is now generally considered to be correct usage.



RECYCLING REFERENCE

To the Editor:

Your article on space feeding (June 15) seemed to strike a chord but it has taken me some time to track down the quotation. With reference to the paragraph commencing "Water Recovery" I would suggest you read . . . II Kings, Chap. 18, Verse 27 . . .

HIGH PRESSURE HOSE FOR AIRCRAFT AND MISSILES

STRATOFLEX

SUPER "T-HP" Teflon* HOSE

with
medium pressure "SUPER-T" RELIABILITY

Withstands tests more severe than MIL-H-8788

- High Temperature Spectrum tests exceed MIL-H-8788 in both impulse and temperature requirements and fully qualified to ARP 604.
- Positive lock fitting through elimination of socket hex.
- Available with swivel elbows that can be rotated without disturbing the wire grip lock.
- Stratoflex High Pressure Fitting combines the exclusive Pressure Activated Gland Seal and the assurance of crimp design.
- Shelf life practically unlimited.
- Available in two styles of high temperature fittings. Combination of stainless steel and carbon steel, or corrosion resistant all stainless steel fittings.

Hose assemblies are factory assembled from stock with straight, 45° and 90° fittings. Other angles or connections are made to your specifications. WRITE FOR BULLETIN S-7 TODAY!

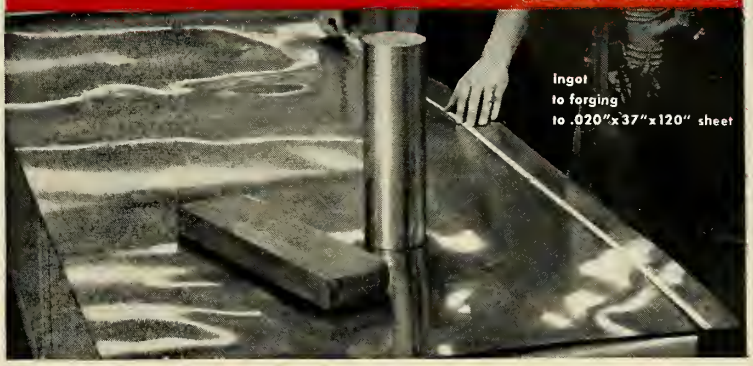
New Contracts to Push Thermoelectric Research

WASHINGTON—Contracts totalling over $1 million for continuing research work in thermoelectricity were awarded during the last quarter of FY '59 by Navy Bureau of Ships, coordinator for the armed services program in this field.

About half this amount is for two five-kilowatt generators. The balance is for development of new semiconductor materials and high-temperature research. A number of additional contracts are expected to be awarded this month after the beginning of FY '60.

New contracts listed include the following:



- Naval Engineering Experiment Station, Annapolis—$25,000/year
- Naval Boiler and Turbine Laboratory—$50,000/year
- **RCA** (Laboratories Division, Princeton)—$147,000
- RCA (Sarnoff Research Center)—$77,000
- **National Carbon Company**—$240,000
- University of Pittsburgh—$17,000
- **Carrier Corporation**—$194,000
- **Westinghouse Electric**—$342,475

Earlier efforts in this field, under the supervision of BuShips, have already produced significant results (M/R, 22 June). Most of these efforts have been in the so-called Areas B and C—the temperature range below 1500°K. For useful applications in missile and satellite auxiliary power, however, which require radiation cooling of the cold junction, this range must be extended up to the 2000°K mark. At higher temperatures the common semiconductors used in the successful work to date cannot be used: they melt, become bipolar-conductive, or oxidize. Thus, progress apparently depends upon finding new and better materials.

As mentioned, the highest temperature requirements are in the radiation-cooled systems. Here, fortunately, power per pound is more important than efficiency and very low thermal conductivity is not desirable. According to calculations, a space vehicle generator operating at an acceptable two percent efficiency could deliver a 10-amp current and would weigh somewhere between 45 and 208 pounds per kilowatt.

Considerable work is also being done on the reverse of thermoelectric power generation: Peltier cooling. Applications have already been made in infrared detector cooling and a wide field of electronic temperature control is being explored.

2 MORE FANSTEEL SPACE-AGE ALLOYS with High Strength-To-Weight at HIGH TEMPERATURES

FANSTEEL 80 METAL

Alloy—Columbium-zirconium

Melting Point—4350°F.

Density—
8.6 groms per cc (0.311 lb. per cu. in.)

Tensile Strength—
Anneoled 70°F.; 47,000 psi.

Stress-To-Rupture—
100 hr. 2000°F.
(argon) 18,800 psi.
500 hr. 2000°F.
(argon) 11,000 psi.

Other Praperties—Ductile to brittle transition temperotures in anneoled state are well below room temperoture.

Advantages ond Uses—Extremely high strength-to-weight ratia for high temperoture opplications. Excellent weldability, ductile welds with little or no tendency to frocture in heot affected zones. Easy fabricotion at raom temperature, os warked or annealed. For missiles, rockets, spocecroft, other high heat applicatians.

FANSTEEL 82 METAL

Allay—Columbium-tantalum-zirconium

Melting Point—4550°F.

Density—
10.26 groms per cc (0.371 lb. per cu. in.)

Tensile Strength—
Anneoled 70°F.; 55,000 psi.
2000°F. in oir; 29,600 psi.
2400°F. in air; 11,700 psi.

Stress-Ta-Rupture—
100 hr. 2000°F. (orgon) 17,500 psi.
500 hr. 2000°F. (argon) 13,500 psi.

Other Properties—High oxidation resistonce compared to pure refroctory metols. Oxide film is tenacious, non-volotile, tends to form protective caoting. 16-hour, 2000°F. tests in flowing oir show remarkobly law scaling of 0.01 cm.

Advontoges ond Uses—Exceptionally suitable for oir-frames ond certain missile opplications. Provides desirable strength-to-weight odvantages ot higher temperatures plus the same workability, weldobility ond ductility of Fansteel 80 Alloy.

AVAILABLE in ingots, forgings, bor, rod, plate, sheet ond fobricated ports.
Write for lotest technicol bulletins.

BUILT TO MIL SPECS...

one Brush Monitor records 100 countdown operations simultaneously!

Built to military specifications and performing to extremely rigorous military requirements, the Brush Operations Monitor can prevent aborts and destructs costing millions of dollars.

For quick, accurate and immediately visible go and no-go information, 100 operations are recorded simultaneously on a 500′ moving chart only 12″ wide. You have an *immediate* picture of an entire situation with each event shown in a time relationship to all other events. It is now being used for major check-out of propulsion systems, electrical test racks, fault isolation programmers and launch control vehicles.

Brush is now in production on this Mil Operations Monitor and prompt delivery can be made to your requirements. Phone or wire Brush for complete information and application assistance.

BRONZE POWDERS FOR FINER FILTERS

The critical operating conditions of today's jet aircraft and missiles could not be met without the dependable, ultrafine filtration of fuels, propellants, lubricating and hydraulic fluids provided by modern, porous metal filters.

These porous metal filters—fabricated from MD bronze powders that meet the most exacting physical and metallurgical requirements—may well be the answer to your own fine filtration problems. MD makes only the filter powder, not complete filters, but we will be glad to send you a comprehensive list of filter fabricators.

ALUMINUM POWDERS OF CONTROLLED PARTICLE SIZE

Aluminum powders of controlled particle size also play an essential role in the missile and rocket program. MD has 44 years of experience in producing these powders. We will welcome the opportunity to discuss your requirements.

OTHER METAL POWDERS AVAILABLE FROM MD ARE

ANTIMONY • BISMUTH • CADMIUM
COPPER • IRON OXIDE • LEAD • MANGANESE
NICKEL • SOLDER • TIN • TITANIUM • ZINC

Remember—for metal powders your best source is Metals Disintegrating Company, world's largest manufacturer of finely divided metals.

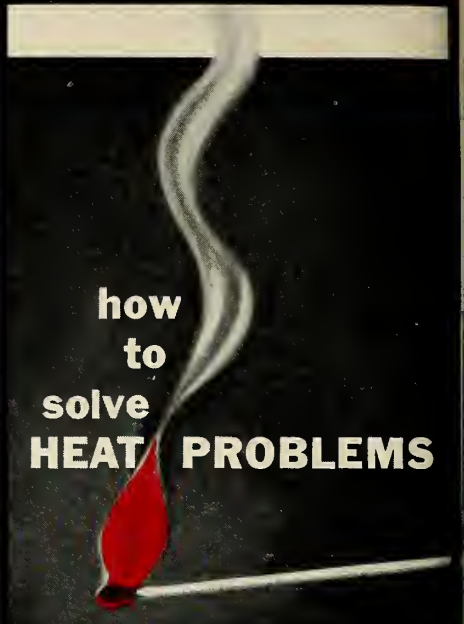
FIREBEE···THE HIT OF PROJECT WILLIAM TELL



"I'll never want to fire at towed targets again!"

That's the typical reaction of Air Force interceptor pilots after they fired at Ryan Firebee jet targets during the recent "Project William Tell" Weapons Meet.

78 Firebees, launched off the Florida coast, brought combat realism to the 10-day meet. Acting as "enemy" jet bombers, the free-flying Firebees streaked in at over 500 mph, from 14,000 to 42,000 feet, and flew an average of 31 minutes each.

Air Force pilots and weapons systems crews met this realistic test with the most impressive teamwork and skill ever displayed at a weapons meet.

Fastest way to solve space age heat problems of aircraft and missiles is to put Ryan to work for you.

Ryan has spent 20 years in applying advanced metallurgy to production techniques with 35 high-temperature alloys ...has fabricated them into critical hot parts for many major power plants...has put them into volume production.

Ryan hot parts are giving outstanding service in turbo-jets, afterburners, prop-jets, ramjets, rockets, and piston engines. That's why Ryan has the answers to high-temperature problems—from hot parts to complete engine packages.

Sharp new eye for navigation

Six major types of Navy aircraft will be equipped with Ryan continuous-wave Doppler navigation systems under an initial $20-million contract awarded by the Navy to Ryan's Electronics Division.

Developed in cooperation with the Navy, these advanced electronic systems are the lightest, simplest, most compact, most reliable of their type.

This new order, one of the largest of its kind, further emphasizes Ryan's leadership in electronic navigation and guidance systems.

Ryan offers outstanding challenges to engineers

ATLAS *U.S. AIR FORCE Surface-to-Surface*

The first United States intercontinental ballistic missile, *Atlas* is going through the final stages of its development and is rated by the Air Force as having "initial operational capability." Missiles are being delivered to the first operational user, the 576th Strategic Missile Squadron at Vandenberg Air Force Base, Calif.

Also known as *WS-107* and *SM-65*, *Atlas* has been fired about 30 times since its first flight in June, 1957, with varying degrees of success. A full-range flight of more than 6300 statute miles was made in November, 1958. The following month, an *Atlas* was launched into orbit as part of the USAF's space research program.

Designed to impact a target more than 5500 nautical miles distant with an error of less than two-tenths of one per cent, *Atlas* is guided over approximately the first 10% of its flight. Three liquid-propelled rocket engines generate launch power. The two boosters drop away after about two minutes blast output and the missile continues on the power supplied by its lower thrust sustainer. Two verniers located on the lower portion of the body supply roll control and thrust adjustment throughout second-stage flight.

SPECIFICATIONS

DESIGNATION: SM-65 (WS-107A-1)
PRIME CONTRACTOR: Convair (Astronautics) Div. General Dynamics Corp.
STATUS: Development and initial operation
RANGE: 5500 nautical miles plus
VELOCITY: 17,000 mph
FRAME
- Stages: 2
- Manufacturer: Convair
- Length (Overall), ft: 81
- Diameter (Body), ft: 10
- Weight (Gross), lb: 260,000
- Material (Major): Steel

GUIDANCE
- Manufacturer: GE/Burroughs; Arma
- Type: Radar-Doppler Command (later models all-inertial)

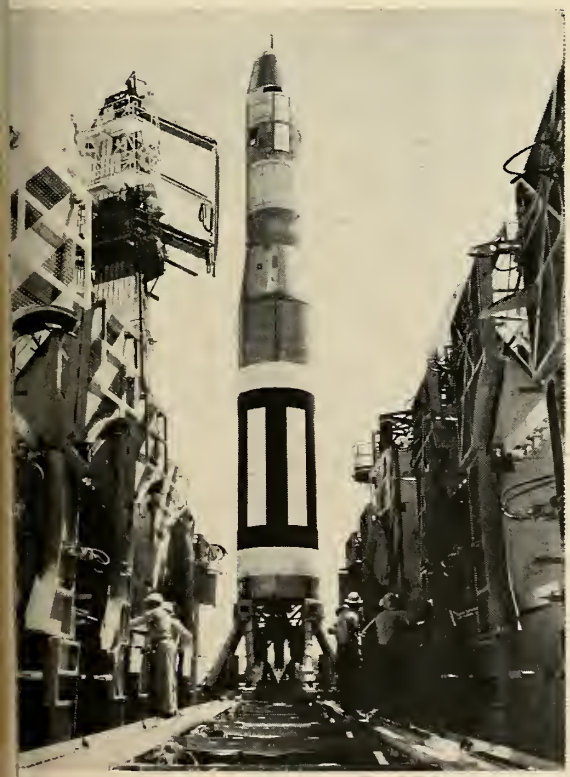
POWERPLANTS
- First Stage (Booster)
  - Manufacturer: Rocketdyne
  - Propellants: Liquid oxygen and kerosene
  - Type & Number: Regenerative liquid (2)
  - Thrust, lb: 150,000 each
- Second Stage
  - Manufacturer: Rocketdyne
  - Propellants: Liquid oxygen and kerosene
  - Type & Number: Regenerative liquid (1)
  - Thrust, lb: 60,000

WARHEAD
- Type: Nuclear

GROUND SUPPORT MAJOR CONTRACTORS
- Launcher: Consolidated Western Steel, National Steel
- Fueling: AiResearch Mfg. Co., Reaction Motors
- Radar & Ground Control: Norden, A Div. of United Aircraft
- Handling & Services: Goodyear Aircraft
- Transport Vehicles: Goodyear Aircraft
- Checkout Equipment: Radio Corporation of America, Consolidated Systems Corporation, Minneapolis-Honeywell

*LAUNCHING of *Atlas 10B* sent into orbit on Dec. 18, 1958, largest U.S. satellite

TITAN *U.S. AIR FORCE Surface-to-Surface*



The second part of the USAF's *WS-107* intercontinental ballistic missile project, the *SM-68 Titan* made its first test flight on Feb. 6, 1959, at the Atlantic Missile Test Range and has had several tests since.

A complement, rather than a duplicate of *Atlas, Titan* employs a different flight technique than its companion ICBM. A two-stage missile, it is launched initially by a 300,000-pound-thrust booster. At burnout, the first stage separates from the remainder of the missile and a second liquid engine pushes the nuclear payload to high speed and altitude. The second stage also drops after burnout and the nose cone coasts the rest of the way in a free-fall path without power or guidance.

Titan, though larger than *Atlas,* is also lighter. It will be based in "hard sites," with underground silos providing protection from weather during storage period and from blast effect in combat. Initial contract of $384,000,000 was awarded Martin for design, fabrication and testing.

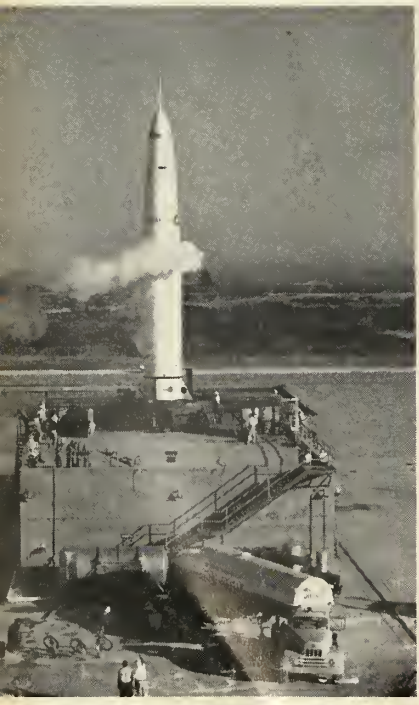
Transport vehicles:	North American

READY for static testing, *Titan* is framed by its erector.

HURTLING spaceward, a *Titan* passes first test at the Cape.



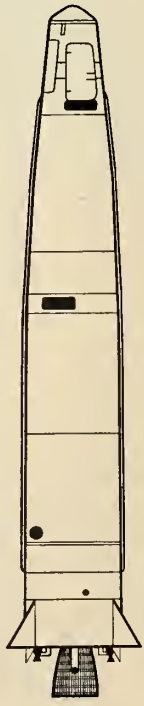
THOR *U.S. AIR FORCE Surface-to-Surface*

The first American intermediate range ballistic missile to achieve operational status, *Thor,* or *WS-315A,* was deployed to Europe in September, 1958, under an agreement whereby the United States furnished a number of the IRBM's to the United Kingdom.

Thor is a single-stage missile capable of being transported by air on a transporter-erector trailer which also serves as the missile erecting arm.

Thor has been used as the main propulsion system for several space experiments. It is the primary vehicle in the *Discoverer* program and was used to launch the lunar probe of Oct. 11, 1958.

Power is supplied by a Rocketdyne 150,000-plus-pounds-thrust engine which burns liquid oxygen and RP-1, a high-grade kerosene. Thrust adjustment and roll control are obtained by two vernier engines at the base of the missile; the sustainer is also provided with gimbaling action.



PREPARING for launch of versatile *Thor.*

TAKE-OFF with 150,000 lbs. thrust.

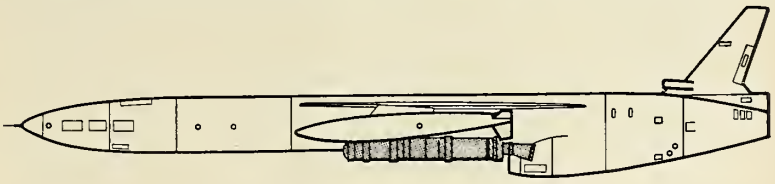
SNARK *U.S. AIR FORCE Surface-to-Surface*

A complementary weapon to the ir Force's long range ballistic mis- les, the *SM-62 Snark* is an intercontinental missile of the air-breathing variety, particularly useful in tactical pplications which call for low-altitude rget penetration. It is boosted by a air of solid rockets and sustained in ght by a turbojet engine.



Similar in appearance to a jet ghter, *Snark* has slim fuselage lines ith a high aspect ratio wing mounted ear the top and slightly forward of e center of the fuselage.

For economy in test operations, the '-foot, 30-ton missile is fitted with re- ctable gear to allow landing after st flight.

In the last year, *Snark* has been ed successfully 5000 miles down e Atlantic Missile Range. On one ght, it was fired 1300 miles and turned to land at the launching site. he first production model made a 000-mile test flight on April 7, 1959.

T-TESTED *Snark* **shown awaiting another trial at Patrick AFB, where it has been launched and successfully returned.**

SKY-BOUND *Mace* with flaming booster.

MACE *U.S. AIR FORCE Surface-to-Surface*

Designed to replace *Matador*, the *TM-76 Mace* became an operational weapon in 1959 and was deployed to Germany in the spring with the 38th Tactical Missile Wing.

Mace uses either an inertial guidance system or ATRAN, a map-matching system, depending on its mission. The ATRAN version is *TM-76A*, the inertial *Mace TM-76B*.

A relatively low-cost missile, it ru about $250,000 including Governmen furnished engine, booster and guidan package. *Mace* was first fired in 19 and placed in production in 1958.

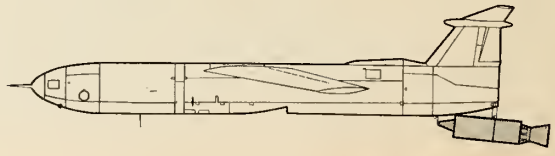
MATADOR *U.S. AIR FORCE Surface-to-Surface*



In operational service in Germany since March 9, 1954, *Matador* was the first USAF missile to attain service status. Controlled electronically by ground personnel, *Matador* carries either conventional or nuclear bomb-load. Based in Taiwan and Korea well as in Germany, *Matador* uni will be re-equipped with *Mace*.

STAND-BY *Matador* is being replaced.

BOMARC *U.S. AIR FORCE Surface-to-Air*

A supersonic pilotless interceptor, ıe *IM-99 Bomarc* is an intermediate ıngе air defense weapon designed to ttack enemy bomber formations be- ɔre they reach target areas. It was de- gned to be complementary to, rather ıan competitive with, point defense issiles such as the Army's *Nike*.

Bomarc is launched vertically from ı automatically opening launcher- ıelter. Initial power is supplied by a booster rocket; at high speed, two ramjet engines take over for cruise power.

Latest version of the *Bomarc* is the "B" model, with double the previous range and nuclear warhead capability. The "B" employs a Thiokol solid rocket for boost power, instead of the Aerojet liquid booster in the original version. Speed and altitude capability of the "B" model is also greater than the predecessor version.

Boeing, manufacturer of the *Bomarc*, is operating a *Bomarc* training school at Harbor Island in Seattle, and the USAF is setting up another at Chanute AFB, Ill. A total of 16 *Bomarc* sites had been announced prior to 1959 Congressional hearings on the air defense master plan, which might cause revision in *Bomarc* plans. The first site, McGuire AFB, N.J., was scheduled to be operational by fall of 1959.

COMPLETED *Bomarc* **is lowered to the factory floor in Boeing's Seattle plant.**

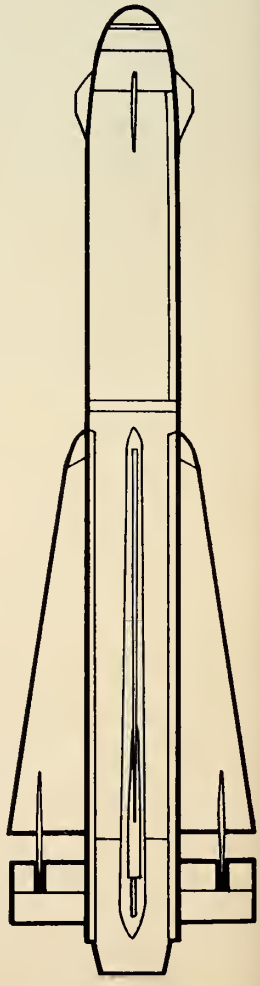
Transport vehicle: Burns & Roe, AMF

FALCON *U.S. AIR FORCE Air-to-Air*

Falcon is the name of a family of air-to-air missiles for use in conjunction with fighters of the Air Defense Command. Hughes Aircraft has produced five versions to date, the latest being the *GAR-3* and *GAR-4*. Previous versions included *GAR-1*, *GAR-1D* and *GAR-2A*.



GAR-1D and *GAR-2A*, smallest missiles in the USAF inventory, have been in operational service since 1956 on F-89, F-101 and F-106 aircraft. The *1D* version is radar guided, the *2A* guided by an infrared homing device. The interceptor planes can carry the *Falcons* in mixed loads, permitting selection of either type of guidance.

GAR-3 and *GAR-4* are improved versions of the two *Falcons* already in service. The *GAR-3*, scheduled for early operational service, employs a semi-active radar seeker type of guidance. *GAR-4* will have the infrared system, permitting the same "mix" as with earlier *Falcons*.

The *GAR-3 Super Falcon* features a new solid-propellant engine with greater burning time, providing increased range and speed. Principal external change is a longer and more pointed nose cone which adds several inches to the overall length. The new *Falcon* also has slightly increased wing span and the stabilizers have been extended so they reach beyond the center of the airframe.

Specifications below are for the basic *Falcon*, the *GAR-1D*. By comparison, the *GAR-3* measures 7.1 feet in length and has a wing span of two feet. It is being manufactured at Hughes' Tucson plant.

AT LEFT, *GAR-3*, soon to be operational. Right, *GAR-1D*.

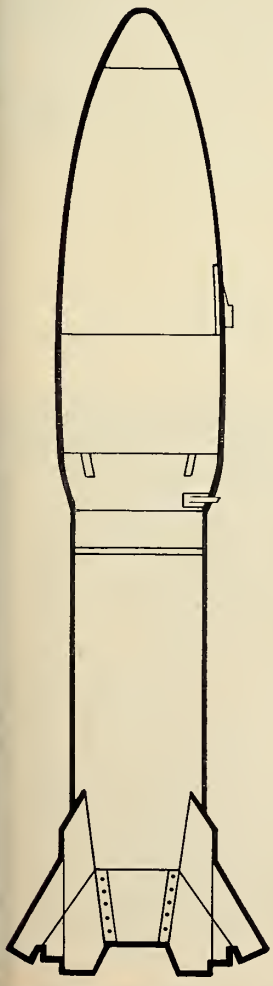
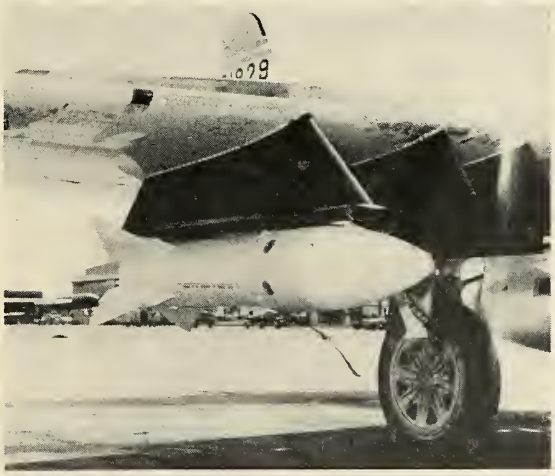
GENIE *U.S. AIR FORCE Air-to-Air*



An unguided rocket, the *MB-1 Genie* was the first air-to-air weapon to be equipped with a nuclear warhead. The nuclear head was developed by Los Alamos Scientific Laboratory.



Genie was first fired from an aircraft on July 19, 1957, during Operation *Plumbob* at the Atomic Energy Commission's Nevada test site. It was declared operational and added to the weapons inventory of Air Defense Command in January, 1958, and is part of the armament of F-89, F-101 and F-106 aircraft.

The relatively small missile is powered by an Aerojet-General solid-propellant rocket. An extensive testing program, continued after the weapon became operational, is nearing completion.

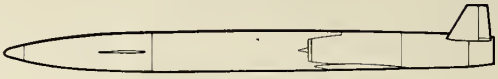
F-89 carries *Genie* under wing; F-101, F-106 use bay.

RELATIVELY small, the *Genie* nonetheless is equipped to deliver a nuclear wallop.



HOUND DOG *U.S. AIR FORCE Air-to-Surface*

TEST MODEL of *Hound Dog* attached to B-52, whose range it will soon be expanding.

Hound Dog is designed to extend the capability of Strategic Air Command's heavy bombers. Designated *GAM-77,* the missile will be able to deliver a nuclear payload on a target more than 500 miles from launch point. It is launched from a B-52.

GAM-77 is powered by a Pratt & Whitney J-52 turbojet, which can push the missile to supersonic speed. It was first tested on a limited range flight from the Atlantic Missile Range on April 23, 1959.

B-52 launches a *GAM-72 Quail,* designed to confuse the defenses of an enemy

U.S. AIR FORCE Missiles of the Future

ALBM

Following a series of feasibility studies with test vehicles, the Air Force decided to proceed with plans for an Air Launched Ballistic Missile. An important project, the missile is designed for use with B-52 and B-58 bombers, providing mobile aerial launch capability for missiles of 1000 nautical miles range or more. Initial concept called for a solid-fueled missile about half *Polaris* size. Douglas was awarded contract in June, 1959, calling for design, performance and cost study to be completed by year-end.

CROSSBOW

An adaptation of the drone aircraft to combat use, *Crossbow* is an air-to-surface missile designed to attack enemy defenses by homing on ground radar. To weigh about one ton, it will be subsonic with a range of about 200 miles. Power will be supplied by a small turbojet. Radioplane is prime contractor.

DYNA-SOAR

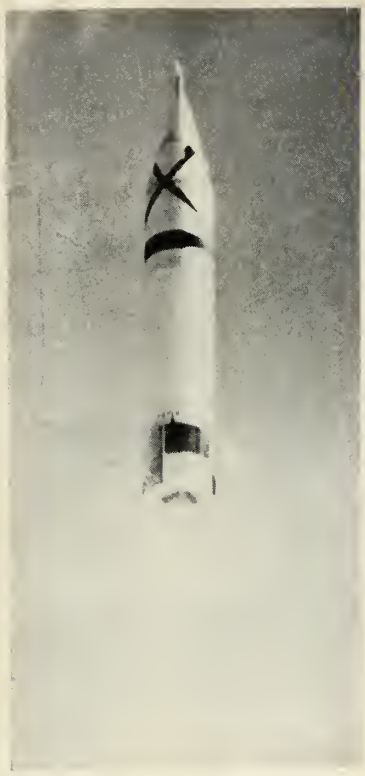
A combination of missile and manned airplane, *Dyna-Soar* is a hypersonic boost-glide bomber in early development stage. It will be boosted by high-thrust powerplants to near-orbital velocity at altitudes of about 100 miles, depending on mission. It has theoretical range of several earth circuits as reconnaissance vehicle, one circuit as bomber, coasting on its initial momentum with assist by small rocket sustainers. After intensive design studies involving a dozen companies, Boeing and Martin sought prime system responsibility.

GAR-9

An advanced version of the *Falcon* family of air-to-air missiles, *GAR-9* will combine the nuclear capability of *Genie* with the *Falcon's* accurate guidance. It is slated to become prime armament for North American Aviation's Mach 3 F-108 interceptor now in development status. North American and Hughes are collaborating on the system development; Aerojet-General will provide the powerplant.

MINUTEMAN

Operational requirements for a long-range missile with more rapid reaction time than the liquid-fueled ICBM's developed earlier brought about a contract, in 1958, for development of an all-solid ICBM, the *XSM-80 Minuteman*. With a maximum range of 5500 nautical miles, *Minuteman* will have greater flexibility in that it can be used for lesser ranges by dropping off one or more of its three stages. It will be a highly sophisticated weapon, incorporating the best developmental features from earlier ICBM experience.



Designed for operational use about 1963, *Minuteman* will be a "hard-based" missile, stored in underground bomb-proof silos ready for instantaneous action. First of the second generation long-range ballistic missiles, *Minuteman* will be smaller, lighter, less complex and considerably less expensive than its first generation counterparts. The program is under the management of ARDC's Ballistic Missile Division. In October, 1958, Boeing was named principal contractor for assembly and test.

WAGTAIL

An air-to-ground missile, *Wagtail* is designed for greater penetration effect through low-altitude launch. Concept calls for use of forward-firing rockets after launch and before ignition of primary power plant. This will permit very low velocities while guidance system adjusts to target. The sophisticated guidance system will then permit the weapon to climb over obstacles, like hills and trees, and attack at low level. Minneapolis-Honeywell is prime contractor for the *Wagtail* system.

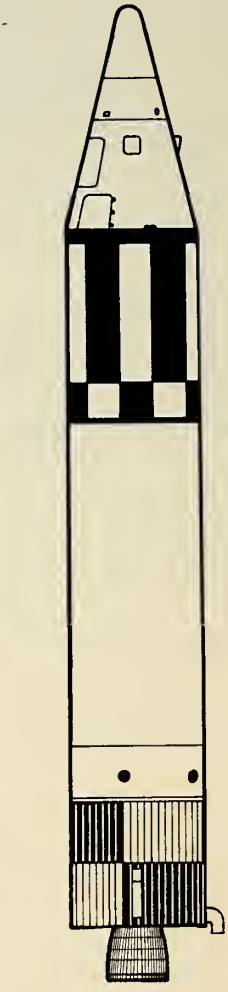
WHITE LANCE

Another air-to-ground weapon, designed for use with fighter bombers of Tactical Air Command, *White Lance* is an advanced version of the Navy's *Bullpup*. Martin is prime contractor. Initial deliveries to Air Force scheduled for near future, will include missiles almost identical to *Bullpup*. Later version will have increased range and be equipped with a greatly improved guidance system.

WORKHORSE *Jupiter* rises from Cape.

TWO-PART missile is field-assembled.

JUPITER *U.S. ARMY Surface-to-Surface*

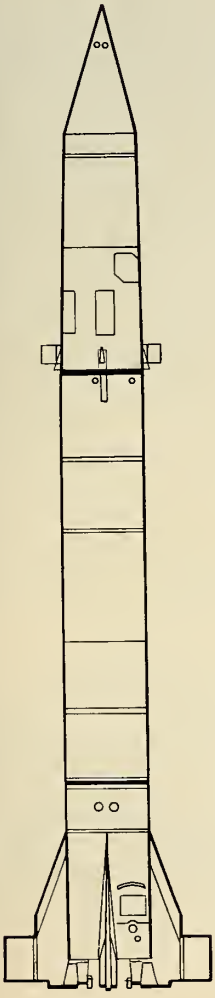


Developed by the Army Ballistic Missile Agency, the *SM-78 Jupiter* was the first American intermediate range ballistic missile to be launched successfully. In a Department of Defense decision on missile roles and missions, the *Jupiter* was turned over to the Air Force for operational employment, with training of USAF crews to be handled by ABMA.

The Air Force's 864th Jupiter squadron recently completed training at Redstone Arsenal, Huntsville, Ala. A second squadron, the 865th, is now in training there. The *Jupiter* system is scheduled to go to Italy this year.

Jupiter was designed to deliver a nuclear payload over a range of 1500 nautical miles. It is composed of two parts which are assembled in the field immediately prior to launchings. They are the "thrust unit," containing the rocket engine and fuel tanks, and the "warhead unit," which can contain either nuclear or conventional warheads and fuzing systems. Guidance is by the Delta Minimum self-contained all-inertial system of ABMA.

The *Jupiter* program was started in mid-1955 and first contract for engineering and production work was awarded Chrysler Corp. in June, 1956. *Jupiter* test vehicles have figured prominently in space research experiments including first recovery of a full-scale, heat-protected IRBM nose cone in May, 1958, and launching of a nose cone containing special instrumentation and a live monkey in addition to the warhead on Dec. 13, 1958.



First Chrysler-built, operational-type *Jupiter* was successfully launched on Jan. 22, 1959.

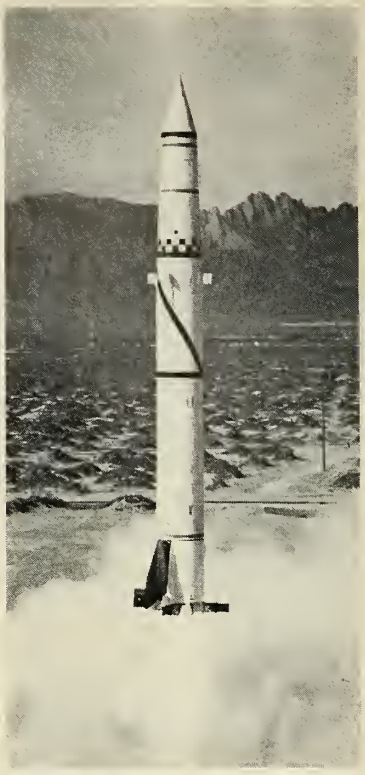
REDSTONE *U.S. ARMY Surface-to-Surface*

Developed by the Army Ballistic Missile Agency, the *Redstone* is a high-accuracy missile used to extend and supplement the range and fire power of artillery cannon. It is a mobile system which can be fired from portable launching pads. A well-trained unit can move into a previously surveyed position, fuel the missile, set the guidance and fire in about two hours.

Range of the weapon is 200 miles. Power is supplied by a 75,000-pound-thrust Rocketdyne liquid-propellant engine. Graphite vanes located in the exhaust of the rocket supply thrust control; and external fins provide aerodynamic stability. *Redstone* is cylindrical in shape with a conical nose and cruciform tail surfaces.



The missile's inertial guidance system is entirely self-contained. Prior to launch, the desired flight program is fed into a program device, which plays back the information to the various elements of the control system that guide the missile in flight.

The *Redstone* has nuclear capability, but it can also be armed with conventional explosives. The weapon is designed so that it may be transported by air, rail or truck, including the complete launching system. It is composed of three component parts which can be assembled in the field prior to launching: the powerplant unit, the fuel tank unit and the warhead and control unit. The missile is launched in the vertical position from a platform five feet high.

Redstone has been operational since early last year. Two Army Missile Groups *(Redstone)* are overseas.

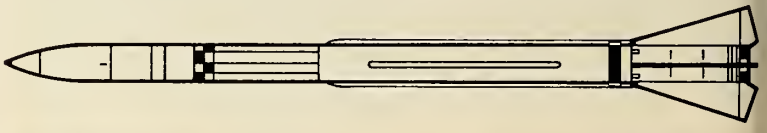
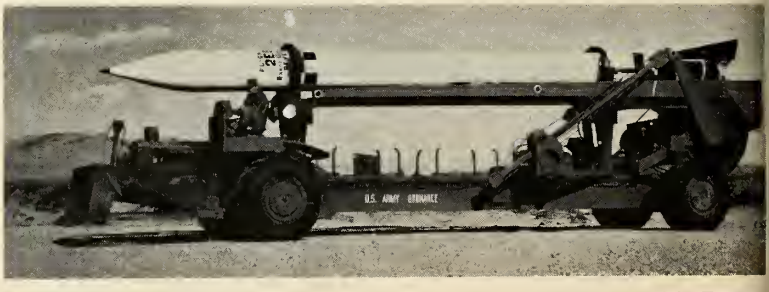
RELIABLE *Redstone* **is highly mobile.**

FIVE-FOOT platform is high enough.

CORPORAL *U.S. ARMY Surface-to-Surface*



SOARING up from White Sands range.



A 30-inch diameter Army artillery missile, *Corporal* was the Army's first ballistic-type weapon. It is in operational service and battalions have been deployed to Europe. A 75-mile-range missile, it is scheduled for replacement by the more advanced *Sergeant*.

The Corporal program has two prime contractors. Firestone Tire and Rubber Co.'s guided missile division has responsibility for production of the missile and for ground handling and launch equipment. Gilfillan Brothers, Inc., handles radar and other ground guidance equipment. Gilfillan also serves as subcontractor to Firestone for some of the guidance components in the missile.

Corporal is guided by a preset and command system. Basic firing data is computed for the guidance equipment and entered as "dial settings" before the missile is launched. After firing, minor corrections are made to the trajectory to insure accurate impact.

In service use, a *Corporal* battalion has 250 men. Each battalion has two batteries, a firing battery and a headquarters service battery. There are two operational launchers in each battalion. The *Corporal* carries either a conventional or nuclear warhead in the eight-foot nose section. Below lies the guidance stowage section, followed in sequence by a cluster of cells to carry compressed air to pressurize the propellant tanks, the propellant valve system, the rocket engine and the guidance vanes and rudders. The missile assembly measures 46 feet.

TACTICAL transporter-erector for *Corporal*. Battalions have been deployed in Europe.

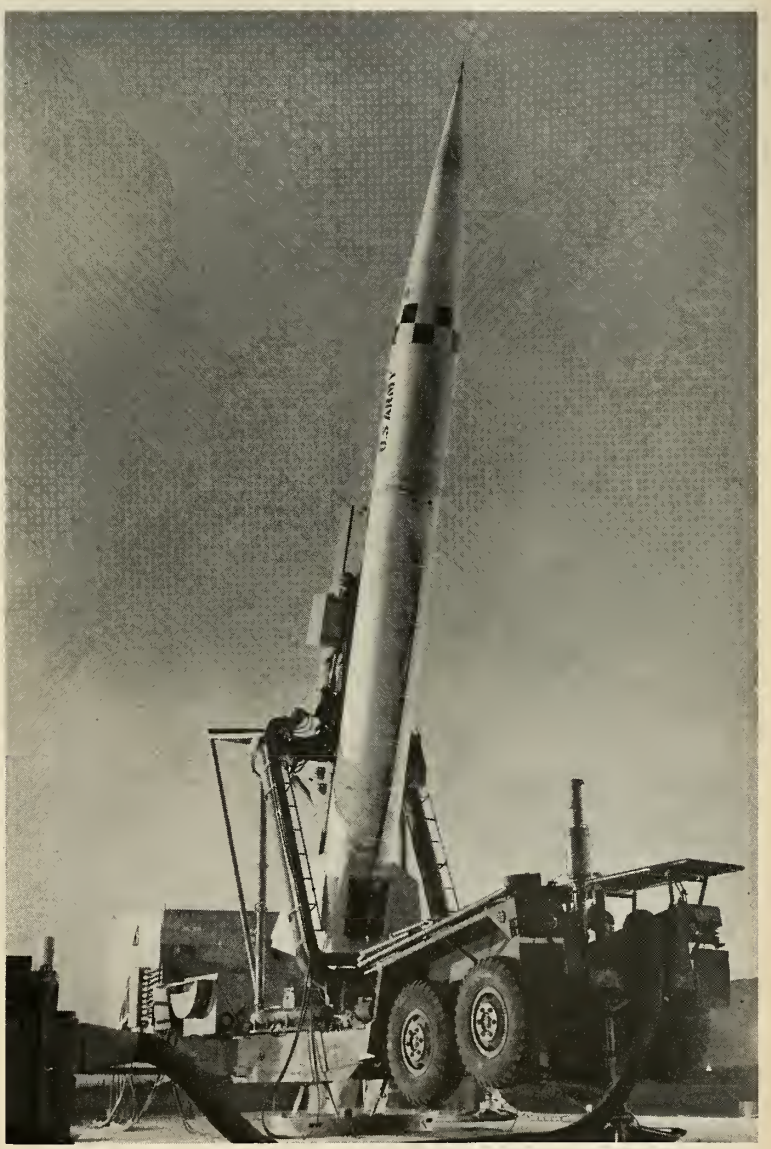
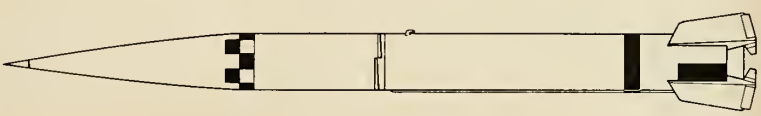
SERGEANT *U.S. ARMY Surface-to-Surface*

Sergeant is a solid-fueled ballistic-type battlefield missile designed to replace the six-year old *Corporal*. It incorporates many improvements over its predecessor in mobility, reliability and accuracy, although range is approximately the same.



Like *Corporal*, the *Sergeant* can carry either a nuclear or conventional warhead, is air transportable and can be rapidly emplaced and fired under all conditions of weather and terrain by a comparatively small crew. The use of solid propellants and inertial guidance have minimized system maintenance requirements and simplified ground handling procedures and equipment. The missile is launched in a near-verticle position from an erector-launcher.

Development of the *Sergeant* to its current state of refinement is the result of a joint effort between Jet Propulsion Laboratory and Sperry Utah Engineering Laboratory. Production of the weapon system, including erector-launcher, servicing, handling and maintenance equipment, is the responsibility of Sperry Rand Corporation. Sperry received the prime contract for production of the missile system in 1956.



The *Sergeant* is currently entering first hardware production at Sperry's Salt Lake City manufacturing facilities.

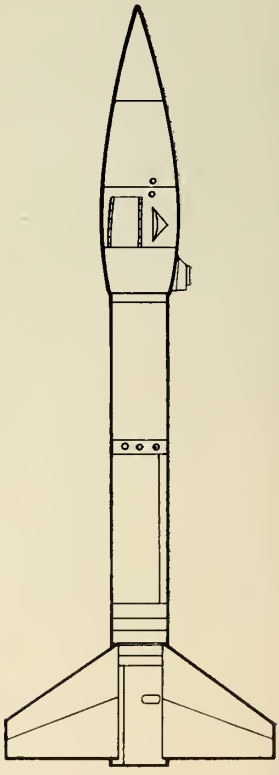
HONEST JOHN *U.S. ARMY Surface-to-Surface*

Originally developed by Army Ordnance, *Honest John* is an artillery rocket designed to provide close fire support for ground operations. It is mounted on and launched from a highly mobile self-propelled launcher.



Honest John, originally designated *M-30* but now known as *M-31A1C*, is a free-flight rocket having no electronic controls. It features extreme mobility and simplicity, and it can be fired by a crew of six. It can carry a variety of warheads, including conventional high-explosives, nuclear or chemical loads. Its range is equivalent to that of medium-to-long range artillery.

Major parts of the *Honest John* rocket—the head compartment, fins, pedestal and power plant—are assembled at the factory or arsenal. Final assembly takes place near the firing site, and the completed rocket is then moved forward to the battle zone on its self-propelled launcher.

Honest John has been under development since 1950 when Army Ordnance first outlined to Douglas Aircraft Co. the basic idea for a large calibre artillery rocket. First tests, conducted at White Sands in 1951, dictated a series of improvements. Further tests with modified rockets led to large-scale contracts.

SIX-MAN crew can handle and fire *Honest John*, shown on its self-propelled launcher.

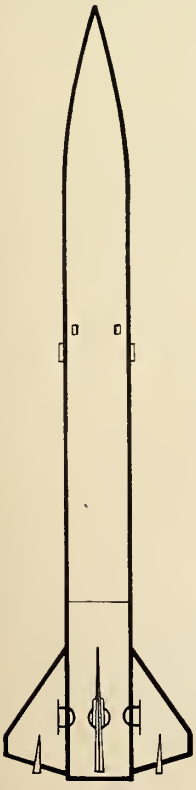
LITTLE JOHN *U.S. ARMY Surface-to-Surface*

Designed and developed by the Army's Redstone Arsenal as a supplement to *Honest John*, the *XM-47 Little John* is also a free-flight rocket without electronic controls, featuring a high degree of accuracy, simplicity of design and ease of operation. Its range is comparable to that of medium and heavy artillery.

Little John is about half as long as *Honest John*, has a body diameter of only 12½ inches compared with 30 for *Honest John*, and weighs only 800 pounds, less than a sixth as much as its companion weapon. Lightweight launchers and ground equipment are adaptable for an extremely high degree of mobility on the ground. They can also be airlifted by either fixed-wing aircraft or helicopters.



Although not yet officially designated operational, *Little John* rockets were turned over this year to the 101st Airborne Division, Fort Campbell, Ky., for training and development of combat techniques.

Little John was developed under a "crash" program that started at Redstone Arsenal in February, 1956. It was first test fired in June of that year.

Propellant for the solid-fueled rocket is produced by Allegheny Ballistics Laboratory, with Consolidated Western Steel supplying motor parts. Frame is built by Emerson Electric and the Army's Rock Island Arsenal provides the small, compact launchers.

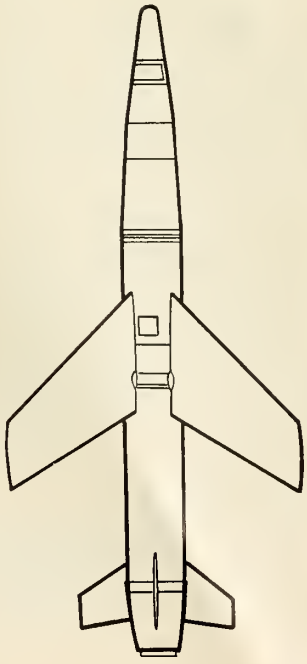
LACROSSE *U.S. ARMY Surface-to-Surface*

Developed out of the experiences of the Pacific campaigns of World War II, where it was difficult to get artillery hits on targets like caves and bunker entrances, *Lacrosse* is designed to replace heavy artillery in strikes against strong points delaying advance of ground troops.

A highly accurate weapon, *Lacrosse* has its own missile automatic checker which automatically tests all phases of its operation just before firing. The *Lacrosse* system consists of the missile, a launcher mounted on a standard two-and-one-half-ton truck, and the guidance system, which is controlled by a forward guidance station acting in a capacity similar to a field artillery observation post. Like *Honest John* and *Little John, Lacrosse* features extreme mobility.

Lacrosse weighs slightly more than a ton and can carry a wide variety of conventional or atomic warheads, depending upon the tactical situation. The missile body has three major assemblies: nose section, center and tail. Fo swept wings and four movable tail fi control pitch, yaw and roll.



The first two units employing *L crosse* were activated in June, 195 They are the 5th Missile Battalio 41st Artillery, and the 5th Missile Ba talion, 42nd Artillery, both located Fort Sill, Okla. Each has approximate 170 officers and enlisted men. The mi sile was developed by Cornell Aeronau tical Laboratory and put in productic by The Martin Co. at its Orlando plan

NIKE-AJAX

U.S. ARMY Surface-to-Air

Nike-Ajax, the first American surface-to-air operational missile, has now been phased out of production and will gradually be replaced by *Nike-Hercules* units, although it is still operational in a number of metropolitan sites. Still capable of combating known types of bomber aircraft, it has been in service since 1953. About 10,000 *Nike-Ajax's* were built and about 3000 have been fired in the Army's various test and training programs during the past six years.

HORIZONTALLY positioned on launcher.

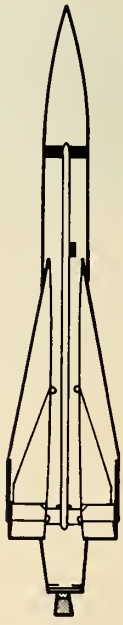
HAWK *U.S. ARMY Surface-to-Air*

One of the Army's newest air defense weapons, the *Hawk* is designed to be used primarily against low-flying enemy aircraft. It is a mobile system, to be used by both Army and Marine Corps troops in the field. Fired from a small two-wheel launcher, *Hawk* has a ceiling capability ranging from less than 100 feet to more than 38,000 feet. Unusual radar instrumentation provides effectiveness in the "blind zone" of conventional radars. The weapon system also has a high rate of fire, since three missiles can be fired from a single launcher.

Hawk is powered by a solid-propellant system developed by Thiokol and in production at Aerojet-Sacramento.

First *Hawk* emplacements will be located in New York and Washington to complement *Nike* defenses. A *Hawk* battery consists of 36 missiles, with three missiles to each of 12 launchers. The launcher emplacements are covered by balloon-like domes to protect the missile from the weather. The missile can be fired through the dome.



The *Hawk* system features simple, rugged equipment, easy to maintain. It is air transportable by helicopter or medium-sized fixed-wing aircraft. *Hawk* is scheduled to be operational in 1960.

THREE *Hawks* can be fired from one uni

VERSATILE ARMY *Hawk* sits poised for launching at the White Sands Proving Grounds.

U.S. ARMY MISSILES OF THE FUTURE

PERSHING

A selective range, surface-to-surface two-stage ballistic missile, *Pershing* is designed as eventual replacement for *Redstone*. Both stages will be solid-propelled, permitting ease of handling in the field. With a new transporter-erector-launcher, *Pershing* will have the mobility of the smaller missiles in the Army battlefield family. It will deliver a nuclear warhead up to 700 miles. *Pershing* will be smaller than *Redstone*—about 50 feet overall compared with *Redstone's* 63 feet—and considerably lighter than its predecessor.

Martin-Orlando has the prime system responsibility. Fuzing and arming subcontractor for the nuclear warhead is Bulova Watch Co. Bendix Eclipse-Pioneer is developing the inertial guidance stable platform and associated equipment. Thiokol will provide the solid-propellant rockets and Thompson Products Accessories Division is developing the new transporter-erector-launcher.

NIKE-ZEUS

An advanced air defense weapon, *Nike-Zeus* is being developed to provide a defense against all forms of air threat, with special emphasis on defense against ballistic missiles. A solid-propelled weapon, it will have a nuclear warhead and a command guidance system. *Zeus* will be about the same length as *Nike-Hercules*, but considerably heavier. A high thrust powerplant of 450,000 pounds thrust will boost it to Mach 7 speed. Range will be about 200 miles.

Prime contractor is Western Electric, with Douglas building the frame. Thiokol will build the large booster and Grand Central the sustainer rocket.

SS-10, SS-11

Already in production, the *SS-10* and *SS-11* are anti-tank guided missiles. They are wire-guided and employ solid propellants. They can be launched from a fixed emplacement, from a ground vehicle, a helicopter or an airplane. *SS-11* is an advanced version of *SS-10*, having twice the range and higher speed. Both weapons are built by Nord Aviation in France and are being procured in service and evaluation quantities.

SHILLELAGH

A lightweight missile system being developed for close-in support of ground troops, *Shillelagh* is designed to provide "greatly increased firepower," probably nuclear, against armor, troops and fortifications. In one application it will be vehicle-mounted. Expected to be operational in the mid-1960's, its prime contractor is Aeronutronics Division of Ford Motor Co. (The system is also known as *Pentomic*.)

REDEYE

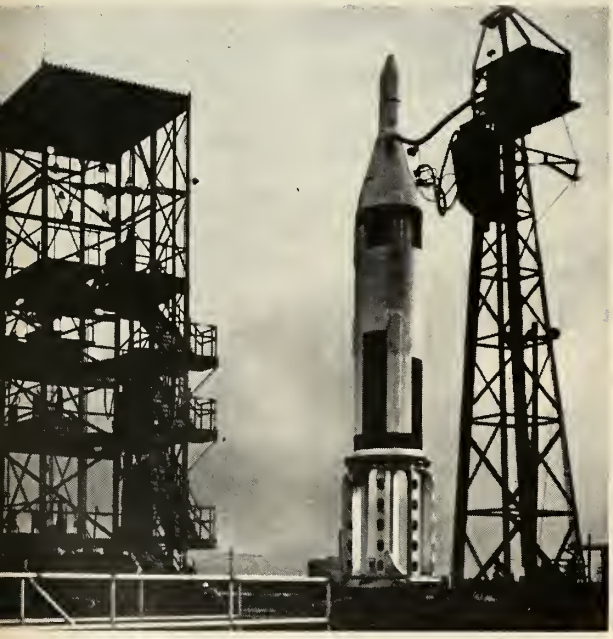
A shoulder-fired, bazooka-type air defense missile, *Redeye* is designed to provide individual troops with defense against low-level air attack in forward areas. Marine Corps is also interested in the development program. Guidance will be infrared homing. Prime contractor is Convair-Pomona.

DAVY CROCKETT

Another weapon for the pentomic Army, *Davy Crockett* is a light, nuclear-tipped weapon designed to be fired by one or two men in the field. It is being developed as a family. Prime contractor is Martin.

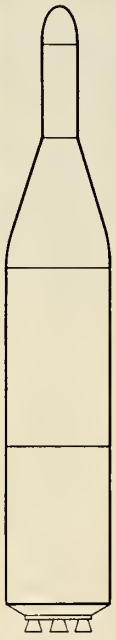
LOBBER

Not a weapon but a cargo ballistic missile, *Lobber* is a nine-foot solid-propellant ballistic missile designed to carry a 50-pound payload over a 50-mile range. Fired from a portable launcher, it was first tested last December. Basic idea is to move priority equipment such as medical supplies in the battlefield area. *Lobber* is first step in a program to study feasibility of moving much larger priority payloads, ultimately including men. Convair has been awarded a *Lobber* development contract by the Army.



POLARIS *U.S. NAVY Surface-to-Surface*

One of the most important missiles in the American arsenal, *Polaris* adds a new dimension to naval warfare in the atomic age. Launched from mobile, underwater bases it has range equivalent to land-based intermediate range ballistic missiles. The Navy calls it an FBM (Fleet Ballistic Missile).



Of advanced design, *Polaris* is considerably smaller and lighter than its land-based counterparts. A single FBM submarine, specifically designed for the *Polaris* system, can carry 16 missiles. Missiles are carried aboard the sub in individual containers. At launch time, inert gases propel the missile above the water. Its rocket booster then takes over to provide initial boost. At altitude, a second-stage rocket cuts in to put the weapon on its ballistic trajectory toward target. Guidance is inertial, and both rocket stages are solid.

Tied in with the *Polaris* system is the Ship Inertial Navigation System (SINS) developed by Sperry, which provides at any given time the latitude, longitude, local vertical and precision azimuth.

Although designed primarily for use with the new FBM subs, *Polaris* can be launched from surface ships equipped with SINS or from land installations. Under present shipbuilding programs, nine *Polaris* FBM subs have been authorized; six of them are under construction. The *Polaris* system is scheduled for operational use late in 1960.

NAVY'S *POLARIS* should be ready for operational use next year.

BLAST OFF—Test vehicle leaves Cape.

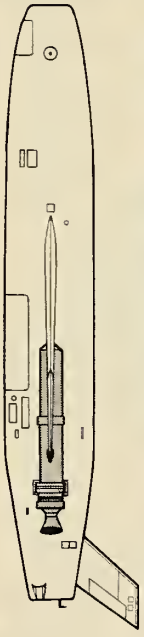
REGULUS *U.S. NAVY Surface-to-Surface*

Regulus I, the first operational attack missile to join the fleet, resembles a swept-wing jet fighter. Under development since 1948, it achieved operational status in 1954. Currently, four conventional submarines and four cruisers have *Regulus* capability. The missile was phased out of production in 1958, but is expected to remain on operational duty for some time. A total of 514 of the missiles were built by Chance Vought.

The 900th launch of the recoverable missile was accomplished in April. 1959, from the cruiser USS Toledo.



Also in 1959, *Regulus* participated in Post Office Department experiments in carrying "missile mail." One *"Reg"* carried mail on a training operation out of Point Mugu, Calif., in May. In June, a mail launch was effected from a submarine far at sea to the naval base at Mayport, Fla.

Regulus I is launched from a short rail launcher, where it rests on four slipper fittings. Launching boost is from two rockets which accelerate it to flying speed in about two seconds, when its turbojet sustainer takes over.

Regulus II, an inertially guided successor to *Regulus I,* with considerably greater speed and range, was cancelled by the Navy in December, 1958, after the missile had completed 90% of its development program. It had made 48 test launches, including launches from both a submarine and a surface ship.

REGULUS—with umbilical cord attached.

WHEELED CART is used to move *Regulus* on carrier deck.

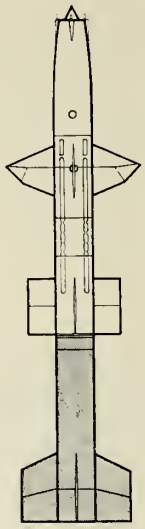
WEAPON ABLE

U.S. NAVY Surface-to-Surface

A 500-pound, 12.75-inch antisubmarine rocket, *Weapon Able* is installed on destroyers and frigates. A special fire control system aims the weapon, which carries a conventional explosive charge, at enemy subs; it is unguided in flight. The rocket sinks rapidly and covers a larger ocean area than old-type depth charges. It is in operational service.



TALOS *U.S. NAVY Surface-to-Air*

Designed originally as an air defense missile to protect the surface fleet from attacking enemy aircraft, *Talos* has indicated in testing that it can also be used as a bombardment weapon against ships or shore targets, or as a long range anti-submarine weapon when equipped with a nuclear warhead.

Talos recently became operational as the principal armament of the guided missile ship USS Galveston. It was first fired at sea from the Galveston on Feb. 25, 1959. Under the present shipbuilding program, seven cruisers, one of which will be nuclear-powered, will have *Talos* capability.

The missile is accelerated to high speed by a solid-propellant rocket. The booster is jettisoned upon attainment of cruising speed, and a 40,000 pound-thrust ramjet provides cruise power. The weapon carries a conventional high explosive charge with proximity fuzing. Employing beam rider guidance, it can reach targets at a range of 65 miles and altitudes above 75,000 feet.

Talos stemmed from the Navy's *Bumblebee* program and was originally developed by the Applied Physics Laboratory of Johns Hopkins University. The system was turned over to Bendix for production. A land-based Army version of *Talos* has been cancelled.

USS Galveston, first ship to be equipped with *Talos*, shows off its lethal weapon.

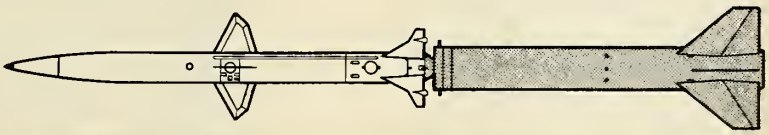
TERRIER *U.S. NAVY Surface-to-Air*

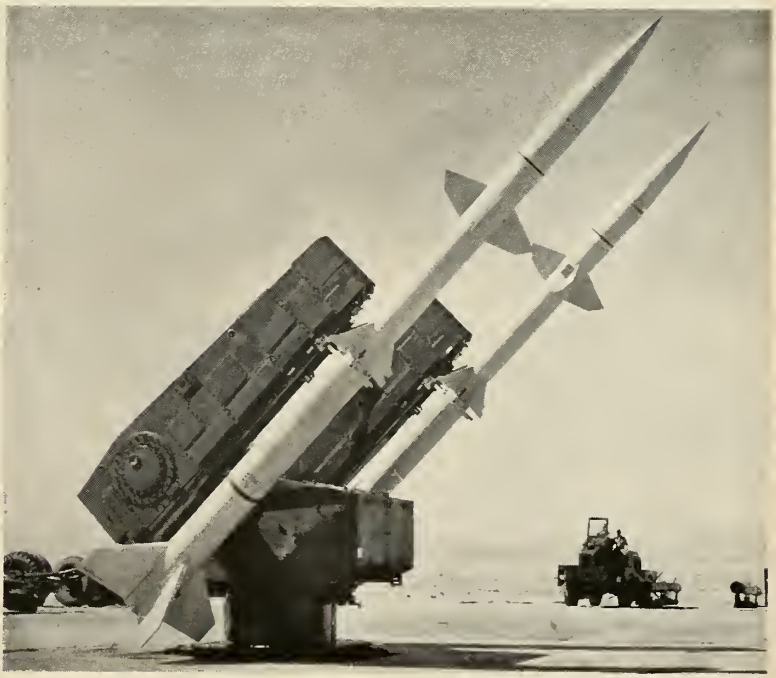
Another offshoot of the Navy's *Bumblebee* program, *Terrier* was designed to intercept enemy aircraft at ranges and altitudes beyond the capability of conventional anti-aircraft guns.

Terrier has been operational for five years and it is currently installed on the guided missile cruisers USS Boston and USS Canberra, and on the guided missile destroyer USS Gyatt. Under present shipbuilding programs, 27 additional ships will have *Terrier* capability. These will include: two Forrestal-class carriers, three guided missile cruisers, 1 nuclear-powered guided missile cruiser, 19 guided missile frigates, one nuclear-powered guided missile frigate, and one nuclear-powered aircraft carrier.

Terrier is also suitable for beachhead operations by the Marine Corps. The First Medium Anti-aircraft Missile Battalion, which is stationed at the U.S. Marine Corps Base, Twenty-nine Palms, Calif., is equipped with the missiles.



Booster-launched, the weapon travels to the target by beam-radar guidance.



On shipboard installation each *Terrier* launcher is served by its own magazine and missile overhauling and servicing room. The missiles and their boosters are stored vertically in a ready service ring, one for each arm of the two-missile launcher. The missile is selected, positioned, loaded and placed on its launching rail in a matter of seconds.

Terrier was developed by the Applied Physics Laboratory of Johns Hopkins University, at Silver Spring, Md. Production is handled by Convair/Pomona, Calif., a division of General Dynamics Corporation.

ADVANCED TERRIER

Under development is an *Advanced Terrier* incorporating improved guidance and with substantial improvements in coverage. A larger weapon than the basic *Terrier*, it is expected to have about double the range. Convair is prime contractor. The new missile will eventually replace *Terrier*.

SIDEWINDER *U.S. NAVY Air-to-Air*

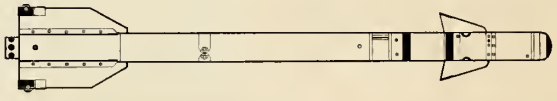
Sidewinder holds the distinction of being the first guided missile to destroy an aircraft under combat conditions. This occurred in September, 1958, when the weapon was used by planes of the Chinese Republic against Chinese Communist aircraft.

Sidewinder is a rugged, inexpensive missile with fewer than two dozen moving parts. Personnel require no specialized technical training to handle and assemble it.

The missile has a passive infrared guidance system which permits it to home on the tailpipe of the target aircraft. The seeker occupies the first four inches of the missile, followed by the guidance section. Servo motors are located between the forward fins. Warhead is high explosive.

Developed by the Naval Ordnance Test Station (NOTS), China Lake, Calif., *Sidewinder* became operational in July, 1956, and is now the guided missile most widely used by Navy squadrons with the Sixth Fleet in the Mediterranean and the Seventh Fleet in the Western Pacific. *Sidewinder* will also be used by the USAF and several allied nations.

SIDEWINDER 1-C



Under development at Naval Ordnance Test Station, China Lake, Calif., is a second-generation version of *Sidewinder*, known as *Sidewinder 1-C*, which will have higher speed and greater range capability. Philco Corp. is prime contractor with NOTS.

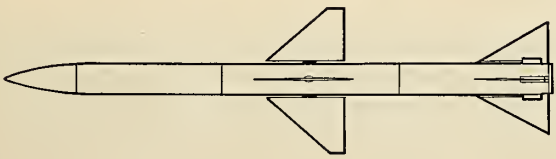
SPARROW III *U.S. NAVY Air-to-Air*

A fleet air defense weapon attaining a speed of 1000 miles per hour immediately after launching and a top speed of more than 1500 miles per hour, *Sparrow III* became operational in August, 1958. It replaced *Sparrow I*, phased out of production.



First deployment was with McDonnell F3H-2 squadrons in the Western Pacific. A new version with higher capability will be launched from the supersonic all-weather fighter, the F4H-1. The *Sparrow III* gave the fleet two features not available in earlier missiles of this type: all-weather capability and the ability to attack high-performance enemy aircraft from any direction, including head-on.

Guidance is by radar homing, which becomes active in the first seconds of flight by launching aircraft. Guidance signals deflect the wings of the missile and direct a collision course to the target, even under evasive action.

The now-obsolete *Sparrow I*, which became operational in the spring of 1956, was produced by Sperry-Farragut Co. *Sparrow II*, now cancelled, was an experimental weapon not intended for fleet use. Douglas Aircraft Corp. was prime contractor on *Sparrow II*.

ZUNI *U.S. NAVY Air-to-Surface*

IN FLIGHT, ***Zuni*** **clearly shows its blast-operated fins, which fold away and allow the rockets to be carried compactly.**

The Navy's *Zuni* was designed chiefly as a rocket for use by fighter and attack aircraft against ground targets. However, one of the four interchangeable warheads for the weapon permits it to be used against aircraft targets. The other three warheads are (1) general purpose, (2) antitank and antipersonnel, and (3) flare. *Zuni* has blast-operated folding fins, a feature that allows rockets to be carried compactly in expendable launchers each with four rounds. The rocket and its launchers were developed by the Naval Ordnance Test Station, China Lake, Calif., for the Bureau of Ordnance.

Zuni has been approved for operational use, but has not yet made its debut.

Zuni is effective against vehicle convoys, tanks, troop concentrations, gun emplacements, trains, and small ships. In night attack, one *Zuni* can illuminate two square miles of surface area with its flare head, while a second burst can deliver high-explosive warheads to destroy the target in the same pass by the attacking aircraft. Its high velocity and short time-to-target assures it a high-kill potential in air-to-air attacks as well.

Zuni, because it is an unguided weapon, has several advantages: immunity to countermeasures, all-weather capability, high reliability, and simplicity. Because of these advantages and because it does not require any field maintenance or checkout, it is especially well suited to sustained carrier operations in which aircraft complete a mission, land, refuel, rearm, and take off again.

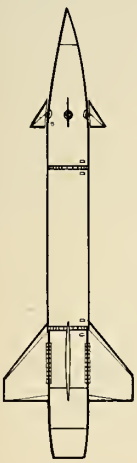
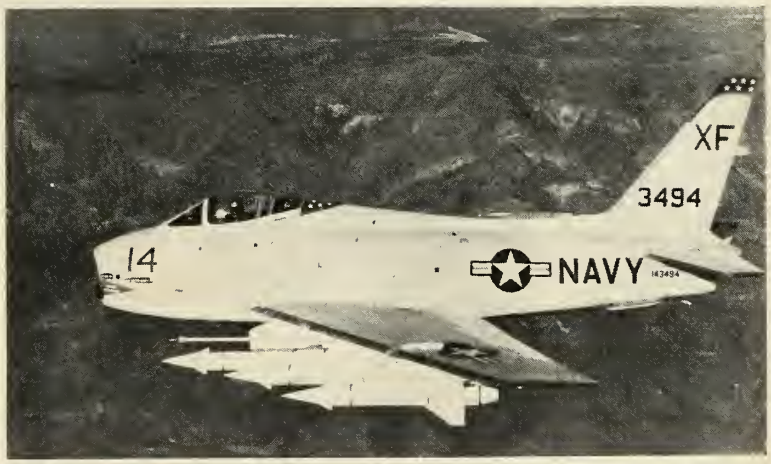
BULLPUP *U.S. NAVY Air-to-Surface*



Designed for air launching outside ne effective range of enemy fire, *Bull-up* provides light attack aircraft with reater capability against tactical sur-ace targets, such as tanks, airfield in-tallations, truck convoys, oil tanks and ailroads.

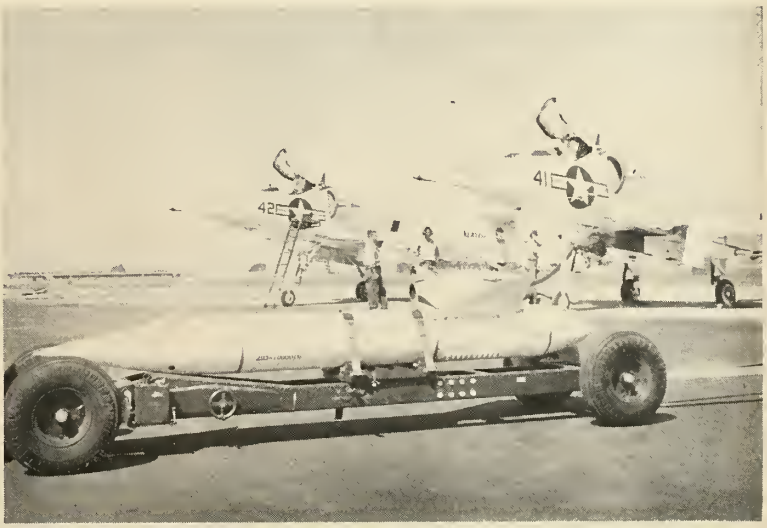


Relatively inexpensive, highly accu-ate and simple in design, *Bullpup* be-ame operational aboard the USS Lex-ington on April 25, 1959.

The weapon is guided by radio signal guidance under direct pilot control. Changes in direction are caused by pilot commands on a hand switch in the cockpit. These changes are transmitted to the missile where they are translated to movement of the control vanes.

The missile is divided into three major parts: the nose, containing the guidance control system; the center section, carrying a 250-pound warhead; and the tail, carrying propulsion and tracking flares. Power is supplied by a single solid rocket. The whole assembly weighs less than 600 pounds.

Bullpup is launched by several planes—the FJ-4B Fury, A4D-2 Skyhawk and F-100.



FIVE *Bullpups* **can be attached to wings of FJ "Fury" for assault on ground targets.**

U.S. NAVY MISSILES OF THE FUTURI

ASROC

A sophisticated anti-submarine rocket, *ASROC* is designed for launching from surface ships to seek subs at longer ranges than were possible with cancelled *RAT* (up to 10 miles through air plus limited underwater range). An acoustic homing device provides underwater guidance. Minneapolis-Honeywell has been awarded a research and development contract from Navy BuOrd.

ASTOR

A sub-launched weapon for use against enemy subs, *ASTOR* (Anti-Submarine Torpedo Ordnance Rocket) will carry a nuclear warhead. In development by Westinghouse Ordnance, it is electrically-propelled and wire-guided as it takes off from the launching submarine.

CORVUS

Designated *XASM-N-8, Corvus* is an air-to-surface missile specially designed for carrier-based aircraft, but also adaptable to shore based Navy and Marine planes. Its guidance system will home on enemy radar. Temco has development contract; Reaction Motors Div. of the Thiokol Corp. will supply the solid rocket; Texas Instruments and W. L. Maxson are working on electronic components.

EAGLE

A new trend in air-to-air missiles, *Eagle* is designed for use with relatively slow launching aircraft, with high performance built into the missile instead of the launching plane. This "standoff" weapon will have long air-to-air range—about 100 miles—and can be nuclear-fitted. The contractor is Bendix Aviation; so far, it has reached only the early stage of its long-range development.

GIMLET

A highly accurate unguided air-launched rocket. Its existence has been confirmed by Department of Defense, its contractor has not been identified. Status: now in development.

SUBROC

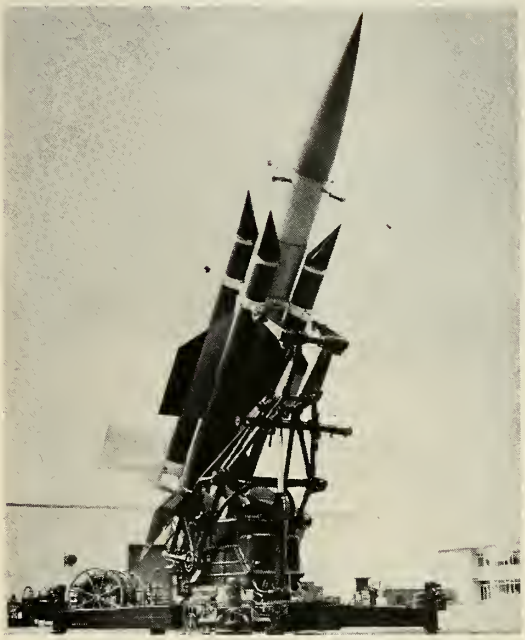
Goodyear Aircraft has a $65,000,000 contract for research and development work on *Subroc*, an anti-sub missile which can be launched from above or below the surface. *Subroc* system can detect enemy sub at long range (25-50 miles), compute its course and fire the missile. *Subroc* is expected to be defensive weapon for *Polaris* subs. Working with Goodyear are Librascope, Inc. and Kearfott Co., all under the technical direction of the Naval Ordnance Laboratory, at White Oak, Md.

TARTAR

A surface-to-air missile designed for use aboard destroyers, *Tartar* is a junior version of *Terrier* but it has about the same range. It employs beam rider guidance and is powered by a single solid rocket of about 15,000 pounds thrust. In advanced development, it is scheduled for early fleet use aboard three guided missile cruisers and 18 destroyers. Range is about 10 miles, speed above Mach 2 and warhead conventional. Prime contractor for the *Tartar* system is Convair/Pomona, a division of General Dynamics Corp.

GREAT BRITAIN

BLUE STREAK

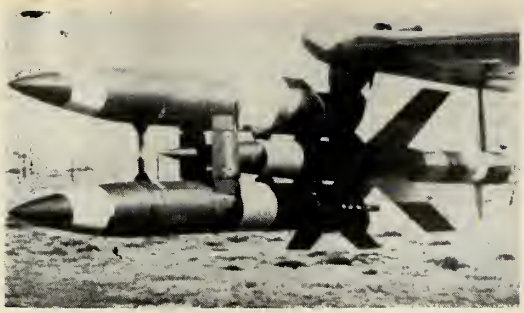


Britain's only long-range missile project, *Blue Streak* is an intermediate range ballistic missile designed to carry a thermonuclear warhead over distances up to 2000 miles. Ten feet in diameter, *Blue Streak* is more than 60 feet long, roughly the size of the American *Thor*. It is intended to be a "hard-based" missile, launched from underground bombproof silos. Prime contractor and coordinating authority is de Havilland Propellers Ltd., with Rolls Royce, de Havilland Aircraft and Sperry Gyroscope Ltd. as associated contractors.

THUNDERBIRD

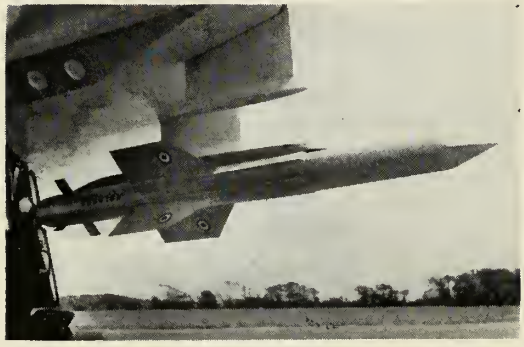
A surface-to-air missile for use by both the Royal Army and the Royal Air Force, *Thunderbird* is similar in performance and operational use to the American *Nike-Hercules*. Designed for mobility and ease of handling, it is fired from a compact wheeled launcher. The solid-fuel *Thunderbird* is 21 feet long and has a wing span of 5 feet, 3 inches; the center section has a diameter of 21 inches. English Electric is prime contractor. Missile is in production.

BLOODHOUND



Another British surface-to-air weapon, *Bloodhound* is boosted by a solid-propellant rocket to a velocity of 1500 feet per second and sustained on the rest of its flight by two Bristol 16-inch Thor ramjets delivering 15,000 pounds of thrust. *Bloodhound* is 15 feet long and 16 inches in diameter. Guidance is by semi-active homing. Cooperating contractors are Bristol Aeroplane, which manufactures frame and engines, and Ferranti Ltd., which supplies the guidance system. *Bloodhound* is in production for the Royal Air Force.

SOLID-FUELED *Thunderbird* **elevated on mobile launcher.**



RAF's *Bloodhound* **on guard, North Coates, Lincolnshire.**

DEVELOPED early, *Fireflash* is now a standard weapon.

FIREFLASH

Britain's first operational air-to-air missile, the Fairey *Fireflash* went into development shortly after World War II and was first tested in 1953. *Fireflash* has no sustainer rocket; it is launched by two solid-propellant boosters wrapped around the missile. Body is tubular with cruciform wings. Guidance is by Marconi beam rider. *Fireflash* is carried as armament on the Supermarine Swift MK. 7, the Hawker Hunter and the Australian-built Avon-Sabre. It is now used as a training weapon for the Fighter Command.

INFRARED-guided *Firestreak* attached to a Sea Vixen.

FIRESTREAK

In development for the past six years, *Firestreak* is a more advanced air-to-air missile than *Fireflash*. *Firestreak* is a slim, tubular weapon 7 feet long with cruciform wings and fins. Power is supplied by a single solid-propellant rocket. Range is about eight miles. An infrared detection system which homes on enemy engine exhaust provides guidance. *Firestreak* is carried on under-wing mounts on the Gloster Javelin, English Electric P1 and de Havilland Sea Vixen. Prime contractor is de Havilland Propeller. The missile is in service with the Royal Air Force and in production for both the RAF and the Royal Navy.

FIRING a *Seaslug* from triple launcher of destroyer.

SEASLUG

A fleet defense weapon for the Royal Navy, *Seaslug* is a surface-to-air weapon carried aboard guided missile destroyers of the Hampshire Class. It is fired from triple deck launchers which automatically compensate for ship roll. Guidance is by semi-active homing, integrated with the destroyer's radar. *Seaslug* is powered by a solid-fuel sustainer rocket and boosted initially by four dry rockets mounted concentrically around the missile. The boosters are jettisoned after burnout. Prime contractor is Armstrong Whitworth; General Electric Co. Ltd. has guidance responsibility and Sperry the control system.

HEAVIEST tanks are vulnerable to solid-fueled *Vigilant*.

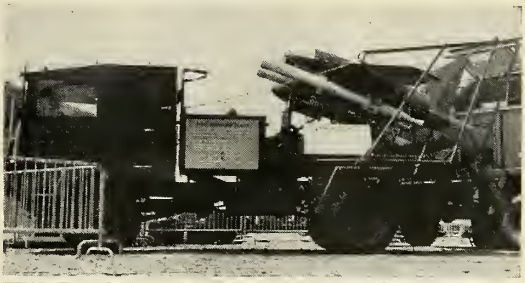
VIGILANT

An Army short-range battlefield missile, *Vigilant* has a pistol-like firing mechanism which guides it toward its target. Primarily an anti-tank weapon, it is carried in a portable launching cannister which weighs only 45 pounds and can be handled by one man. Solid-fueled, the missile is 53 inches long and has a wing span of less than one foot. Prime contractor is Vickers Armstrong Ltd.

FRANCE

SS-10, SS-11

A versatile missile which can be launched from jeeps, tanks, aircraft or helicopters, *SS-10* and *-11* are short-range battlefield weapons designed primarily for anti-tank use. They are wire-guided and solid-propelled. The missiles have been ordered by nine countries, including U.S. *SS-11* is longer-ranging version. Contractor is Nord Aviation.



FRENCH Alouette helicopter with four deadly *SS-11's*.

ENTAC

Built by DEFA, *Entac* is similar in use and nearly identical in range and velocity. Also wire-guided and solid-fueled. In production.

SE 4200

A product of Sud Aviation, *SE 4200* is a short-range winged missile. It is launched from a truck-mounted ramp by solid boosters which drop off. Range is about 60 miles. High-explosive charge is carried beneath the missile in a pod.

TWO French Army battalions are armed with the *SE-4200*.

PARCA

In production, the DEFA (Army Arsenal) *Parca* is a surface-to-air weapon with a maximum speed of close to Mach 2 and a range of 14 miles. It is a beam rider and its warhead is detonated by proximity fuze. Power is supplied by a liquid rocket plus four solid boosters. Missile weighs slightly more than one ton.

TAKE-OFF of surface-to-air *Parca*, now in production.

SE 4300

A surface-to-air weapon similar in principle to *Nike*, Sud Aviation's *SE 4300* is used as a training vehicle by the French Army. Subsonic, it has a range of 12 miles. Liquid-fueled, it weighs one ton.

MARUCA

Subsonic, *Maruca* is a short-range anti-aircraft missile for use on ships of the French Navy. Fifteen feet long, it has a 5 foot, 3 inch span. Liquid-propelled, it has a range of about 10 miles. It is built by Ruelle Naval Arsenal.

LIQUID-fueled *Maruca* guards fleet against air attack.

WITH same job as *Maruca, Masurca* is bigger and faster.

SEMI-TRAILER carries the solid-boosted MATRA *R. 422.*

MASURCA

Another product of the Ruelle Naval Arsenal, *Masurca* is a larger anti-aircraft weapon. Supersonic, it has a 15-mile range. It is 18 feet 8 inches long and has a span of 3 feet 3 inches. Solid-propelled, it weighs slightly more than one ton with boosters.

MASALCA

The Latocoere *Masalca* is a small interceptor missile for use on small ships of the French Navy. It is designed to stop enemy aircraft at ranges up to 60 miles.

TRIDENT

A pilotless aircraft type of surface-to-air weapon, *Trident* is similar in principle to the American *Bomarc*. Liquid-propelled, it is built by Sud Aviation.

TYPE 422

Capable of speeds over Mach 2, the MATRA *R. 422* is a two-stage surface-to-air missile fired from a mobile launcher-transporter. It has a solid booster and a solid sustainer in the second stage. Built and tested in limited numbers, it employs a command guidance system. An advanced "B" version has a range of 30 miles.

TYPE 510, 511

These are MATRA-built air-to-air weapons to be used by various fighters of the French L'Armee de l'Air. *M. 510* is 10 feet long, weighs 350 pounds and has a speed capability of close to Mach 2. It is in production. *M. 511*, externally similar, features an improved guidance system.

TYPE 5103

Built by Nord, the *5103* is an air-to-air missile using beam-rider guidance. Powered by a solid-fuel booster and a solid sustainer, it is in production.

AA.20

A MATRA-built air-to-air weapon, the *AA.20* is used on Mystere A and B fighters. In production, the liquid-propelled missile has a speed of Mach 1.5 and a range of one mile.

R.051

Also built by MATRA, the *R.051* is a solid-fueled air-to-air weapon, about 10 feet long and weighing 350 pounds. It is used on Mirage and Voutour fighters. Speed is Mach 1.5. In production.

BB-10

A guided-bomb type of weapon, *BB-10* features cruciform fins, an annular shroud wing and canard surfaces. It is radio-controlled.

ITALY

AIRONE

Built by Polverfizi Giovanni Stacchini, *Airone* is a short-range surface-to-surface weapon. Solid propelled and unguided, it has a range of about 6 miles.

C-7

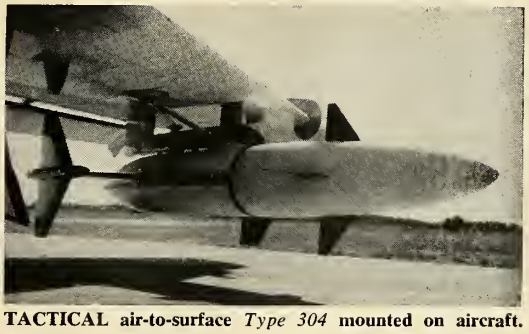
Centro Studi Propulsione a Reazione builds the *C-7*, an air-to-air missile. A solid-fuel engine provides power and the missile is guided to its target by an infrared homing system.

ORIONE SAR

A Stacchini product, *Orione Sar* is a limited-range surface-to-air weapon. Winged, with a 15-foot span, it is about 6 feet long.

ROBOTTI

Robotti is the name for a family of battlefield rockets under development by Motofides. The basic rocket is unguided, supersonic, about 16 feet long and 4 feet in diameter.



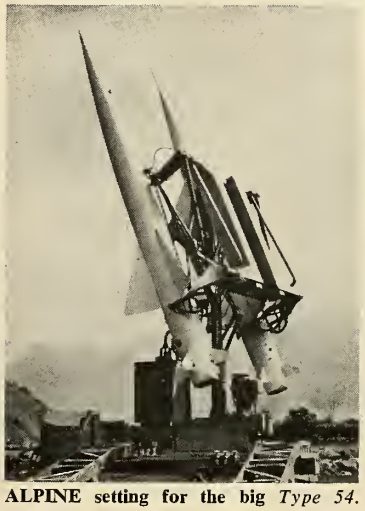
SWEDEN

TYPE 304

About 12 feet long with winged tail and small forward control fins, the Bofors *Type 304* is a tactical air-to-surface missile. The SAAB-32 Lansen all-weather attack plane carries two of these missiles on underwing mounts.

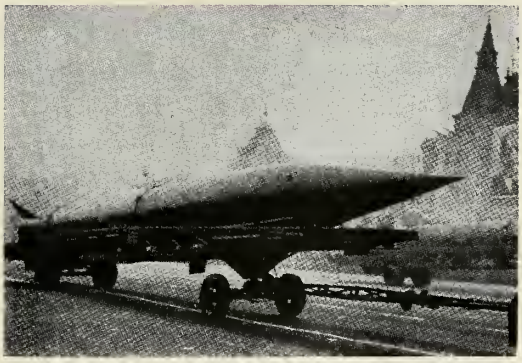
TYPE 315

This is a surface-to-surface weapon, deck-launched from destroyers. About 14 feet long with booster, it has a cruciform tail and small control fins in the nose section.



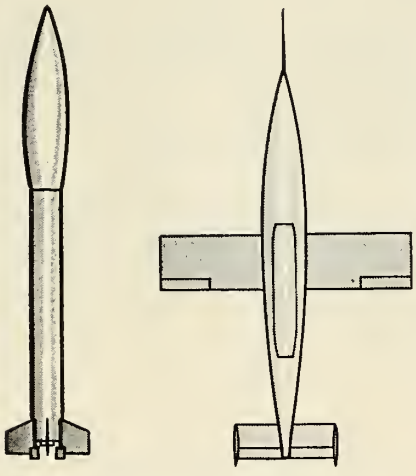
TACTICAL air-to-surface *Type 304* mounted on aircraft.

SWITZERLAND



TYPE 54

A surface-to-air anti-aircraft weapon, *Type 54* is built by Oerlikon. Twenty feet long, it has a 16-inch diameter and weighs about 800 pounds. A 2000-pound-thrust liquid rocket provides power. Guidance is by beam-riding; warhead has proximity fuze. Advanced versions known as *Types 56* and *57* are in development; *Type 54* is in production.



ALPINE setting for the big *Type 54*.

SOVIET UNION

NUCLEAR warhead-packing *T-1*, copied from German *V-2*.

M-100A J-2

UNGUIDED *T-5B* artillery rocket shown in Moscow parade.

M-100A

Although little is known of Soviet air-to-air missiles, this type made its first appearance in Korea as an unguided rocket. Later version is believed to have infrared guidance. About 8 feet long, it has a range of about 5 miles. It is solid-propelled. Speed is Mach 2-plus.

J-2

Basically a target drone, *J-2* is a pilotless aircraft type of vehicle also adaptable as a surface-to-surface missile or as an anti-submarine weapon. Subsonic, its range is in the 500-mile category. It is launched by a pair of solid boosters and sustained by an axial-flow turbojet. It is radio-guided.

J-3

An advanced version of *J-2*, the *J-3* is also a pilotless aircraft type, but with swept wings rather than the straight wings on its predecessor. It has four boosters for launch, and in addition to the turbojet sustainer it has a 15,000-pound-thrust ramjet engine which gives it supersonic capability. Its range is 450 miles and it is radio/radar-guided. *J-3* is 38 feet long and has a span of 23½ feet. It carries a one-ton warhead.

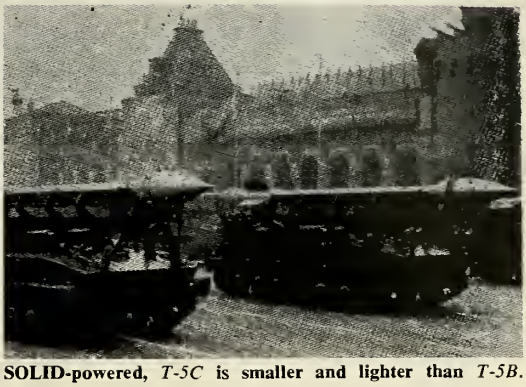
M-2

M-2 is a two-stage surface-to-air weapon developed from the German *Rheintochter*. In service, it is launched from mobile units. The 25-foot missile has a speed in excess of 1500 miles per hour. Guided by radar and infrared, it employes solid propellants in both stages.

COMET

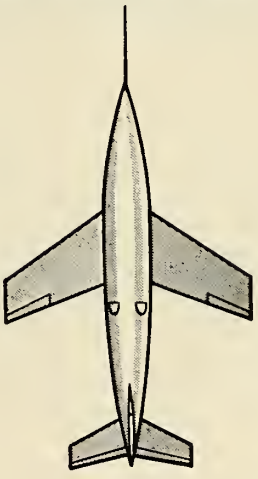
This is a family of surface-to-surface missiles which originally started as a research vehicle. *Comet 1* is a short range (100 miles) single-stage weapon in operational service, reportedly also used as a sub-launched missile. It is powered by a single solid-fuel engine. *Comet 2* has a greatly improved powerplant and an inertial guidance system. Its range is in the 500-600 mile class. The 44-foot missile is in production.

ME (IGOR)



One of the earliest Soviet missiles, the *ME* is an anti-tank rocket of the bazooka type. It is two feet long and has a diameter of 3 1/3 inches. It is powered by a sulphur-based solid rocket with a three-second burning time. The weapon supposedly has a maximum range of two miles but its effective range against tanks is about 1000 yards.

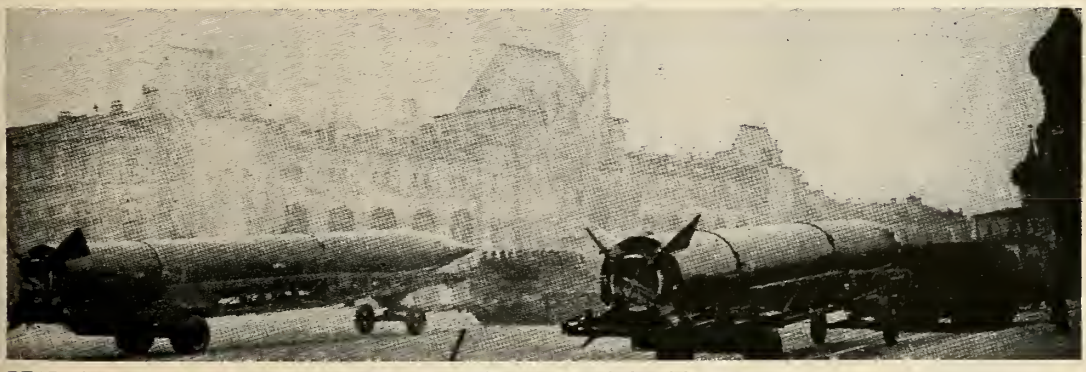
T-1



A Soviet copy of the German *V-2*, *T-1* is a surface-to-surface missile in the medium-range bracket. Frequently seen in Red Square parades, *T-1* has been operational for some time. It is equipped with a mobile, self-propelled launcher. About 50 feet long, *T-1* employs a liquid-fuel rocket engine. It is guided by a radio-inertial system. Grossing about 20 tons, it is equipped with a nuclear warhead.

T-2

The mainstay of the Soviet missile arsenal, the *T-2* has been deployed to a number of bases in Soviet Europe and reportedly has also been concentrated along the southern flank of the satellite countries to cover American air bases in North Africa. Although it stemmed from the German *V-2*, *T-1* is a greatly advanced version, with a range of more than 1500 nautical miles. A two-stage weapon, it grosses about 60 tons and overall length is more than 100 feet. It has a liquid-propellant (oxygen/alcohol) powerplant in each stage, and guidance is supplied by a radio-inertial system. Warhead is nuclear.

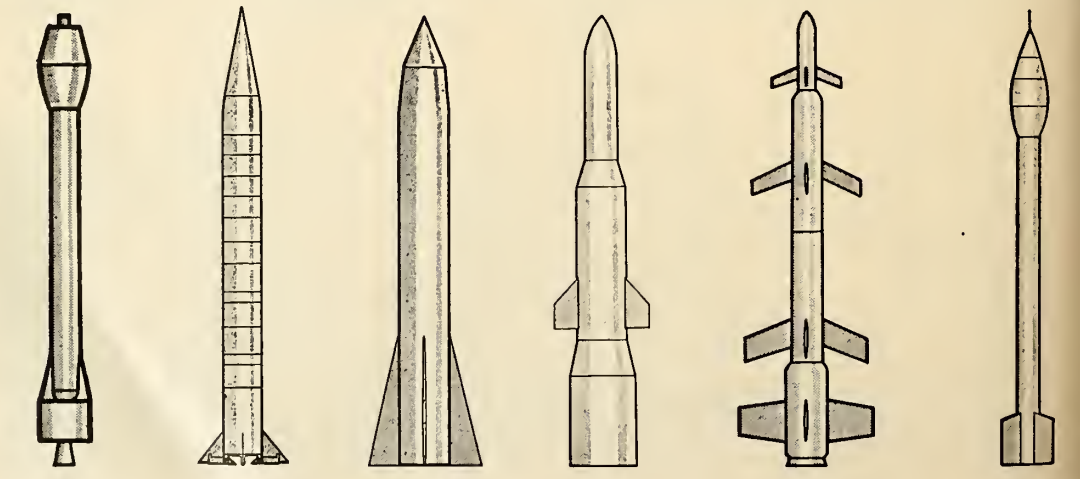


SOLID-powered, *T-5C* is smaller and lighter than *T-5B*.

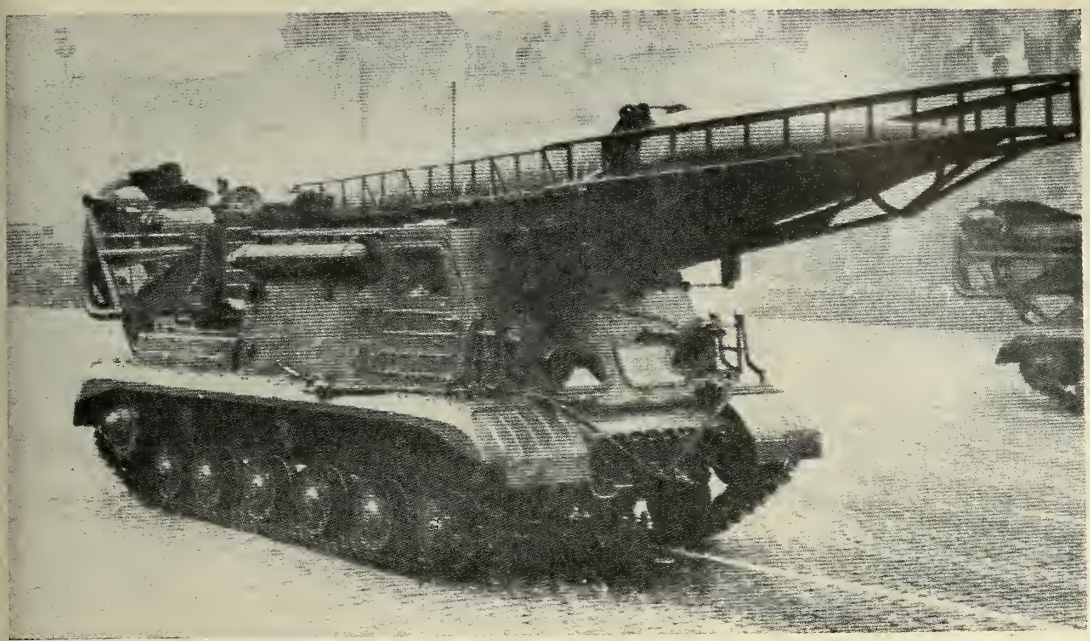
J-3

M-2

REAR view of the highly mobile, operational *T-1*, guided by a radio-inertial system.



TWO-STAGE surface-to-air *M-2* travels at better than 1500 mph and is guided by both radar and infrared.



T-3

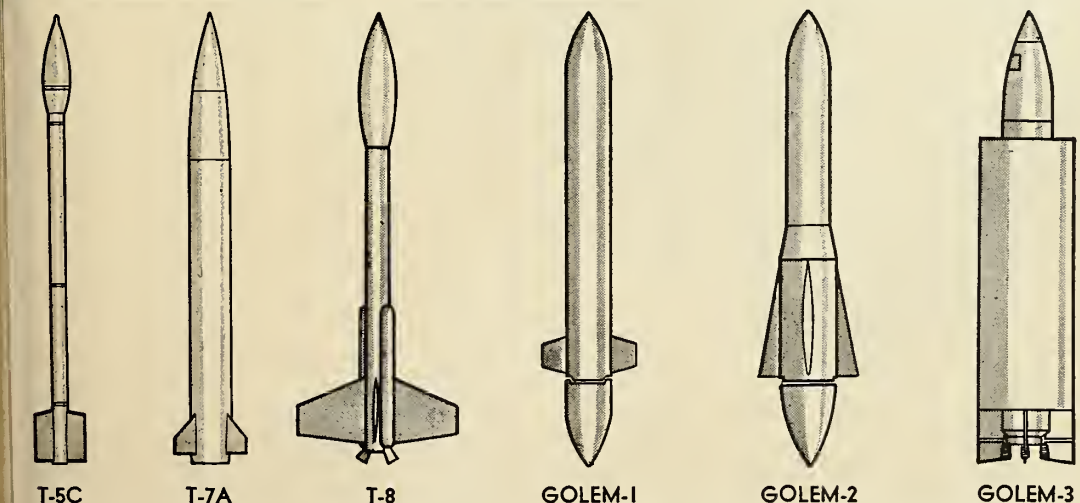
The much-discussed Soviet intercontinental ballistic missile, *T-3*, according to qualified authorities, is scheduled for operational service in 1959. Like the American *Atlas* and *Titan*, it is designed to carry a thermonuclear warhead more than 5000 miles. It is a two-stage missile employing high-thrust liquid-fuel engines in both stages; estimates of the amount of thrust vary widely. The missile has an overall length of 100-125 feet and it grosses about 85 tons. Guidance is radio-inertial. An advanced version of this weapon is known as *T-3A*. This version, in development production status, has an estimated range of more than 6000 miles and a velocity of 16,000 miles per hour. Like *T-3*, it is a two-stage liquid-fuel missile with a higher thrust engine in the first stage.

T-4

Capable of delivering a one-ton warhead over a distance of 1000 miles, *T-4* falls in the medium-range ballistic missile category. It is 50-55 feet long and has a diameter of 6½ feet. Grossing 35 tons, it is a two-stage weapon, both stages liquid-fueled. Warhead is nuclear.

OPERATIONAL *T-7A* **is comparable to U.S. Army's** *Corporal* **and has a range of 70 miles and solid-fuel powerplant.**

T-4A



This is the Soviet counterpart of the American *Dyna-Soar* boost glide bomber, stemming from German *Saenger-Bredt* antipodal bomber in design status at the end of World War II. Although reliable sources have reported that the U.S.S.R. is working actively on this project, its status is unknown.

T-5

A short-range artillery rocket, *T-5* is one of the earlier Soviet missiles. Grossing about 2½ tons, it is 32 feet long and 3 feet in diameter. A *T-5* field battery has six launchers each. The rocket is unguided.

T-5B, T-5C

Also artillery rockets, *T-5B* and *T-5C* are later versions of the basic *T-5*. Both have been seen frequently in Moscow parades and both are in operational service. They are carried on self-propelled tank-like launchers. *T-5B* is 30 feet long and has a range of 25 miles. *T-5C* is a smaller weapon, 25 feet long and about a foot and a half in diameter. It has a solid-propellant powerplant. Both weapons are unguided.

T-6

Another surface-to-air weapon, *T-6* is a two-stage missile with a service ceiling of about 60,000 feet. The weapon grosses two tons and has a speed in excess of 1500 miles per hour. Its first stage has four solid boosters and there are two more solid rockets in the sustainer power plant for the second stage. It is radar-guided and carries a high explosive warhead with proximity fuze.

T-7A

The *T-7A* is an adaptation of a research rocket to military use as a short-range surface-to-surface missile. In service, it is about 25 feet long and about 2½ feet in diameter. Where the original version was liquid-propelled, the operational weapon has a solid-fuel powerplant. Comparable to the American *Corporal*, it has a range of 70 miles.

T-8

An anti-aircraft weapon, *T-8* is the Soviet counterpart of the American *Nike-Ajax*. In service for several years, it has a range of 15 miles and carries a high explosive-proximity fuzed warhead. Speed is Mach 2-plus. The missile is boosted by two solid-propellant rockets; a larger liquid rocket of 4600 pounds thrust powers the second stage. Fired from mobile launchers, it is used by field batteries in non-permanent positions.

GOLEM-1

Another missile adapted from German World War II work, *Golem* is an underwater-to-surface weapon launched from a chamber which is towed by a submarine. In production, it has a range of about 400 miles. It has a liquid-fuel engine which burns oxygen and alcohol and it employs a radio inertial guidance system. Grossing 16½ tons, it is 54 feet long.

GOLEM-2

A longer-ranging underwater-to-surface missile, *Golem-2* is reportedly a naval version of the *T-2* IRBM. A two-stage weapon like *T-2*, it has liquid-fuel engines. Launching is from the towed underwater chamber, as in *Golem-1*. *Golem-2* is 57 feet long, 7 feet in diameter and has a range of about 1200 miles. It is still in developmental status.

GOLEM-3

An anti-aircraft weapon designed for launch from a submarine or surface vessel, *Golem-3* has a range of about 8 miles and reportedly has underwater launch capability. It is 17 feet long and 2 feet in diameter. Power is supplied by a 15,000-pound-thrust solid-fuel engine. The missile weighs 2.2 tons and is guided to its target by an infrared system.

MODEL of *Sputnik III* satellite dramatizes peaceful use of launching capability. Inset shows "ion trap."

Have sidearms, will travel

When SAC slings a pair of GAM-77 Hound Dog air-ta-graund missiles under the wings af the new B-52G bamber, it has what amaunts to a brand-new manned weapan system.

Far the Hound Dog's jet engine drives it at supersanic speed ta a target hundreds af miles away. Its self-cantained inertial autonavigatar, set befare launch by the B-52's crew, can't be jammed, can't be decayed.

The GAM-77 Haund Dag pragram gat underway in August, 1957. The missile is already in its flight test phase. Thanks to accelerated develapment, it will be deplayed by 1960.

SAC's and ARDC's "blue-suit" integratian programs further speed the Hound Dog's aperatianal status. As every other test missile comes aff the praductian line, half the crew assigned ta it is fram the Air Farce.

The Missile Divisian af Narth American Aviatian is weapan system contractor for the GAM-77 Haund Dag.

MISSILE DIVISION

NORTH AMERICAN AVIATION, INC., DOWNEY, CALIFORNIA

Saturn's Test Tower To Be Ready by Sept. 1

HUNTSVILLE—Construction work was completed last week on the modification of the 145-foot rocket engine static test tower at Redstone Arsenal to accommodate the 1½-million-pound-thrust *Saturn* booster.

The Department of Defense says it expects the tower will be ready for use when support facilities are finished Sept. 1. The *Saturn* test vehicle will be delivered to the Army Ballistic Missile Agency's Test Laboratory in November. The first static testing is due in December.

ABMA is developing the *Saturn* booster, a clustering of eight H-1 liquid propellant motors—for the Advanced Research Projects Agency, Department of Defense, for heavy space applications. The booster will stand 75 feet tall and have a diameter of 22 feet.

Steel pilings were driven down to bedrock, in some cases as far as 60 feet, to provide structural support for the test tower. The $850,000 job has been in progress since January. In addition to a new structural steel test position the work consists of an enlarged blast deflector pit, a steel buttress for additional horizontal strength, and two 101-foot steel girders that help support a super-structure housing a crane hoist atop the concrete tower.

Earlier, ARPA announced selection of a modified **Aerojet** first *Titan* stage and a new **Pratt-Whitney** and **Convair** *Centaur* rocket as the second and third stages of the *Saturn* project, which is to provide a reliable system for lifting multi-ton loads into high orbit and deep space by 1962 or 1963.

The three-stage *Saturn* will weigh at liftoff about 580 tons of which about 500 tons will be propellants, and will stand about 200 feet tall.

The modified *Titan* second stage will be somewhat longer than its regular 54 feet and will be 10 feet in diameter. It will provide a 360,000-pound thrust. The third-stage *Centaur* will use two rocket engines with combined thrust of 30,000 pounds and be 10 feet in diameter.

The vehicle will have an all-inertial guidance system to automatically compensate for loss of thrust if one of the booster engines should fail.

The third-stage *Centaur* is being developed by Pratt & Whitney, and Convair.

people

TRUAX

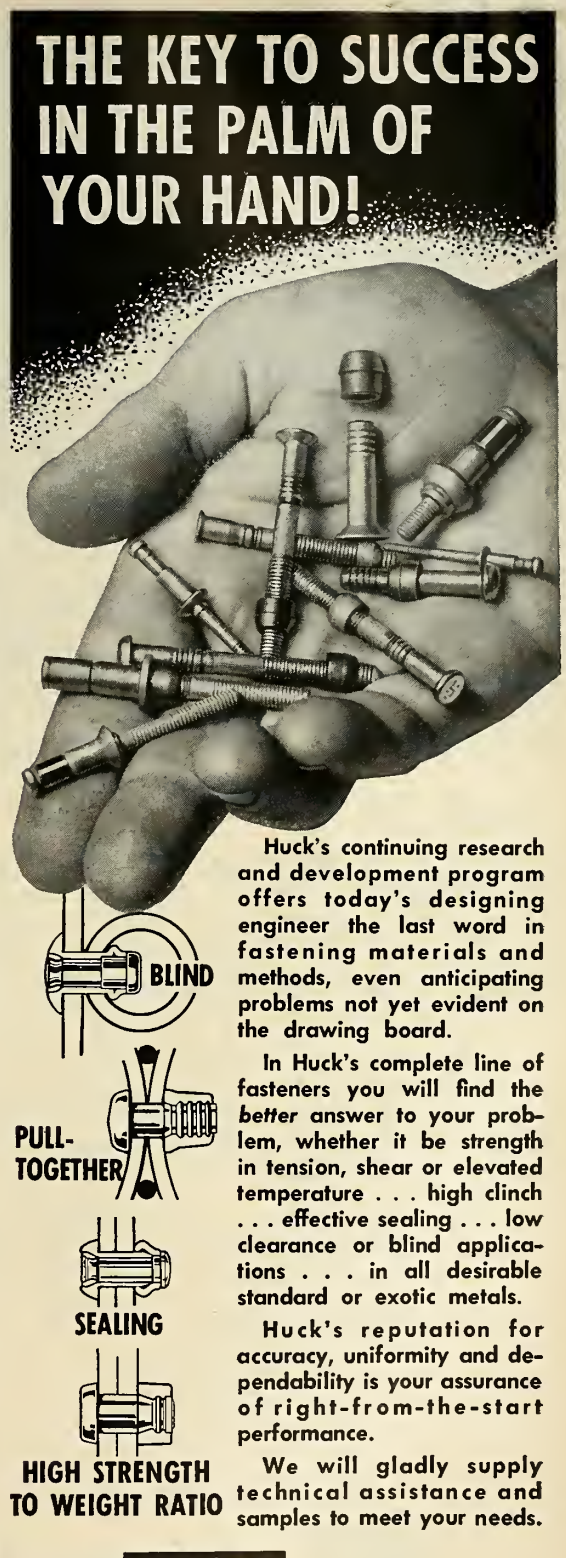
Capt. Robert C. Truax, USN, (Ret.), former national president of the American Rocket Society, has joined Aerojet-General Corp. as director of Advanced Development at its Liquid Rocket Plant in Sacramento. Truax, 42, who has spent almost his entire professional career in the development of rockets, guided missiles and satellites, received the Robert H. Goddard medal in 1951 for his outstanding work in rocket development and last year was awarded the Navy's Legion of Merit decoration for his contribution to the *Polaris* program. (See M/R profile, November, 1957, p. 114.)

WAWRA

Aerojet also has named **Cecil W. Wawra** of Paris director of European Operations. He will coordinate the company's activities in Western Europe, concentrating on projects in which A-G is associated with European companies in national or NATO defense programs. From 1951 to 1956, Wawra represented the General Tire and Rubber Co., parent-company of Aerojet, at Rome, and since 1956 has represented both General Tire and Aerojet-General in Paris.

MILLER

Dr. Curt E. Miller, a specialist in aero and space medicine, has joined the Aeronautics Division of Wiancko Engineering Co., where he will conduct research on animal instrumentation and the effects of inertial forces and other space environmental factors associated with getting man into space.



Matthew H. Portz became the National Aeronautics and Space Administration's Western Public Information Officer on July 13. Located at the NASA Western Coordination Office, 150 Pico Boulevard, Santa Monica, Calif., he will be responsible for information activities in Southern California and neighboring states. Portz is transferring to the new post from the NASA Lewis Research Center, Cleveland, where he has been Information Officer since August, 1956. His successor at Lewis is **Harry J. McDevitt Jr.,** formerly of the General Electric Co. News Bureau.

LUNGER

Election of **Wilbur E. Lunger** as staff vice president of manufacturing, and **H. Ben Young** as staff vice president of engineering and research of ACF Industries, Inc., has been announced. Both of the new corporate vice presidents were officers in ACF operating divisions—Lunger as vice president of manufacturing with American Car and Foundry division in New York City, and Young as director of engineering and research at W-K-M division, Houston.

Henry P. Steier, former M/R electronics editor, has been named corporate director of Public Relations for Lear, Inc. Immediately prior to joining Lear, Steier was special assistant for Technical Information to E. R. Quesada, Federal Aviation Agency administrator. He was with American Aviation Publications, Inc., publishers of M/R, from 1955 to 1958 after holding increasingly responsible positions in the electronics engineering field. Steier was a major contributor to the design and development of the first high-production cathode ray tubes for commercial television and holds patents in the field of electron optics and secondary emission techniques.

Huck's continuing research and development program offers today's designing engineer the last word in fastening materials and methods, even anticipating problems not yet evident on the drawing board.

In Huck's complete line of fasteners you will find the *better* answer to your problem, whether it be strength in tension, shear or elevated temperature . . . high clinch . . . effective sealing . . . low clearance or blind applications . . . in all desirable standard or exotic metals.

Huck's reputation for accuracy, uniformity and dependability is your assurance of right-from-the-start performance.

We will gladly supply technical assistance and samples to meet your needs.

A "TIME-TABLE" FOR SPACE CONQUEST

BY **1963** – INSTRUMENTED PLANETARY SOFT LANDING

BY **1968** – SPACE STATION FOR STAGING TO MOON AND PLANETS

BY **1970-75** – MOON BASE

These predictions were made by Alexander Kartveli, Vice-President for Research & Development at Republic Aviation, and one of the most optimistic of the 56 leading space experts of the world who were consulted by the U.S. House of Representatives Committee on Astronautics & Space Exploration for its report: "The Next 10 Years in Space, 1959-1969."

JOIN REPUBLIC IN AN **INTEGRATED ATTACK** ON PROBLEM AREAS OF **SPACE EXPLORATION**

It's the fervent conviction of engineers and scientists at Republic Aviation that the courageous "Space Time-Table" above is entirely feasible – given a tradition-free, integrated approach to the problems. Such an approach is evident at Republic Aviation. Here, groups of specialists from many disciplines are working in close collaboration to solve problems across the entire spectrum of space technologies, which limit today's interplanetary and upper atmosphere flight capabilities.

Expanded by $35,000,000 last year, Republic's integrated Research and Development program has already produced signal advances in space guidance concepts; in new propulsion systems (plasma, nuclear); in radiation physics; in new materials and processing techniques; in unique hypersonic configurations; and in prototype development of hardware (as an example: hydraulic systems that operate reliably up to 1000°F).

Professional men—who can meet new challenges with enthusiasm and dedication – are urged to look into openings with our R&D groups, working in an atmosphere of exhilarating intellectual adventure.

reviews

ZIRCONIA: ITS CRYSTALLOGRAPHIC POLYMORPHY AND HIGH TEMPERATURE POTENTIALS, B. C. Weber and M. A. Schwartz, Aeronautical Research Laboratory, WADC, 26 pp, available from OTS, U.S. Department of Commerce, Washington 25, D.C.

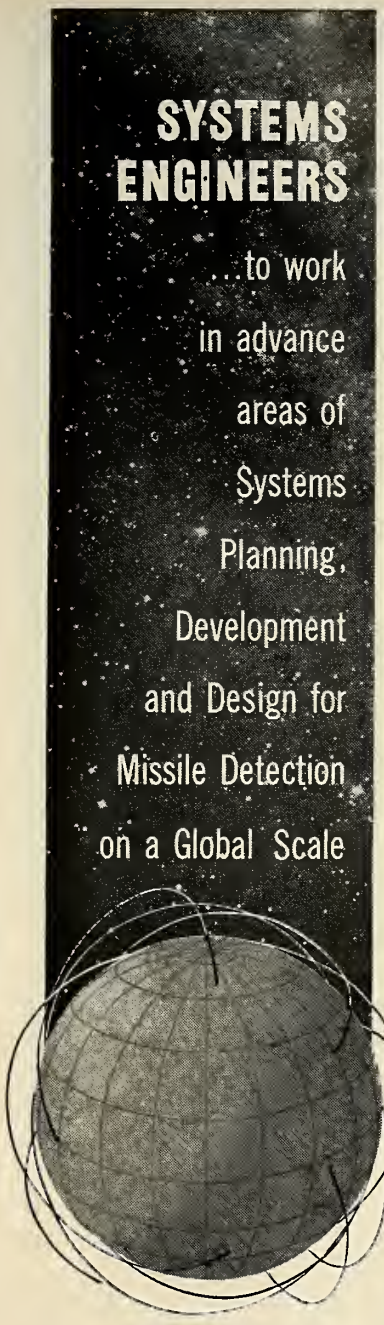
Zirconia (ZrO_2), with its melting point of 4850°F, is one of the most promising materials for high-temperature applications, according to this report. In addition to being among the most stable of the refractory oxides, it has very high strength, good corrosion resistance, hardness, high thermal shock resistance, and high thermal conductivity—qualities important in rocket, ramjet, and missile applications. The report clarifies some of the controversial data presented in literature concerning this refractory metal, reviews the chemistry of zirconia, and presents some of its future potentialities.

Also described are advancements in metal-modified oxides. According to the report, the usefulness of zirconia is now dependent on controlling its crystallographic transformation.

CTR-292 FIBER GLASS AND GLASS LAMINATES, 1930-58, available from OTS, U.S. Department of Commerce, Washington 25, D.C.

A catalog of technical reports which lists all reports of research in the fields of fiber glass and glass laminates has been published by the Office of Technical Services, U.S. Department of Commerce.

Many of the reports listed are the result of research conducted for the Army, Navy, Air Force, and other agencies of the U.S. Government. Others are German documents captured by the Allies during World War II.



SOVIET RESEARCH IN LUBRICANTS AND LUBRICATION: Dec. 1958, 27 pp, available from OTS, U.S. Department of Commerce, Washington 25, D.C.

Russia and her satellites were not ahead of the United States in the field of lubricants and lubrication at the beginning of 1958, but were trying to gain headway by studying the work of others, Soviet literature indicates.

According to a survey of published Russian literature by a U.S. Government agency, "It appears that Soviet scientists are not ahead in any process, products, or applications." The study included material on lubrication, lubricants and additives, and formulation of lubricating compositions.

The review of abstracts of Russian technical reports appearing from 1950 to the end of 1957 showed that Red researchers were apparently concentrating on areas fairly well known and defined by U.S. scientists.

This may mean, the survey concludes, that while the Soviets realized the po-

These positions are with the Missile Detection Systems Section of General Electric and require high technical and creative capacities. All assignments offer fruitful opportunities to make state-of-the-art advances with an organization that encourages and rewards the individual contributor. The ability to function both through individual action and team leadership is highly valued. Current openings are in these areas:

ADVANCED RADAR SYSTEMS PLANNING

Work in this area calls for engineers able to visualize and define future defense and space problems and conceive advanced radar systems to solve them.

RADAR SYSTEMS ANALYSIS & DEVELOPMENT

An advanced degree and/or strong background in systems analysis and design is essential for such assignments as:

...analyze and define requirements for advance detection systems and determine broader parameters for such systems; establish their feasibility.

...analyze long range missile detection systems and specify optimum configuration on the basis of utility, performance, cost and delivery.

SPECIALISTS IN ELECTROMAGNETIC PROPAGATION

PhD or MS is required in this area. Scientists will carry out analysis of propagation phenomena, as related to long range missile detection. Plan detailed investigations and illustrate practicability of results. Ability to assume responsibility essential.

OPPORTUNITIES IN D & D OF RECONNAISSANCE RECEIVER DESIGN & SYSTEMS EQUIPMENT

Assignments require specialized background in one or more of these areas: VHF and UHF frequency spectra (P & L bands) • ECM • Microwave; wave guide components, Duplexers, switches, hybrids; VHF and UHF transmitters.

ALSO POSITIONS IN COMPUTER APPLICATIONS

(Knowledge of large business or special purpose computers needed) and COMPUTER PROGRAMMING (experience with IBM 704 & 709 needed.)

creates key positions with

"growing room" for

electronic engineers

Billion-dollar United Aircraft Corporation has long been a pace-setter in aerodynamics, themodynamics, propulsion, air frames, airborne equipment, etc. Now, establishment of a new division has placed the Corporation squarely in the *integrated electronic systems* field.

THE MEN WE SEEK have had experience in electronic sub-systems and are now prepared for Weapons Systems Management wherein they must view the entire concept of integrated systems. We solicit skills in

- Communications Systems
- Computer Systems
- Inertial Guidance Systems
- Fusing and Arming
- Ground Support
- Guidance Systems
- Radar Systems
- Feedback Controls
- Autopilots

BENEFITS: Connecticut countryside living — ultra sophisticated projects dealing with advanced flight systems, missile systems, orbital and lunar studies — "first aboard," wide-open opportunities to start high, move higher — the finest corporate-owned research facilities anywhere — company supported advance degree programs — and the revealing fact that we acknowledge how vital is electronics to this weapon systems field.

If you are serious about your career, then you owe it to yourself to write immediately to Mr. John North at:

missiles & space systems

tential importance of the field, they were not especially proficient in it.

A large amount of research, the report observes, was being expended on hydrocarbon chemistry, an effort which could lead to new petroleum processes and products.

ON THE PROBLEM OF RE-ENTRY INTO THE EARTH'S ATMOSPHERE, A. C. Robinson and A. J. Besonis; WADC, U.S. Air Force. 68 pp. $1.75. Available from OTS, U.S. Department of Commerce, Washington 25, D.C.

Problems concerned with safely recovering a manned satellite after it has orbited the earth or gone around the moon are presented in this Air Force report from the standpoint of deceleration, heating, and accuracy of impact.

The study indicates further that simple, non-lifting re-entry will be feasible from satellite orbits. It appeared possible to achieve impact accuracy sufficient for ground installation, suitably alerted, to find the vehicle. The lunar re-entry, however, presents a severe total heat problem, and accuracy requirements are such that some lift or other control will probably be required.

Deceleration and peak heating rates were found to be no larger than those encountered in ballistic missile re-entries, but the total heat input was much larger because the heating lasts longer.

ORBITAL STORAGE OF CRYOGENIC FLUIDS, D. R. Cramer, WADC, U.S. Air Force. 13 pp. Available from OTS, U.S. Department of Commerce, Washington, D.C.

This Air Force report indicates that simple, multi-layer reflective-type shielding provides the answer to the problem of storing low-boiling point propellants during long space flights.

A study was made to determine if research on combined regenerative and radiative heat transfer techniques was necessary for the development of storage containers. It was found that for most containers of probable capacities, yearly liquid hydrogen losses can be maintained below an acceptable 5% if sufficient reflective layers are used.

Research specifically in the heat transfer area is not required for the development of such containers, the report concludes.

WELDING AND BRAZING OF MOLYBDENUM, N. E. Weare and R. E. Monroe, Defense Metals Information Center, Battelle Memorial Institute for Office of Director of Defense Research and Engineering, Department of Defense. 47 pp, $1.25. Available from OTS, U.S. Department of Commerce, Washington 25, D.C.

The report identifies the best methods, as drawn from the published literature, for welding molybdenum to itself.

It also provides guidelines for producing the most useful molybdenum joints. Metallurgical considerations involved in joining the metal are discussed, as well as cleaning and testing techniques.

Joining processes examined include fusion, resistance, and solid-state welding, and brazing.

From Little Acorns...

Recently, one of NASA's procurement chiefs showed me a photostat of the first U. S. Government airplane contract, dated Jan. 27, 1908. It called for construction by Wilbur and Orville Wright of a heavier-than-air machine sufficiently "demountable" to be carried on "an ordinary Army wagon." The contract price was $25,000. Scribbled in the margin of the document in faded ink was the prophetic phrase: "from little acorns . . ."

As space technology moves out of the acorn stage, the success of the United States program will continue to be in direct ratio to the quality of teamwork between government and industry. NASA's predecessor, the National Advisory Committee for Aeronautics, achieved a high degree of teamwork with the aircraft industry. When NASA was formed, it was determined that its space mission should not interfere with the type of service NACA used to provide.

Therefore, NASA was divided into two separate technical branches: the Office of Aeronautical and Space Research and the Office of Space Flight Development. Although the former will naturally be involved in research for NASA's own operational needs in space flight, it will also continue to provide research advice and assistance to the industry. However, most leaders of the aircraft/missile industry realize that NASA's principal mission for some time to come is research and development. They are also aware that an R&D organization seldom, if ever, deals in large production contracts.

Civilian-oriented science programs do not require busy assembly lines producing quantities of rockets and space vehicle components. With the possible exception of some workhorse vehicles, such as the relatively inexpensive *Scout*, the new large rockets designed for civilian purposes will be produced in limited quantity.

Thus, NASA will not be stockpiling vehicles and parts as the military programs must. The situation differs only slightly in the case of scientific payloads. Even in a series of experimental projects, such as the *Pioneer* space probes, the payload packages vary with each shot, according to the data to be collected. One type of vehicle will be used to launch several types of payloads. Both rockets and payloads, however, call for a very high degree of reliable design and assembly.

We have determined, for example, that further reliance upon *Juno II's* and *Thor-Ables* is uneconomical for space science purposes because they have limited load-carrying capacities and lack versatility. Neither vehicle has upper-stage guidance, so the payload must be spin-stabilized, thus restricting both its mass distribution and gross weight. Hence NASA's Fiscal Year 1960 *Juno II* and *Thor-Able* launching schedules have been curtailed and more funds and effort are being devoted to development of *Thor-Deltas* (which have coasting guidance) and to the larger *Vegas* and *Centaurs*. Future NASA vehicles — *Thor-Deltas*, *Vegas*, and *Centaurs*—can lift heavier payloads far more cheaply and efficiently than the *Juno II's* and *Thor-Ables*.

What, then, is the incentive for a company to develop a rocket or a scientific payload for NASA, only to have it become obsolete very quickly, with no production contracts to look forward to?

The answer lies in what rocket-industry leaders themselves have said repeatedly. They consider their work for NASA vital to the future of their companies because this agency is in the forefront of space research. These industry officials know that the positions and continued growth of their companies depend on the vigor of their research divisions. They also point out that despite the relatively small size of the NASA budget request for Fiscal Year 1960 ($485,300,000), NASA's priority is second only to that of national defense. Moreover, as NASA develops, its budget, too, will inevitably grow in the years ahead.

In final analysis, however, the greatest stimulus of all is the challenge to industry's technological capabilities.

Alex V. Topchiyev, a prominent member of the Soviet Academy of Sciences, once told a news conference that *Lunik* was ". . . a natural result of the free development of science and technology under socialism where boundless scope is given to human talent and genius."

If this situation can prevail in the USSR, then imagine what can be accomplished in a free society.

NASA is confident that our industry-government team will prove to the world's uncommitted peoples what we have always known; namely, that in the space realm, as in other fields of endeavor, democracy provides far and away the best climate for talent and genius.

DR. T. KEITH GLENNAN
Administrator, NASA

T. (for Thomas) Keith Glennan has been Administrator of NASA since it was created in 1958. An electrical engineering graduate of Yale, he served through World War II as director of the Navy's Underwater Sound Lab at New London. He then was associated with Ansco until becoming president of Case Institute in 1947. During 1950-52, Glennan served as a member of the AEC. He holds several honorary Doctor's degrees and is a Fellow of the American Academy of Arts and Sciences.

NEW PRODUCT BRIEFS

E EQUIPMENT. It may soon be possible to locate and permanently record roduction speeds lack of bond in ad honey-comb sandwich—both flat c curved shapes. The new Thermoaic method is now receiving final aation in the engineering-research cies of Magnaflux Corporation, higo, where several aircraft plants co-operating in tests. The method oices an exact pattern of every point od bond between the core material cskin, and of over-heavy braze as el The dark brown pattern remains anent, fixed on the skin's surface t removed by a solvent, thus perig photography for records, and ital examination of the section or n both vendor and customer plants sired. Installations will include full atic control, conveyorized spray es and controlled heat application.

No. 229 on Subscriber Service Card.

ES SHELLS. Thor Ceramics, Inc. anes a new range of epoxide resin el for encapsulating all types of comnts. Available holes and leads facilitassembling operations on winding rn The low water absorption characrics of thermosetting epoxide resin ot t the enclosed components from at and atmosphere. Sealing is acmished with liquid epoxy resin at ing the material of shell. The shells avi high tensile strength and operate a maximum temperature of 150°. eir excellent electrical qualities ova dielectric constant of 3.70 at 60 rcl with a low loss factor of 0.009. ari ions in shapes from tubular to ct gular may be ordered. Diameters ng from 1/8" to one inch and heights on 1/4" up. Identifying colors may also dered.

No. 230 on Subscriber Service Card.

EF ELING VALVE. A refueling valve #4-1755-000) is now available from ere Supply Mfg. Co. which is readily ada ble to unusual flow rates and to inc exotic and high energy fuels and he fluids. Normally the valve is built h dle a flow rate of 200 g.p.m. with erating pressure of 50 psi. Operin temperatures range from —65° – 60°F., fuel and ambiet.

No. 231 on Subscriber Service Card.

FUNCTIONAL MICROSOURCE. SIE (Southwestern Industrial Electronics Co.), a division of Dresser Industries, Inc., announces the introduction of its latest series of K-1 Microsource. The new K-1 Microsource is designed for use with any standard oscillator within its frequency range to produce small, known, controlled test signals. In addition, an internal battery and associated polarity-reversing switch are now incorporated to allow testing high-gain dc amplifiers. An added feature is the spring-loaded, momentary-on position in the dc "on-off" switch to allow generation of positive or negative test pulses. The new K-1 consists basically of a potentiometer, a rectifier type voltmeter and a shielded step attenuator. Voltages are set on the meter by the potentiometer, and multiples of the voltage selected by the step attenuator. Output is read directly on the front panel meter, and is continuously variable from zero to 10 volts, with a db scale also provided. The K-1 continues to feature the human-engineered appearance and functional ease of use pioneered by SIE in its Advanced Design Instrument line.

Circle No. 232 on Subscriber Service Cord.

CONTACTOR. A new secondary contactor which can be used with any dc welding power source to interrupt high amperage welding current has been announced by Air Reduction Sales Company. The unit is specifically designed as auxiliary equipment for Aircomatic (Airco's gas-shielded metal-arc process) and Heliweld (Airco's tungsten-inert-gas process) applications where the power source employed does not have a primary contactor. Rated at 600 amperes, the unit operates on 115 volts, single phase, 50 or 60 cycle current, and will effectively interrupt welding currents up to capacity at 100% duty cycle.

Circle No. 233 on Subscriber Service Card.

PLIER. Mathias Klein & Sons, has introduced a new oblique cutting plier designed with high leverage to do many of the jobs too tough for a conventional oblique cutter to handle. "Handform" handles assure greater ease and comfort in cutting. Catalog No. 228-8. Length—8 inches.

MISSILE LITERATURE

CHECKOUT TECHNIQUES. Ling Aviation Inc. has published a booklet reviewing automatic systems checkout as related to techniques instaad of equipment to permit broadest coverage of approaches applicabla to design of automatic systems checkout equipment.
Circle No. 209 on Subscribor Service Cord.

SEMICONDUCTORS. Ohio Semiconductors, a new company producing compound semiconductor devices and materials, offers full descriptive literature on the MS-41 Magnetoresistor, HS-51 Halltron, Hr-31 Halltron, MC-1 Magnetic Circuit and TA-11 "Thermo-Cell" Thermoelectric Junction. Each piece gives basic specifications, examples of applications and charts showing performance characteristics.
Circle No. 210 on Subscribor Service Card.

CATALOG. Electronic Speciality Co. announces the publication of a new 40-page catalog, No. AV-100, describing the complete facilities and products of the Avionics Division of the Company. Products covered by this publication include static time dalays, standard time delays, missile fuzes and programmers, flashers, voltage and frequency sensors, meter relays, power supplies and inverters, automatic check-out equipment and specialty devices. Included also are descriptions of the application of these products in complete systems developed by the Electronic Specialty Co. Typical systems included are Miss-Distance Indicator, Terrain Clearance System, Zero Delay Radar Augmenter, Proximity Fuze, Command Guidance Receiver, Word Warning, Coded Flasher, Autopilot, Aircraft Electrical Supply Sensor and Controller, and Flight Control System analyzer.
Circle No. 211 on Subscribor Service Cord.

DIODE CATALOG. A four-page catalog on silicon glass diodes is now available from Silicon Transistor Corp., manufacturer of silicon diodes and power transistors. The two-color spec sheet lists some of tha firm's high reliability general purpose and fast switching diodes and includes curves, charts and other pertinent data.
Circle No. 212 on Subscriber Service Card.

BROCHURE. Capabilities for tha isolation and reproduction of a wide variety of environmental characteristics are described in a new brochure entitled Environmental Facilities, publishad by the Missile and Space Vehicle Department of the General Electric Company. Reproducible environments discussed in tha brochure include conditions of vibration, with varying temperatures and eltitudes; humidity; tension and compression; shock; acoustics; acceleration; and pressure. Also described are chambers designed to simulate natural conditions of rain, sunshine, sand, salt spray, and fungus culture.
Circle No. 213 on Subscribor Service Cord.

GYROS. The new four-page, two-c brochures—one on floatad frae g and one on rate gyros—ara now a abla from Daystrom Pacific. Explod view, airbrush drawings show typ gyro designs. Major dasign features application advantages are pointad Complete specifications are providad two series of free gyros, FC35, FC45, and for ona series of rate g R-51.
Circle No. 214 on Subscribor Service

FASTENERS. A technical file folde cluding a new MS conversion table fasteners has just been released by Century Fastener Corporation. folder attempts to answer all quest pertaining to pracision, accuracy dependabla service for screws, b stop-nuts and special screw req ments.
Circle No. 215 on Subscribor Service

POWER SUPPLIES. The Electronic search Associates, Inc., announces availability of a four-page catalog w describes their Magitran line of state regulated power supplies. T supplies combine the features of r netic and transistor regulators, and many novel features not presently a able in conventional designs. The log sheet provides information several new intermediate current u as well as new specification data high current models. The catalog s provides full descriptive mat graphs, specifications, physical data related information.
Circle No. 216 on Subscribor Service

COMPUTERS. A 6-page illustr bulletin describing the new G-15 di computer with particular emphasis the magazine-loaded photo tape ra is offered by the Bendix Computer Also included are descriptions of PC and INTERCOM 1000 programming tems; accessory punched card, magr tape and paper tape equipment; eral special purpose devices and specifications. Copies will be mailed request.
Circle No. 217 on Subscribor Service

MAGNESIUM HYDRIDE. Immed availability of a new technical bul on magnesium hydride is announced The Dow Chemical Company. The page manual includes a general cussion of the metal hydrides with tions covering properties, reactions, and handling precautions for ma sium hydride. The unusual combina of properties in magnesium hyd suggests a wide range of uses such Captive hydrogen for foaming; a hydrogen for drying operations source of highly reactive magnesiu source of readily released hydroge reducing agent; energy for propel or explosives; a polymerization cat

"The next voice you hear..."

Tomorrow—or the day after tomorrow—we'll hear ›ices from the remote reaches of space. They will travel ver electronic highways that span interplanetary dis-nces in a matter of seconds.

Hoffman has been a leader in modern communica-›ns since electronics moved from the primitive stage simple entertainment radio to become a major tool science, industry, and defense. And probing into the ecrets of space affords the scientists and engineers at offman exciting new areas for exploration.

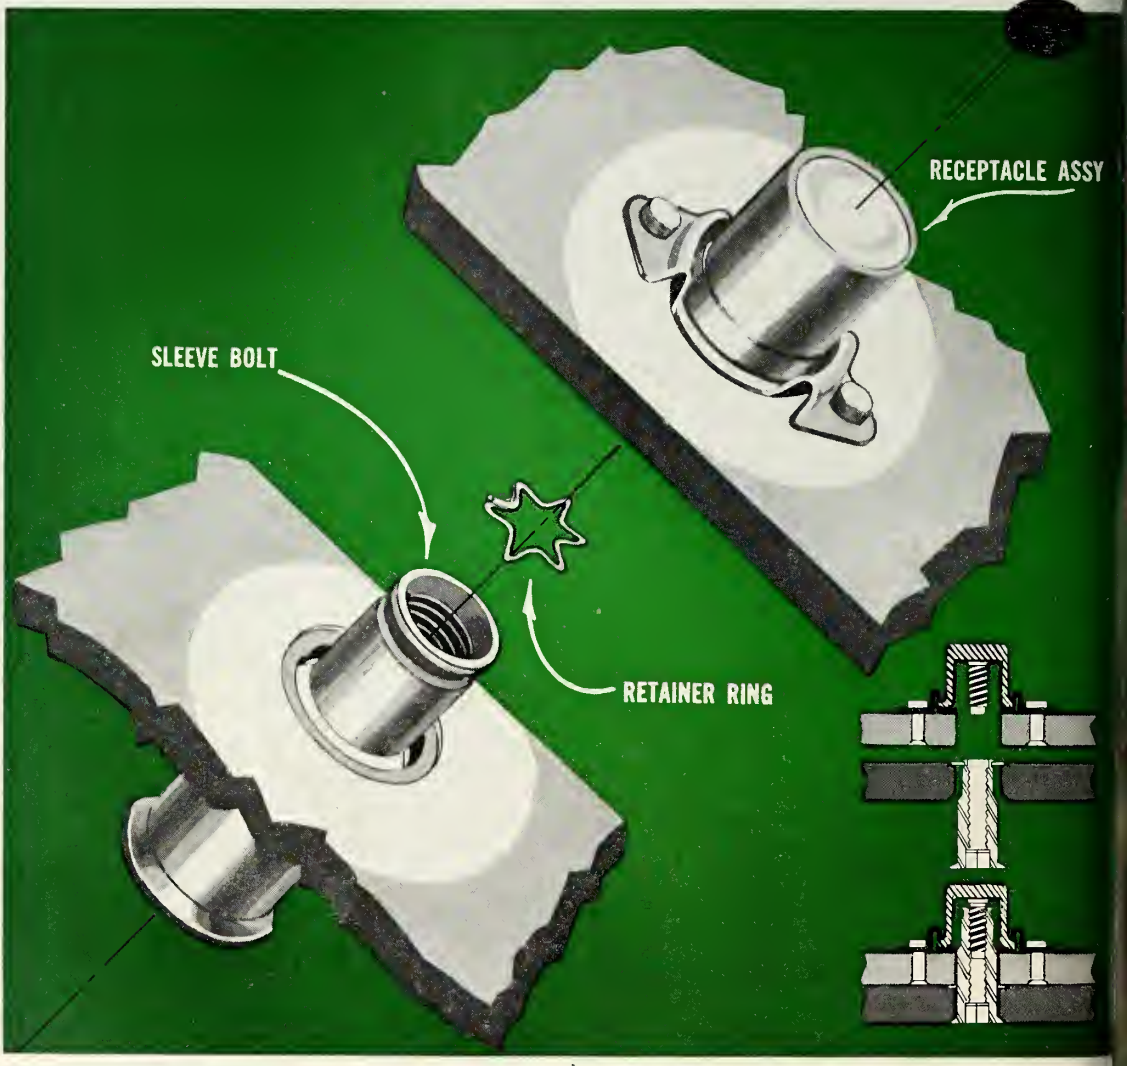
To meet these challenges, Hoffman is broadening its capabilities to develop new techniques in space communications, such as:

METEOR BURST COMMUNICATIONS • FORWARD SCATTER TRANSMISSION • FREQUENCY SYNTHESIZERS • SELVOX • VLF COMMUNICATIONS SYSTEMS • SPECIAL PURPOSE TRANSMITTERS AND RECEIVERS • DATA LINK SYSTEMS

Communications problems in the conquest of space are being met *now* at Hoffman, where creative minds are helping to build the electronic future of America.

Hoffman Electronics CORPORATION ®

HOFFMAN LABORATORIES DIVISION / 3740 South Grand Avenue, Los Angeles 7, California



Missile Support Equipment • Radar • Communications • Electronic Countermeasures • Navigation
Solar Power Supplies • Electro-Mechanical Equipment • Weapons Systems • Field Services

Significant developments at Hoffman have created positions for scientists and engineers of high calibre. Please address inquiries to Vice President, Engineering.

EVER INSTALL AN ACCESS PANEL WITH HOLES MISALIGNED as much as .040 in.?

Nutt-Shel's structural panel fastener closes gaps between panel and structure up to .125 in. *even when holes are misaligned as much as .040 in.*

In just a few turns the self locking, self jacking sleeve bolt is installed or removed. No special tools or instructions required. Construction is foolproof. Only four parts; nothing to adjust.

This high strength fastener, 4500 lbs. tensile and 13,000 lbs. double shear, has a deep hex recess for faster power driving and high preload. The fail-safe shear groove in sleeve bolt prevents over torquing.

Only one common hole size for panel and substructure Sleeve bolt is retained near flush, for easy removal of highly curved panels. Receptacle and sleeve bolt are readily replaceable. Self draining receptacle prevents moisture accumulation.

STYLES

Standard and self sealing types. Two-lug and corner-floating receptacle styles. Made in alloy steel for temperatures to 550° F. and in corrosion resistant steel for 700° F. service.

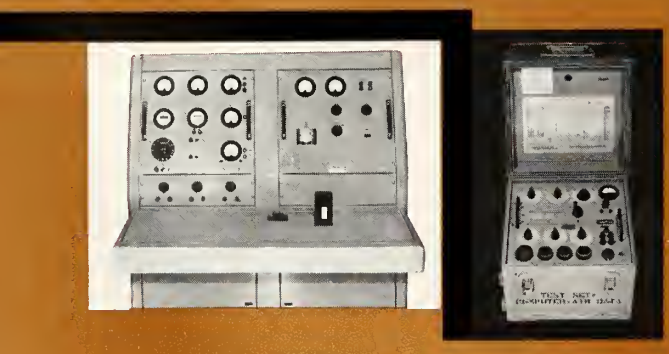
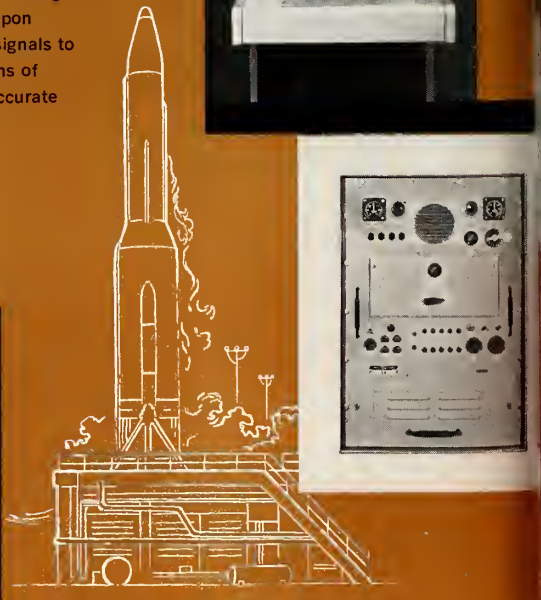
TEST EQUIPMENT CAPABILITY...from SMI



On flight lines and at missile launching sites...in production plants and depot maintenance centers...wherever speed and precision are vital, SMI test equipment capability meets the need with new levels of utility, repeatability...resolution...accuracy.



The SMI line of test equipment ranges from small, portable units that test single functions to console models that test complex airborne and missile electro-mechanical and electronic systems. Included in the line are pressure generation devices capable of generating static, differential and total pressures to simulate conditions from 1000 feet below sea level to 80,000 feet at speeds to Mach 5.

For example, SMI's TS 539 Air Data Computer Test Set is used for checking out elements of the Hughes Aircraft Company MA-1 aircraft and weapon control system. The TS 539 provides both electrical and pneumatic signals to the computer under test, achieving extremely high accuracy by means of electronically controlled force balance sensors. Mach readings are accurate to .7 millimachs and altitude readings within 15 feet at a speed of 1.4 Mach and an altitude of 30,000 feet.

Write today for further information on the TS 539 Air Data Computer Test Set and for details on SMI capability in test equipment.

Engineers: Investigate the opportunities available now at SMI in the fields of aircraft and missile instrument-control systems development.

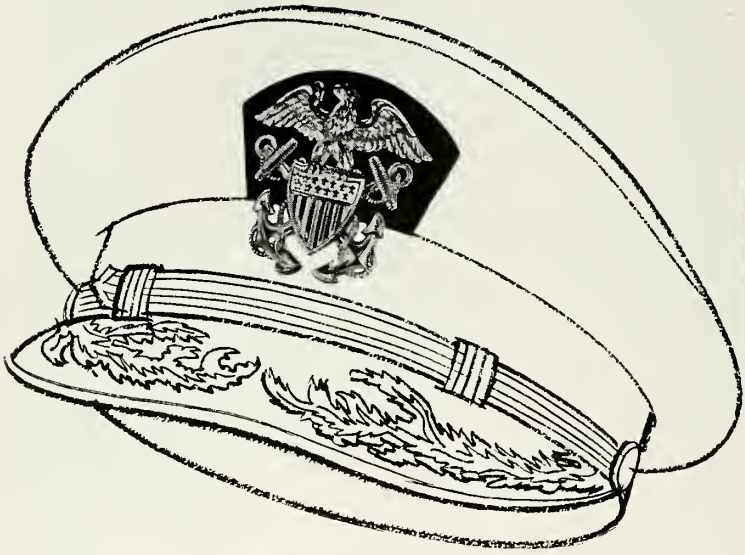
WESTERN GEAR CAN SUPPLY THE SOLUTIONS



PRECISION PRODUCTS DIVISION

To insure the reliability of the missile, its positioning must be accurately and cautiously handled. No matter what mode of transportation, truck, rail, air or water, there are Western Gear precision drives and related equipment engaged in the touchy and delicate task of handling the mighty "birds." Moreover, Western Gear's extensive experience and facilities enable the company to effectively handle your system requirements.

For complete information on our capabilities and facilities, write on your letterhead for Bulletin 5900.

EAGLE

...an advanced system program for better professional personnel

As the symbol of our Navy's air-to-air advanced weapon system concept, the Eagle presents a new challenge to senior professional personnel in technical and management fields.

Bendix Aviation Corporation will develop the Eagle long-range missile system. The Bendix Systems Division of Ann Arbor, Michigan with laboratories also in Van Nuys, California holds the prime system management and engineering responsibility.

Specifically, Bendix Systems Division has opportunities for the following personnel in Michigan and California—project supervisors and engineers in:

- **missile guidance and control**
- **weights and aerodynamics**
- **airborne radar and computers**
- **countermeasures**
- **displays and human factors**
- **systems analysis**

Working with top men in these fields at Bendix Systems Division, you will find conditions ideal for personal achievement and pleasant living. If you are interested and qualified, please write Bendix Systems Division, Department K7-27, Ann Arbor, Michigan, or Van Nuys, California.

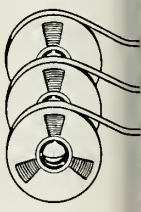
USE LOTS OF TAPE?

"SCOTCH" BRAND Instrumentation Tapes cut operating costs

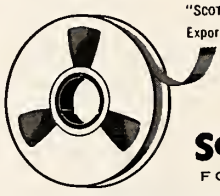


Let's develop our own small theory of relativit
For everything's relative, after all—even econom
Clearly, an economy effected now and *correcte*
later is no economy at all. In instrumentation tap
there's only one genuine economy—reliable pe
formance. And in performance, the last two wor
for any acute tape-user are "SCOTCH" BRAND.

First to last, "SCOTCH" BRAND Magnetic Tap
offer uniformity and reliability—born of the e
perienced 3M technology that created the first pra
tical magnetic tape and continues to advance tl
art of tape-making day by day.

But let's look at economy from another viewpoi
—in terms of some things around the periphery th
might not come so readily to mind—storage, us
waste, and time saved.

What other kind of record is so permanent it ma
last a lifetime, yet requires so little space for sto
age? Three reels of "SCOTCH" BRAND like those at the right "contain" 30 million characters. What other medium serves input, output and memory functions at such high speeds? Accepts both digital and analogue data?



What other kind of record is not *consumed,* even when it is used? "SCOTCH" BRAND Magnetic Tape is run and rerun for analysis, eras
and used again, permits retaping with correction
editing and new data.

Last, but far from least—in these days when tim
is money, what other medium speeds up data acqu
sition, reduction and control programming in
way that keeps critical projects rushing forward
full tilt? Or cuts production lead time and huma
error to a point where a 1000% saving may b
realized?

At any cost, "SCOTCH" BRAND Magnetic Tap
would be a good buy. And in every applicatio
"SCOTCH" BRAND Tapes offer that greater econom
—reliability. "SCOTCH" BRAND High Resolutio
Tapes 158 and 159 let you pack more bits per incl
offer extra play reels. "SCOTCH" BRAND Sandwic
Tapes 188 and 189 end rub-off, build-up, cut hea
wear to an absolute minimum, show little wear i
50,000 computer passes. "SCOTCH" BRAND Hig
Output Tape 128 offers top output at low frequer
cies, even under ambient temperature extreme
"SCOTCH" BRAND Instrumentation Tapes 108 an
109 offer top performance at lowest cost.

Where there's no margin for error, there's n
tape like "SCOTCH" BRAND Magnetic Instrumenta
tion Tape. For details, write Magnetic Product

IN THE PENTAGON

The budget squeeze for FY 1961 . . .
is already on for military and space planners. The Administration has passed the word that budgets are tentatively to be cut 10%. This would mean an across-the-board slash of more than $4 billion in the face of rising costs.

• • •

Problems with Convair's *Atlas* . . .
are believed to have been licked with the successful firing of a production model from Cape Canaveral July 21 and recovery for the first time of an *Atlas* nose-cone. But the first operational firing from Vandenberg AFB is still not expected before September. The Air Force wants to fire a few more of the big birds from Canaveral to make sure the cause of recent failures has been licked for good.

• • •

No new development . . .
resulting from production is believed to have caused the series of *Atlas* failures. Officials believe the cause was built into earlier models but failed to show up until recently.

• • •

A new hand is at the controls . . .
of the Pentagon's influentially-placed Ballistic Missile Committee. Deputy Defense Director Thomas Gates has taken over the committee's chairmanship. Ex-Missile Czar William Holaday formerly held the post.

• • •

Some code names . . .
for current ARPA projects to keep in mind:

. . . *Suzano*—A study program for a space platform to provide an advance base for space missions.

. . . *Principia*—An R&D program aimed at obtaining a solid propellant with a 10 to 20% greater specific impulse than any now known.

. . . *Pontus*—An R&D program aimed at obtaining a major improvement in structural and power conversion materials.

. . . *Tribe*—An R&D program aimed at obtaining a family of advanced military space vehicles.

. . . *Longsight*—Continuing studies of possible advanced projects including "unorthodox and creative" proposals.

ON CAPITOL HILL

The Hébert Subcommittee staff . . .
is still digging through a mountain of questionnaires from ex-military officers employed by defense contractors. Meantime, the subcommittee is expected to turn during the week of July 27 to looking into defense contractor associations.

• • •

First Air Force, then Navy . . .
is the order in which top military missile men are expected to testify at the House Space Committee inquiry into recent **Convair** *Atlas* and **Lockheed** *Polaris* failures. The hearings were called to find out whether the U.S. missile program is slipping.

AT NASA

Recent launching failures . . .
have hurt NASA's space research program. NASA did not plan for so many failures in its budget estimates. Now there is a lack of vehicles for some back-up shots.

• • •

NASA plans to bombard . . .
space with five satellites between now and the end of August. The space agency's accelerated launch schedule includes the last *Vanguard*, an *Explorer* balloon experiment, *Thor Ables III* & *IV*, and *Atlas Able IV*.

AROUND TOWN

Some of the reports . . .
that are being passed as the "latest" in the nation's capital:

. . . **Martin** *Matadors*—nuclear warhead-packing airbreathers—are being installed on Okinawa.

. . . It's possible that Russia may have a missile-launching nuclear submarine about the same time or not much later than the *Polaris* submarine will be operational.

. . . Russia has a good chance to have more than a dozen operational ICBM's in the hands of troops before *Atlas* is operational.

EXPANDING THE FRONTIERS

OF SPACE TECHNOLOGY...IN

QUALITY ASSURANCE

Quality assurance at Lockheed parallels in importance and augments the research and development, projects and manufacturing organizations. Quality assurance engineers establish audit points, determine functional test gear, write procedures and perform related tests.

These activities, supported by laboratories, data analysis, establishment of standards, and issuance of reports, all insure that Lockheed products meet or surpass contractural requirements. Economy and quality are maintained at every stage to produce the best products at the least cost. As systems manager for such major projects as the Navy POLARIS FBM; DISCOVERER SATELLITE; Army KINGFISHER; and Air Force Q-5 and X-7, quality assurance at Lockheed Missiles and Space Division has an important place in the nation's defense.

Engineers and Scientists—If you are experienced in quality assurance, reliability, or related work, you are invited to share in the future of a company that has an outstanding record of achievement and make an important individual contribution to your nation's progress in the race for space. Write: Research and Development Staff, Dept. G-4-29, 962 West El Camino Real, Sunnyvale, California. U.S. citizenship required.

Lockheed / **MISSILES AND SPACE DIVISION**

Systems Manager for Navy POLARIS FBM, DISCOVERER SATELLITE

Industry Countdown

STRUCTURES

Major review of Air Force . . .

weapon system management is under way. Big question before Air Staff is whether AF has delegated too much authority to prime weapons system contractors. Officials are looking into criticism leveled at the failure to develop in advance major components and subsystems which delay delivery of weapon.

• • •

Stronger bid for missile . . .

business can be expected from **Ryan Aeronautical** with forthcoming corporate shift. Key change: Edward G. Uhl, who has resigned as vice president of **The Martin Co.,** probably will be joining Ryan shortly as senior vice president. His resignation has been kept quiet up until now. Uhl has been succeeded as Martin-Orlando general manager by G. T. Willey.

• • •

Unless major engineering . . .

problem is licked, hardened ICBM bases will be much more costly than anticipated. Each missile launching pad will require a horizontal underground tunnel 100 feet in length to furnish orientation line for inertial guidance checkout. Elevator systems alone as yet cannot provide the critical tolerances required for positioning the bird in exactly the same space position when lowered and raised. Base line is needed for perfect guidance checkout before firing.

• • •

More construction . . .

problems are posed in ICBM installations by requirement of each missile unit for fixed reference target to align the bird. Material must have equal coefficient of expansion. Reference target cannot settle, must be perfectly rigid and still withstand climatic changes.

• • •

Even wood is finding missile . . .

applications. Some dummy mockups of **Lockheed** *Polaris* are of redwood and are being used to check handling and launching "pop up" gear. One advantage—the dummies float.

• • •

Look for Navy to . . .

start stressing new tactical requirements for *Bullpup.* Missile will be operational with Atlantic fleet this month. Already operational with Pacific fleet squadrons, the air-to-surface weapon is being designed for a 5-year service life.

• • •

'Cold and slow' missile . . .

proposal of **Radiation Inc.** is attracting interest for its biological warfare possibilities. In sharp contrast to the fast and hot missiles being stressed today, this 10-foot "Sprayer" missile would use a slow-burning propellant—probably black powder—to travel at the speed of an old-time Piper Cub. From a low altitude it would spray wide areas of dense undergrowth inaccessible to aircraft and where helicopter operation would be too costly. Fuselage probably would be of cheap material like hard cardboard. Government medical services are looking into this one . . . Radiation also has proposal for moon base environmental simulator that would sustain crew of three for about a month.

PROPULSION

Hydrogen-oxygen rocket . . .

test stand at **Pratt & Whitney's** Florida facility is getting a good workout with full-scale 15,000 pound-thrust *Centaur* engine. Engine is being tested in horizontal facility before being moved to vertical site. Company reports good results—which might mean engine will be available before the vehicle which is expected in 1961.

• • •

One to watch . . .

U.S. Rubber Co. is now actively researching synthetic rubber and plastic-based solid fuels at a new laboratory in Naugatuck, Conn. The work is company-funded . . . Missile activity is picking up in Connecticut (see p. 14).

• • •

Gabriel Co. is building . . .

$1 million propellant plant at Mesa, Ariz., to load thrustors and other devices for its subsidiary, **Talco Engineering,** maker of ejection seats and cable cutters. New Rocket Power Division will be headed by Charles E. Bartley, founder of **Grand Central Rocket Co.**

ELECTRONICS

Courier delayed-relay . . .

communications satellite work is moving ahead. ARPA has let contracts totalling almost $9 million to **Philco** (communications package); **ITT** (ground-based communications) and **Radiation Inc.** (ground-based antennas).

• • •

Gyroless gyro development . . .

of **Martin-Orlando** should stand industry on its ears when it is announced. Most of the system is proprietary, but this much is revealed: Martin has fired a small tactical missile twice successfully—without gyroscopes. System is good for short distances. Works on principle of mass suspension with the missile itself providing necessary rotation.

NAVIGATION AND GUIDANCE FOR MISSILES ▶

The management team of Nortronics Division of Northrop Corporation has more specific astro-inertial guidance experience than any other company in the free world. Here in one tightly knit organization are the men who created the state-of-the-art for airborne inertial guidance. The key management-scientist-engineer team who pioneered the Snark inertial navigation system in 1947 is still actively advancing the frontiers of this art. The most recent example of this is a breakthrough in 24-hour celestial tracking systems.

The list of accomplishments achieved over the past 13 years, if listed here, would more than fill this page. None of these achievements would have been possible without a dynamic, aggressive management group dedicated to producing the best product for the lowest cost – on schedule.

Missile scientists and engineers recognize Nortronics as a leader in the field of navigation and guidance. Nortronics' leadership has been accomplished by advanced research and development programs and years of production experience. These programs have resulted in state-of-the-art advancements in navigation systems which were considered visionary a short time ago.

Nortronics has today the solutions to tomorrow's missile guidance problems, the management and facilities to produce the systems required. The company's complete understanding of the military and technical requirements of missile systems qualifies Nortronics as the leading producer of tomorrow's most challenging astronertial guidance systems.

NORTRONICS
A Division of **NORTHROP CORPORATION**

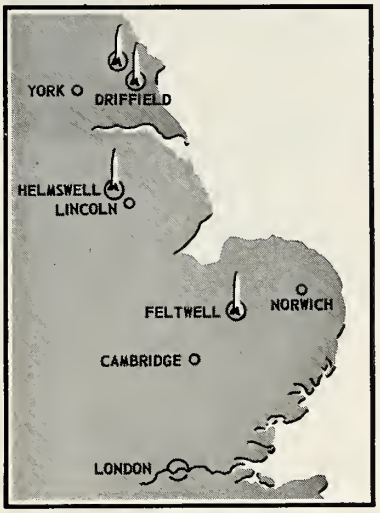
RAF *Thor* Base on 15-minute Alert

Western World's first ballistic missile site has had 400 simulated countdowns; double key arrangement gives Britain and U.S. joint nuclear control

by Clarke Newlon

FELTWELL BALLISTIC MISSILE BASE, ENGLAND—From a standing start, the Royal Air Force crews of this first operational ballistic missile base in the Free World today can fire its 15 nuclear-armed warheads at predetermined targets in just under 15 minutes.

More than 400 simulated countdowns of the **Douglas**-built *Thor* IRBM have brought the crews to this peak of efficiency, manned 24 hours a day, seven days a week as part of the deterrent force.



Feltwell became operational early in July. Farther to the north, along the east coast of Britain, Helmswell is expected to be operational in September, Driffield by December and a fourth unnamed base well before July, 1960, thus completing England's intermediate ballistic missile program.

Each base is of squadron strength—15 missiles. And each base consists of a main site and four satellite sites, each with three missiles. The maintenance and housekeeping facilities and personnel are at the main site. Feltwell has about 1000 RAF personnel who are responsible for command, operations, intelligence, communications, base support, safety and administration. Some 200 U.S. personnel, both military and civilian, have the responsibility for nuclear warhead storage, maintenance, technical supply and training. The main site and each satellite are separated by about 20 miles.

• **Vetoes and keys**—For the first time, officers of the RAF and USAF have a full explanation of both the "double veto" over the atomic bomb carried in aircraft from English bases and the similar "two key" arrangement for firing control of the *Thor*

The double veto as regards aircraft means that the British government must agree before nuclear bombs are actually carried in USAF aircraft from her bases; that also, Her Majesty's Government must concur before any nuclear bombs are dropped from planes which take off from her bases.

In the case of the double key for the *Thor* missiles, a comparable arrangement has been worked out. The commander at each site has one key. This must be turned to start the 15-minute countdown. The American officer at the site in charge of the atomic store has a second key. When the countdown has reached the point of minus three minutes, he must turn a second key before it can proceed further. And each U.S. site officer has a direct line to the Strategic Air Command Headquarters in Omaha which he can reach in 30 seconds.

BASE AT Feltwell is now operational. Three more will be added within a year.

Neither the double veto nor the double key precludes a delegation of authority by either side in a time of alert, when warnings were clear that an enemy was mobilizing for possible attack.

General Lauris Norstad, commander of SHAPE, incidentally, recently told newsmen that this double veto-double key arrangement which exists between Britain and France and which is being worked out with Italy, Turkey and Greece, is precisely the same agreement offered to France—and refused by Gen. De Gaulle.

• **The drill**—At Feltwell, the pilot *Thor* base, five crews of 16 men and two angry-looking guard dogs operate each site on an around-the-clock basis. The crews consist of one officer and six non-coms as launch crews; one U.S. officer with the second key, five police guards (and the two dogs); one fireman driver, one cook and one motor transport man.

Missiles for Feltwell are flown into nearby Lakenheath Airdrome, trucked over to the Receipt, Inspection and Maintenance (RIM) building at Feltwell where they are subjected to a complete checkout, and then sent to the sites. There the *Thors* are normally positioned horizontally under hangars on tracks. The three missiles are located 700 feet apart with the control van being roughly the fourth corner of the square. From this van, in a practice alert as they would in an actual firing, the countdown for all three missiles is controlled through five phases, as follows:

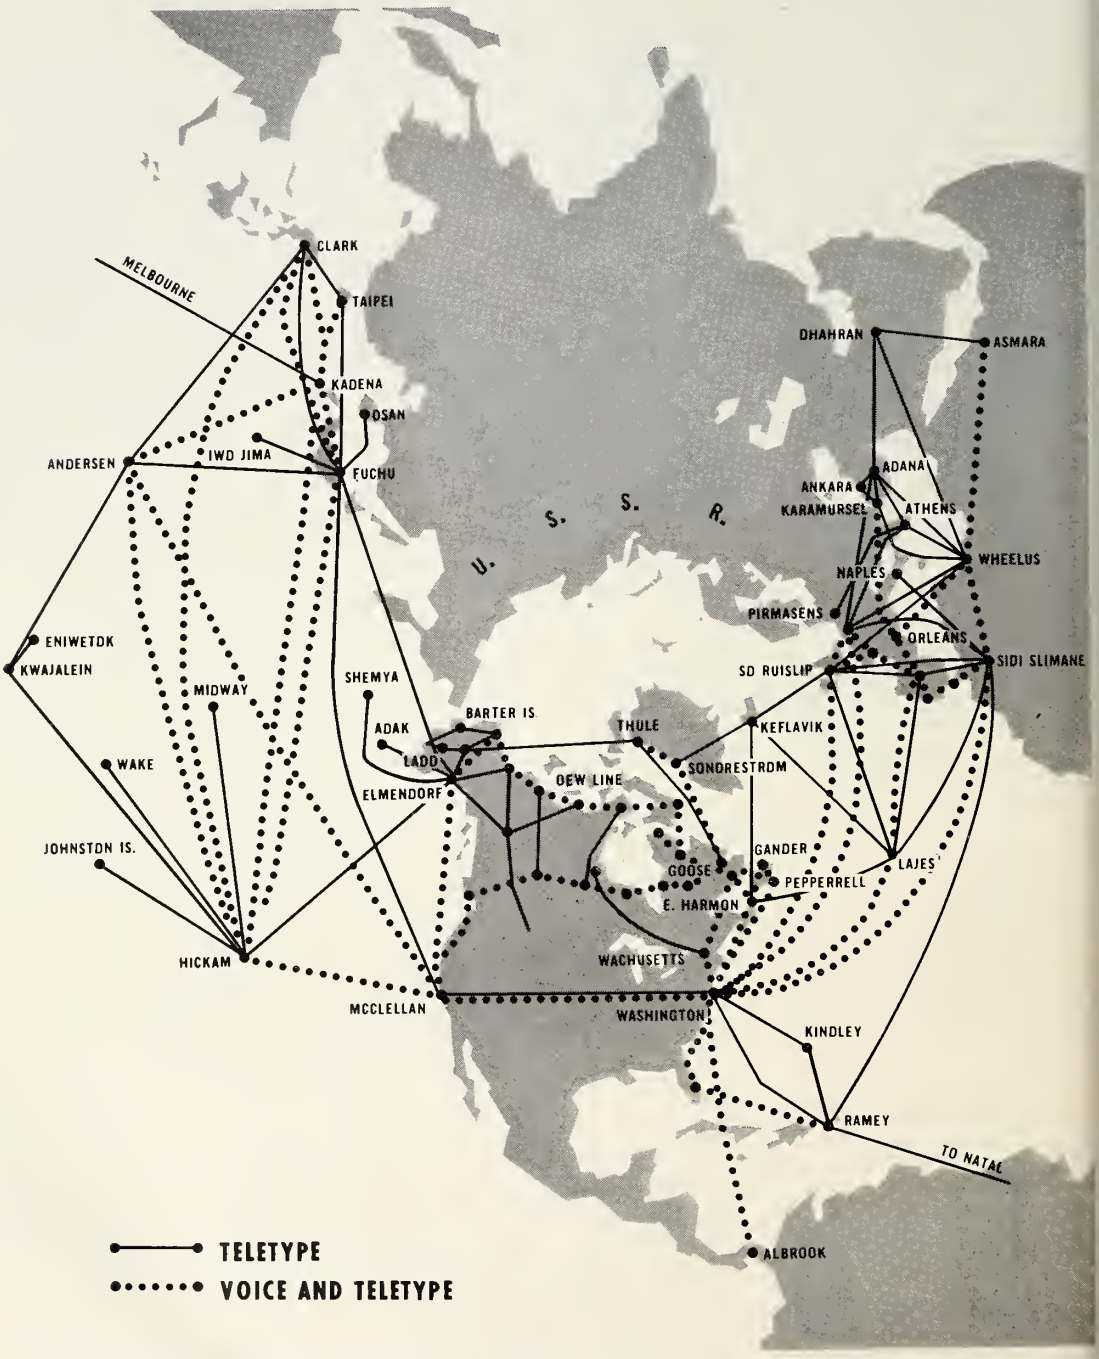
First: an automatic checkout of all equipment.

Second: retract cover hangar and raise missile.

Third: initial and slow propellant fueling.

Fourth: final and rapid fueling.

Fifth: missile disconnects from ground supply, own power takes over, engines ignite, missile fires.



Throughout this operation there are points at which the countdown can be held for times ranging from minutes to several hours, thus cutting down the reaction time during an alert. Through tying in with the NATO warning system, the RAF feels it would have 40 minutes warning time for a bomber attack, probably about seven minutes for a missile attack. The *Thor* countdown can be stopped at firing time minus three minutes if required.

• **U.S. aid**—While the *Thor* bases are almost completely an RAF operation, the U.S. lends a big helping hand. In addition to the U.S. Air Force personnel aiding training and maintenance, Maj. Gen. William H. Blanchard, commander of SAC's Third Air Division in England, estimated that approximately 1000 installation and checkout technicians from **Douglas, A. C. Spark Plug, Rocketdyne, General Electric** and other American companies were working on or near the missile bases, most of them living in trailers.

Of the personnel trained and being trained for the four RAF missile squad-

ssile Age

AF's vital communications network eventually will include satellites

by James Baar

WASHINGTON—A red phone sits in maha . . .

A baby-blue phone sits in Washgton . . .

The defense of the Free World ings on them. They are the key links the Air Force's 1.3-million mile mmunications network. Over these ould pass the word to unleash the ead power of SAC.

Today this means the U.S. bomber ets. Tomorrow the ICBM's.

The complications involved in buildg and maintaining such a communitions network are stupendous. And e complexity is growing greater as e ICBM enters the arsenals of the est and the East.

In order to meet the growing chalge, the Air Force is adding to its twork another 950,000 miles of comunication channels. Some of it will available in the very near future. l of it is scheduled to be operating thin two years.

Nor will this be the end.

The Air Force is looking for rapid velopment of communications satelles. These will help carry the increasig traffic load and insure still greater liability. They also will provide eans for reaching inaccessible areas such strategically vital zones as the ctic.

• **Heavy duties**—The Air Force mmunications system is designed to eet a number of specific difficult reirements. It must transmit such aphic information as maps and reconnaissance pictures. It must transmit pies of written material such as detled orders. It must transmit vast antities of data such as weather d flight information.

But most important of all to the curity of the Free World is that it nsmit verbal messages without fail the greatest possible speed. This is C's trigger.

To make this trigger work without l the Air Force communications net s been spread around the world from t United States like two great arms. e western terminus is Melbourne, stralia. The eastern, Dhahran, Saudi Arabia. Together they form a herculean "U" embracing the Soviet Eurasian heartland.

The entire multi-billion dollar system is designed to provide time. Time to get off the ground before you're hit. Time to determine that you're really under attack. Time to pull the trigger.

The missile is rapidly shrinking this time.

• **Command decision**—Today it would be a matter of hours. The DEW line across the top of North America would flash the warning of a bomber attack. NORAD and SAC would receive it simultaneously. An officer in the underground SAC command post at Omaha would raise the red phone. In less than a minute SAC planes around the earth would be ordered into the air.

As the SAC bombers moved toward their targets, the U.S. high command in Washington would have at least an hour and a half to decide whether World War III were on. But not much more. The bombers would be told to go in—or they would have to return.

Such a decision might well be made with only minutes to spare. Then the President, who alone has the authority to order the use of U.S. nuclear weapons, would give that order. An officer in the Pentagon command post would raise a baby-blue phone and speak the code word for "Go!"

Three years from now there will no longer be hours. There will be only minutes.

BMEWS, the **RCA** ballistic missile early warning system now under construction in Alaska and Greenland, would flash the warning to NORAD and SAC that hundreds of Soviet ICBM's had been launched.

There would then be 15 minutes before the ICBM's struck. All that formerly could be done in several hours would have to be done in this brief span. Plus a new task: Scores of U.S. ICBM crews along with the *Polaris* submarines then on station would be ordered to launch their missiles.

The Navy is developing an entirely new communications system designed to be capable for the first time of contacting submarines at great depth anywhere in the world's oceans. Huge towers are being built for the secret system at Cutler, Maine.

The exact method of tying the *Polaris* network into the rest of the nation's deterrent force is still to be determined at the highest military levels.

• **Meeting the challenge**—The unrelenting requirements for a communications net capable of triggering so vast a force in so short a time are staggering. There can be no delay. And its reliability must be nearly 100%. Ninety-nine percent is not good enough. Such a system would fail 14.4 minutes a day—virtually all the warning time BMEWS will be able to give.

The Air Force has been rapidly revamping its communications system because of this Missile Age challenge.

At present, 948,000 channel miles of the Air Force net are the old high frequency channels. These can be jammed and are highly sensitive to sun spots. And they have had to be duplicated many times in order to ensure the high reliability required.

However, the Air Force already has 325,000 channel miles of network based on the superior tropospheric scatter system. And the 950,000 more miles under construction are of the same type.

The troposcatter system is all but unjammable. It provides an extremely wide band of 132 channels. And it has 99.99% reliability.

The system operates by bouncing powerful signals off the troposphere from one relay station to another. The stations are up to 600 miles apart.

At the same time, many of the hundreds of thousands of channel miles of commercial lines and cables available to the Air Force on a full-time basis are being hardened and routed around target areas.

Finally, the Air Force has available in case of national emergency the use of Army and Navy facilities.

All of it is geared to one overriding goal: A guarantee that if some day someone has to reach for the red and the baby-blue phones the codeword for "Go!" will be heard around the earth.

Third of A Series

Missiles Fill Gap in Connecticut

Nutmeg State reaps better than $500 million a year from missile/space work employing about 100,000 and taking up slack caused by other defense cuts

by William E. Howard

HARTFORD—On July 2, 1957, three months before *Sputnik* galvanized the Free World, a team of eight Connecticut manufacturers approached the Springfield (Mass.) Ordnance District. Objective: a contract to develop and produce an entire missile system.

The mission failed. But the foresighted action nevertheless marked the beginning of a major new industry in the Nutmeg State—nearly every member of the team has since become heavily engaged in missile/space work.

Today, although the state still does not have a prime missile contractor, manufacture of highly specialized missile components and support equipment is a mushrooming business. Humming factories are turning out a big percentage of the bearings, springs, castings, gaskets and cams, as well as the more "exotic" items—like nose cones, mixing equipment for solid fuels and infrared guidance packages —that go into virtually every missile system in the nation's arsenal.

The total number of companies directly engaged in missile work was placed in 1958 by the Connecticut Development Commission at more than 220. These firms employ 83,000 on production lines and another 27,000 scientists and technicians. Some 358 research and development firms employ an additional 12,000—with much of their effort related to the new space technology.

Actually, the CDC figure may be considerably outdated. The Pratt & Whitney Division of United Aircraft, which is in the process of organizing to become a prime systems contractor, now has more than 1400 of its 6600 suppliers in the state. By year's end, P&W expects the Connecticut total to increase to 2000. Avco's Lycoming Division has more than 500 firms in the state which are suppliers or subcontractors. And the Electric Boat Division of General Dynamics, producer of *Polaris* fleet ballistic missile nuclear submarines, had another 123 at last count. Many of these suppliers sell to more than one of the bigger contractors—inside as well as outside the state.

Arriving at a dollar volume for the state's missile industry is virtually impossible, because of the multitude of small contracts and purchases conducted entirely within the industry. But basic contracts indicate that missile manufacturing is running at well over a $500 million annual rate.

• **Missile transition**—Industry experts note that Connecticut is in a period of transition brought on by the phase-in of missiles and a cutback in aircraft production and other military weapons long made here. The spurt in missile component manufacture appears to be offsetting this loss of other defense business.

The Connecticut Labor Department reports that aircraft and parts employment centered in Hartford, Bridgeport and New Haven was 60,000 in May—6000 less than the same month a year ago. However, total manufacturing employment is even with last year—at about 400,000 statewide.

Connecticut, along with other New England states, also has lost much of its textile industry in the migration to the South. As a result, despite the expanding national economy, the state is just about holding its own wh industry is on the increase elsewhe

Accordingly, state officials a lustily beating the drum to attr new industry.

Gov. Abraham Ribicoff journey to the West Coast a month ago a at a luncheon arranged by the Co necticut Development Commission San Francisco for a group of Nort ern California industrialists, he sai "Connecticut has the most to offer a industry planning to establish an E Coast branch."

Apparently in deference to t tussle between New York and Ca fornia lawmakers over geographic placement of defense contrac Ribicoff hastily added:

"I want to make it crystal cle that . . . we are not here on any i dustry raid. We are not asking an one to pack up and move to Conne ticut. However, a community of i

ANECHOIC chamber at CBS Labor tories, Stamford, used for quantitati checks.

XAMPLE of inter-industry cooperation in Connecticut is use of ultrasonic resonance gage developed by Branson Instruments, ic., of Stamford, to test wall thickness of *Nike-Hercules* nose cones built by Avco's Lycoming Division, Stratford.

rest exists already between our two ates . . ."

• **Alarm at DOD cut**—One Congressman, Rep. Frank Kowalski (D-onn.) is frankly alarmed at an apparent sharp cut in defense orders ping into the state. In his home town Meriden, Kowalski says, there are 500 unemployed defense workers. Moreover, he has compiled figures hich show that Connecticut has pped from $1.2 billion in defense ntracts—7.5% of the 1956 defense dget—to $897 million, or 4.3%, in 958.

He expects the state's share of the fense dollar this year to be even less about $500 million.

"This means a shift of 40,000 jobs t of the state," Kowalski told M/R. am against this kind of whipsawing, th the defense industry shifting to alifornia for two years and then ifting back. It is jerking the hell out our economy."

Kowalski says DOD should strive create more stability of the day-day variety in defense manufacture. nd he adds, "Maybe we need a ecial agency to plan for the *present*."

The lawmaker concedes, however, at missile component manufacture is king up the slack and that the reduction in defense contract dollar lume may not tell the whole story. The difficulty is, though, you can't ally determine just where we stand," said.

• **UA missile build-up**—At the oment the volume of missile busiss shows every indication of continuing to boom. Here's what is happening around Connecticut:

United Aircraft President William P. Gwinn two weeks ago announced that the company will spend $68 million to expand and modernize production and experimental facilities to handle its bigger role in missile/space work. All four operating divisions—P&W, Hamilton Standard, Sikorsky and Norden—are being geared to bid as a prime systems contractor.

Several thousand of UA's more than 45,000 employes are involved in missile manufacturing operations. There are 10,000 in P&W engineering sections.

Heading UA's Missiles & Space Systems Division, which was formed a year ago and is now working up steam, is aircraft propulsion wizard Wright A. (Parky) Parkins. His 200-man engineering division at East Hartford is making weapon and space proposals and has "several" classified contracts under negotiation.

"We are hopeful this will grow into a real program and Connecticut will benefit in a large way," says Parkins. He explains that the overall plan will see P&W, which now builds *Hound Dog* J-52, and *Snark* J-57 engines, providing both liquid and solid rocket propulsion systems; Hamilton-Standard—controls, air conditioners and other accessories; Sikorsky—airframes, and Norden—electronics and guidance.

UA's United Research Corp. at Menlo Park, Calif., is actively pursuing propellant research, on both a long- and short-range basis. Parkins told M/R UCR is setting up a multi-million dollar facility for solids development. The effort is strictly R&D and production will be handled by P&W in Connecticut.

P&W right now is developing rocket cases of titanium and steel in a "cold-flo" turning process. These are second- and third-stage cases for *Minuteman, Pershing* and *Polaris* under sub-contracts with Aerojet-General, Thiokol, the Navy's BuOrd, and Hercules Powder.

At Middletown, UA has 1500 employes in the Connecticut Aircraft Nuclear Engine Laboratory. CANEL is a "hot lab" owned by the Air Force and has been in operation since 1950. Various other engineering sections of UA also are working on advanced propulsion systems—ion, plasma, solar—and lead boundary layer devices.

• **Norden consolidation**—Norden-Ketay, acquired by UA a year ago, is in the process of being brought under one roof. Facilities at Stamford, Milford and White Plains, N.Y. may be moved to a new plant at Norwalk, Conn., although no site has been picked yet. The division's 2300 employes are turning out gyros, synchros, analog-to-digital converters, pressure ratio transmitters and indicators, gas pressure systems, servo motors, resolvers and other components. These parts all have been designed specially for *Atlas, Polaris, Thor, Nike, Terrier, Tartar, Redstone, Jupiter, Talos, Bomarc, Regulus, Snark, Hound Dog, Tall Tom* and *Swallow* missiles.

The Hamilton-Standard Division, which was hit by a curtailment in aircraft propeller demand, is making a comeback in the missile controls area and now employs 7000. H-S officials are excited by a new "Min-IR-Cooler" for IR detection and satellite applications which was developed with Arthur D. Little, Cambridge, Mass. The division is producing auxiliary power

emphasis on cooperation . . .

packs and is on the Boeing team to make environmental controls for the global boost-glide *Dyna-Soar* space vehicle.

Leaning back in a chair in a paneled office once occupied by aircraft pioneer Chance Vought, Parkins observed recently that the Missiles & Space Systems Divisions real job is to "unite and exploit the capabilities already in UA—and we're on the spoor."

MSS, incidentally, is not tied to UA's other operating divisions in putting together a missile/space system. "We're free to go," says Parkins, "anywhere we can find a better mousetrap."

• **Big Avco contract**—Avco's Lycoming Division at Stratford is the production arm of the company's big R&D laboratory at Wilmington, Mass., along Boston's "Golden Industrial Semicircle." It also has outside contracts. Just three weeks ago, Aerojet-General signed the division to a $6 million order for second and third rocket chambers for *Minuteman* and *Polaris*. The unit's 3700 employes also are busy producing *Titan* and *Minuteman* re-entry vehicles, *Nike-Hercules* nose cones and the forward diffuser for the Bendix *Talos* surface-to-air missile.

In 1958, Avco-Lycoming had 1750 suppliers to whom it paid $12.3 million. Some 500 of them were in Connecticut and received $4 million. The company says there will be a "lot more" this year.

It was H. Webster Crum of Avco-Lycoming who spelled out the proposal of the eight Connecticut manufacturers to the Springfield Ordnance District just two years ago. Others joining in the now-famous "Southern New England Missile Resources Group" were American Machine & Foundry, which has a substantial R&D laboratory of 1100 at Greenwich, Conn., Kaman Aircraft—now working on highly classified *Polaris* electronic countermeasures; Electric Boat, Landers Frary & Clark—now making small rockets; Norden-Ketay, Manning Maxwell and Moore Inc., Stratford—researching high pressure/high temperature and controls for chemicals, power and other applications, and Sperry Products, Inc.—electronics and data processing.

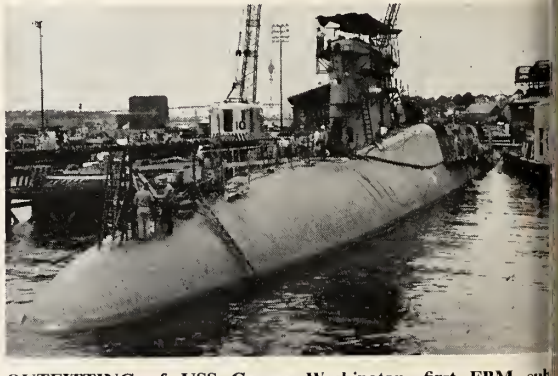
• **EB payroll $60 million**—Electric Boat's huge shipyard at Groton is a beehive of activity in the big push to launch fleet ballistic missile submarines to carry the Lockheed *Polaris*. Some 10,000 employes—2000 of them commuters from Rhode Island—are hard at work on the 380-foot, 5600-ton Patrick Henry, sister ship to the first FBM sub, George Washington, which was launched June 9. (M/R June 8, p. 31.)

With a 1958 payroll of $60 million, the yard has contracts to build two more FBM subs, first of a new class. EB has on the ways two other revolutionary nuclear subs. They are the high-speed Triton, which has two reactors for propulsion, and the Tullibee —the nation's first atomic-powered "killer sub" for anti-submarine warfare.

All of the subs are costing around $100 million, and the Navy has provided more than $2 billion so far for the entire FBM program. EB, incidentally, says that through January, 55% of its direct purchase orders under the FBM program went to small business. These suppliers also received 38% of stock inventory dollar volume.

• **Wealth of specialties**—The multitude of small, growing firms which make up the fabric of Connecticut's missile industry produce products which read like a rocket hardware store. At Middletown you will find Safeway Heat Elements making heaters and heating pads; Hart Mfg. at Hartford turns out relays; Hi-G, Windsor Locks, is producing capacitors. Vickers Inc. Marine & Ordnance, a division of Machinery Hydraulics, is a ground handling and launching equipment fabricator.

In the Waterbury area, there is the Bristol Co., with 1400 employes producing high-speed relays and choppers at Danbury. Barden Ball Bearing makes miniature instrument bearings for missile applications, and Reeves Soundcraft, telemetry tapes and product control systems.



The Perkins-Elmer Corp., Norwalk, an old established company is in the missile business with tracking theodolites and infrared systems.

To test the wall thickness of Avco Lycoming's *Nike-Hercules* nose cones Branson Instruments Inc., Stamford has developed an ultrasonic resonance gage. These cones must be held to a variance factor of ±0.006 in. A new company ready to make itself available to other Connecticut missile men is Propulsion Test Facilities, New Haven, an affiliate of MB Mfg. Co. This firm offers complete environmental test facilities for checking component reliability under simulated space conditions.

The Rogers Corp., Rogers, supplies the duroid in the *Thor-Able* telemetry system, playing a small but important part in the recovery of the test missile's nose cone. The tiny 2-ounce motor which drove the miniature tape recorder in the *Vanguard II* weather satellite was made by the A. W. Haydon Division of Consolidated Electronics Industries Corp., Waterbury.

JET ENGINES for *Hound Dog* and *Snark* are turned out at Pratt & Whitney's Aircraft Division in East Hartford.

OUTFITTING of USS George Washington, first FBM submarine at EB, Groton. Sister ship is under construction.

Vehicle Requirements Are Tricky

A look at some of the myriad problems involved in designing mobile systems and an outline of some of the vehicle combinations that may be chosen.

by John J. MacRostie

SAN JOSE, CALIF.—One of the major problems in the testing and deployment of large missiles is transporting them over land.

Difficult obstacles must be overcome. Specialized support vehicles are needed to overcome them.

The Preliminary Design Department of **Food Machinery and Chemical Corp.'s Ordnance Division** has conducted extensive studies in order to meet this challenge. The results show the great complexity of the problems involved.

To begin with, in order for a missile system to be mobile there must be the capability of moving missiles from the launch area to another on short notice even during adverse weather conditions. Careful consideration must be given to the ground over which the equipment must travel.

Here are some of the possible terrain conditions:

- Good, hardtop roads exist between all possible launching sites, and there are *no* bridges nor underpasses with limited clearance.
- Good, hardtop roads exist between all possible launching sites, but there *are* bridges or underpasses with clearance limits.
- Good, hardtop roads exist over part of the area, but secondary dirt roads must be used in other parts. These secondary roads are good in dry weather, but will become muddy during prolonged use in rainy weather.
- Both hardtop and dirt roads exist in the area but the tactical situation demands that the equipment must at various times be moved over open country where no roads of any type exist. Under this general terrain situation, the ground may be hard-packed and will support the equipment during dry weather without excessive sinking, or sandy soil may exist causing high rolling resistance even during dry weather, or mud conditions may exist over most of the terrain during wet weather, creating extreme mobility problems.
- Good roads in the area, but during the winter (even in the southern U.S.) there may be snow conditions at certain times of the year.
- There are normally good roads available, but, due to man-made or climatic damage, the roads must be detoured in certain areas either via secondary dirt roads or via open field terrain.
- The slopes that exist in the area must be considered. If there is rolling terrain with severe grades, then greater tractive effort is required than would be required in flat areas.
- The final conditions to be considered is the width of the roads, radii of curves, and clearances at intersections. If the roads are narrow and meet at 90° intersections, then long trailers could not turn without going off the road, and if there are deep drainage ditches or other obstructions at these intersections, then, to insure adequate equipment maneuverability, a steerable trailer suspension must be provided.

In establishing an equipment mobility concept, each type of terrain mentioned above must be considered to determine whether that particular condition would be encountered in the area of missile system operation.

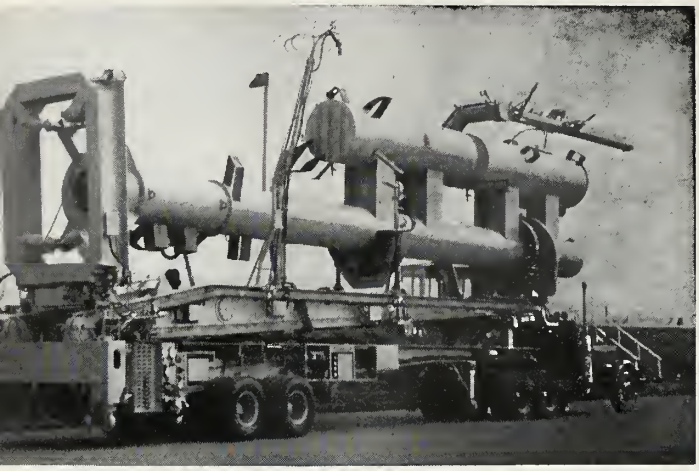
If it is known that good roads will exist at all times, it is not necessary to provide equipment with a high degree of cross-country capability (which will cost more and be more difficult to maintain than simple highway-trailer type equipment). If, on the other hand, difficult terrain must be traversed, even for short distances, cross-country mobility must be incorporated into the design.

However, if a high degree of mobility is required for only short periods, the mechanism may be designed for low-speed operation and relatively short life. Or, if a high degree of cross-country mobility is required for all normal use, then the feature must be incorporated for full-life usage and must be effective in all speed ranges.

- **Combinations**—Many mobile equipment concepts, embodying varying degrees of mobility, are possible. In each case the prime mover—tractor—is a critical item, and its size, power and tractive capability must be considered relative to the weight and rolling resistance of the trailed load.

Here is a brief list of some of the possible equipment combinations which apply to 50,000-pound payloads or 100,000-pound payloads:

- A *highway type* semitrailer and a military wheeled prime mover which would utilize standard tire pressure (in excess of 30 psi) for highway use.
- A *wheeled* semitrailer and a trac-



About the Author

John J. MacRostie is manager of the Preliminary Design Engineering Department of the Ordnance Division of Food Machinery and Chemical Corp. Before this assignment, he was Chief of Preliminary Design. In his nine years with FMC, MacRostie was an engineering group leader on the M-59 and T-93 vehicle programs and was project engineer in the Navaho missile support equipment program.

The FMC Ordnance Division has for over 17 years devoted much of its design and manufacturing capabilities to providing mobility for U.S. Armed Forces. It has done considerable work in the past four years in the area of wheeled transporters for large missile systems.

FMC, under a contract with North American Aviation, designed and manufactured the transporter erector launcher for the G26 Navaho, and subsequent to that designed the transporter erector launcher for the G38 Navaho and was actively engaged in that program at the conclusion of the overall Navaho program. In the field of IRBM's, FMC, under contract to Douglas, developed and manufactured the transporter erector launchers for the Thor system.

wide choice of equipment . . .

HEAVY equipment used by FMC's Ordnance Division was instrumented for shock testing during the company's work under the *Navaho* program.

tor; using large-diameter, off the road low-pressure (under 15 psi) tires on both the tractor and trailer.

• A wheeled semitrailer with a *tracked* prime mover. In this case, the tracked vehicle ground pressure would be less than 10 psi, and the trailer tire pressure would be under 15 psi.

• A wheeled semitrailer with *power-driven* wheels combined with either a wheeled or tracked prime mover which would supply power to all of the wheels. The trailer wheel drive would be used for *all* speed ranges, and the tire pressures again would be under 15 psi.

• A wheeled semitrailer similar to the above, but with power applied to the trailer wheels *only at speeds below 5 mph* to provide traction for difficult terrain. Above that speed, the wheels would be free-wheeling.

• A *track* type prime mover and a *tracked* semitrailer with power at the trailer track through all speed ranges.

• A tracked semitrailer similar to the above, but with power at the trailer track at speeds only below 5 mph.

Let us now consider the reasons that would cause us to use the various combinations.

• Standard highway tires (pressure over 30 psi) have large carrying capacities for a relatively small size. The small size is an advantage in keeping the vehicle width and height to a minimum, but if the vehicle is to go off the highway, small, high-pressure tires will be a severe disadvantage due to their small area of ground contact. For special usage, it is helpful to reduce tire pressure in the highway type tires —but tests have shown that for a specific tire diameter and load condition, reducing the pressure beyond a certain point will actually increase the rolling resistance in soft ground.

• Large-diameter, low-pressure tires offer low rolling resistance across soft terrain and thus afford good cross-country mobility. Their large size, however, means that the equipment must be considerably wider and higher. The wheels must be placed far apart to permit sufficient room between the tires to accommodate the payload—in this case, the missile. For large tires approximately 7 to 10 feet in diameter, stability considerations generally preclude placing the entire payload above the tires—hence the vehicle must accept increased width.

• **Aircraft problems**—This width factor is particularly critical when air transportability is required. The largest cargo aircraft today will accept a load 144″ wide—and load height is also a design factor.

To overcome this limitation, thought must be given to the possibility of disassembling equipment (in a short period of time and with simple tools) to reduce over-all package dimensions.

• **Track suspension?**—A tracked trailer might be used for this application. Although it is not a common trailer design concept, this type of vehicle has been manufactured in the past for the U.S. Army. It has several advantages, primarily in the area of low ground pressure for soft soil, sand, or mud.

A tracked suspension is available for static loads up to 120,000-pound load capacity (M-48 tank), and this capacity could be increased. The tracks could be placed entirely under the payload, since a 60-inch-high deck would clear the entire suspension, thus permitting a narrower overall vehicle width.

One objection to the track suspension is that compared to wheeled vehicles, it has a rather high rolling resistance on hard-surface roads. Here again the probable terrain must be considered.

In line with the tracked trailer idea, tracked prime movers must also be considered. A tracked vehicle will outperform a wheeled vehicle of the same weight and power over difficult terrain; if maximum drawbar pull per pound of dead weight of prime mover is required, tracked vehicles should be selected. Alternatively, if most of the trip is to be made at high speed (above 30 mph) and on hard-surface roads, wheeled vehicles should be considered.

• **Choice of drive**—Once a suspension has been selected, we must consider the drive mechanism. If the equipment is to traverse cross-country terrain, power should be provided to all wheels of the prime mover and trailer. Without power to all wheels, even large-diameter, low-pressure tires will provide only limited performance on soft ground, sand, or mud. Within the powered-wheel concept, there are two primary approaches:

• Power to the trailer wheels for all speed ranges.

• Power to the trailer wheels only for low speed (under 5 mph).

Before a drive method can be chosen, operational requirements of the trailer drive must be determined. Either the trailer drive will function through all speed ranges from 1 to 40 mph, or it will be used only for low speed, high-tractive-effort travel (below 5 mph).

In the latter case, it is assumed that: if the terrain is such that the tractor can pull the trailer at speeds above 5 mph, it doesn't need the help of the trailer wheel drive; terrain conditions requiring tractor drive at speeds under 5 mph will be limited; and time delay due to lower speed will not be a large portion of overall transport time.

The reason for offering this low-speed alternate is that, for speeds from 1 to 5 mph, no complex gear shifting is required, since either an electric or hydraulic motor can regulate speed internally in those ranges and still give good output efficiency. A greater range of self-regulation is possible, but unless the motor size is increased to give reasonable torque at high speed, some performance will be sacrificed at the high and low extremes of speed, if a 40-to-1 speed relation is required.

There are three basic methods of providing power to the trailer wheels:

1. Mechanical drive to a standard

ruck-type axle, with power supplied y either a separate engine on the ailer or a mechanical drive shaft rom the prime mover.

2. Electric motor drive for each heel, with power provided by a generator mounted on the prime mover.

3. Hydraulic or air motor drive for ach wheel, with power provided by hydraulic pump mounted on the rime mover.

• **Mechanical**—The mechanical rive has several disadvantages: The rive-shaft from the prime mover to the actor would require a very complex ower take-off coupling on the prime over, the drive shaft would be exssively long for the trailer length that required for this program, and the lative angle between the prime mover nd the trailer would be restrictive, verely limiting the maneuverability of e equipment. A separate engine on e trailer is rather redundant, since ime movers with adequate surplus wer for this requirement are availle. The problem is not power but nverting to useful tractive effort.

• **Electric**—An electric-motor drive r each wheel is now becoming quite mmon, at least in prototype equipent, and the state of the art is suffiently advanced to make this method actical. One disadvantage of the elec- c drive is the weight problem, since e generator and drive motors are relvely heavy items. On the other nd, performance of electric drives is cellent, affording a good range of rque-versus-speed performance, with e proper "gear range" being selected tomatically, and thus reducing the ver-skill requirement. Dynamic brak- reduces wear on friction-brake linrs and offers greater braking ability r prolonged periods of time during ended down-hill operation.

• **Hydraulic**—A hydraulic-motor ve for each wheel will offer performce somewhat similar to the electricotor drive, at least for low-speed opetion. In this system, vehicle speed is proportionate to pump output lume, and vehicle torque or pulling ver is proportionate to pump output ssure. At high speed, the volume of flow for large equipment would reire large-capacity pumps, valves, and ing. Therefore, there is a flow rate ond which it would *not* be econically feasible to operate, and this w rate would dictate the maximum icle speed.

If used in the speed range which is conomically feasible, the hydraulic ve may prove to be a lightweight em with performance comparable an electric drive.

• **Prime movers**—So far, we have ussed some of the factors to be sidered in arriving at an overall concept for the transporter-erector-launcher for a large mobile missile system. Now let us look at the problem of selecting a prime mover or tractor that will propel the unit.

The results of an FMC survey of prime movers resulted in the data presented on p. 20. Time did not permit an examination of all vehicles which may be available, but the broad cross section obtained was sufficient to establish a working base considering performance, physical characteristics, availability and cost.

Let us examine a hypothetical case involving a missile that weighs 75,000 pounds—midway between the 50,000 and 100,000-pound load discussed previously. These basic calculations will aid in selection of a prime mover:

G = Incline of Grade, in per cent
X = Coefficient of Rolling Friction
R_r = Rolling Resistance, in pounds
Θ = Horizontal Incline of Road, in degrees
W = Vehicle Weight, in pounds
U = Tire-adhesion Coefficient
R_g = Grade Resistance, in pounds
R_a = Air Resistance, in pounds
D = Drawbar Pull, in pounds

The following weight assumptions are made for this calculation:

Item	Weight
Missile	75,000 lbs.
Transporter-Erector-Launcher	45,000 lbs.
Sub total	120,000 lbs.

It is desirable in the case of a semitrailer to distribute the 120,000 lbs. so that approximately 1/3 is on the tractor's 5th wheel and 2/3 is on the trailer wheels. The semitrailer approach is favored for cross-country operation, since some of the towed weight can be put on the tractor to add to its draw bar capability.

Load Distribution

Item	Weight
Tractor 5th wheel load	40,000 lb.
Trailer running gear load	80,000 lb.

From the chart on p. 20 it can be seen that there are several tractors in the proper size area. (Assuming a 5000-pound overload is permissible, then a tractor with 35,000 pound rating is usable.)

Total Highway Load

Item	Weight
Missile & trailer	120,000 lb.
Tractor (Caterpillar DW-20)	29,000 lb.
Total	149,000 lb.

The vehicle required gradability performance must now be predicted. Below are some standards that can be applied:

Description	Grades "G" Maximum
Super Highway	6%
Mountain Highway	12%
Desired for our system	20%

(The 20% maximum grade was selected for our system as the unfavorable field condition most likely to be encountered if some reasonable planning can be followed in selection of terrain.)

The resistance due to grade can now be computed using $R_g = \frac{WG}{100}$ which is the simplified form of $R_g = W \sin \Theta$ and is sufficiently accurate for grades less than 20%.

For total load of tractor plus tractor plus missile

$$R_g = \frac{WG}{100} = \frac{149{,}000 \times 20}{100} = 29{,}800 \text{ lb.}$$

For towed load, which will give drawbar pull requirement due to grade,

$$R_g = \frac{WG}{100} = \frac{80{,}000 \times 20}{100} = 16{,}000 \text{ lb.}$$

To the above must be added the rolling resistance due to soil or road conditions. Assuming a tire pressure of approximately 25 psi

SUMMARY OF PRINCIPAL STATE HIGHWAY VEHICLE RESTRICTIONS

DESCRIPTION	CALIFORNIA	MAXIMUM	MINIMUM	PREVALENT
WIDTH	8' 4"	8' 6"	8' 0"	8' 0"
HEIGHT	13' 6"	N. R.	12' 6"	12' 6"
LENGTH				
Single Unit	35' 0"	N. R.	35' 0"	35' 0"
Tractor and Trailer	60' 0"	N. R.	45' 0"	50' 0"
MAXIMUM AXLE LOAD (LB.)				
Single	18,000	22,400	18,000	18,000
Tandem	32,000	40,680	26,080	32,000
MAXIMUM GROSS WEIGHT (LB.)				
3 Axle T. S. T.	76,800	86,400	45,000	73,200
4 or 5 Axle T. S. T.	76,800	86,400	56,000	73,200
Highest Weight Possible	76,880	88,000	55,980	73,200

some non-engineering problems . . .

Surface Description	Coefficicent X lb/lb vehicle wt.
Highway	.017
Road hard gravel	.025
Off highway medium	.040
Off highway soft or sand	.200

From the above, the total rolling resistance can be computed. $R_r = WX$. For the tractor plus trailer plus missile: $R_r = 149{,}000 \times .200 = 29{,}800$ lb. For the trailed load: $R_r = 80{,}000 \times .200 = 16{,}000$ lb.

The factor which is of interest at this time is the draw bar requirement placed upon the tractor due to the trailed load. It is a summation of the grade resistance R_g and the rolling resistance R_r.

$R = R_g$ plus $R_r = 16{,}000$ plus $16{,}000 = 32{,}000$ lbs.

It can be seen from the chart below that the Caterpillar DW-20 has a draw bar capability of 35,300 pounds. This is more than we require, but the figure is for *ideal* tractive conditions and it must be recalled that we used the ground condition of soft soil or sand. Let us now compute the draw bar capability using data from the following chart.

Tire Adhesion coefficient U

Surface description	U (static)	U (sliding)
Highway paved	.85	.70
Road hard gravel	.60	.60
Off highway medium	.60	.50
Off highway soft	.40	.20

For the Caterpillar DW-20, assume that 20,000 pounds of the tractor weight and 40,000 pounds of the trailed weight is on the rear driving wheels. Then the tractive ability on off-highway soft conditions is

$P = 60{,}000\ U_{st} = 60{,}000 \times .40 =$ 24,000 lbs. for static friction

$P = 60{,}000\ U_{sl} = 60{,}000 \times .20 =$ 12,000 lbs. for sliding friction

Since the tractive ability of 24,000 lb. for even the most advantageous static friction condition is less than the draw bar requirement of 32,000 lb. this tractor will not be able to pull the load up a 20% grade in soft dirt. In this case, power would have to be supplied to the trailer wheels if th terrain is to be traversed using th particular tractor.

The foregoing discussion presen merely a few of the problems in pr viding mobility for larger missile sy tems. These problems, however, ca be solved with equipment and desig that are well within the present sta of the art.

Aside from the engineering pro lems, there are several other problen listed below:

- Snow and ice conditions will b encountered at certain times of th year.
- Elevation above sea level wi proportionately reduce the engi horsepower output of naturally-aspirate engines. Turbocharged engines ha been evaluated, since their horsepow output is not appreciably reduced b the higher elevations.
- Minimum road widths, radii, an clearances at intersections must b studied. Maximum wheelbase wa found to be approximately 60′ 0″. T insure adequate equipment maneuve ability above this dimension, steerab trailer rear suspension was provide
- Maximum speed on the pave highway was established at 40 mp

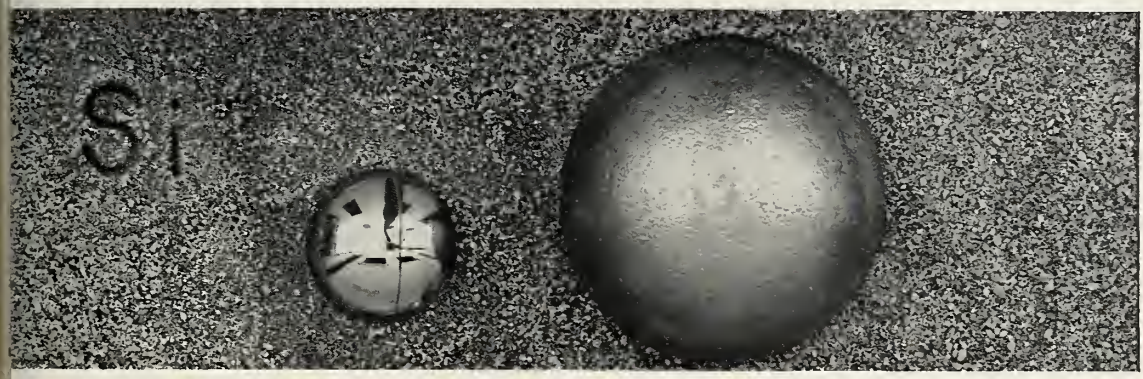
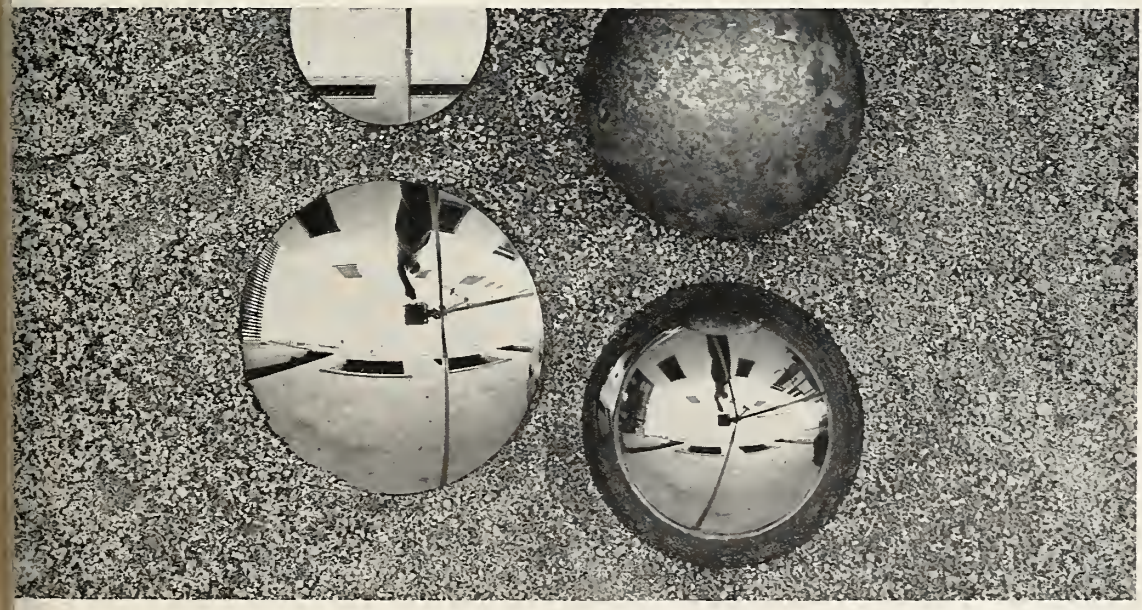
Now you can design silicon infrared optical systems with greater flexibility than ever before. Hughes has developed a new technique for *casting* pure polycrystalline silicon of the highest optical quality. Starting with cast silicon blanks — in shapes of flats ... domes (to 9" in diameter — and larger) ... lenses ... prisms ... Hughes can greatly reduce the necessary grinding. Result: economical silicon applicable to a wide variety of problems.

The high quality of these cast silicon parts has been established through extensive laboratory research. Spectrophotometric and scattering tests have proven that the optical properties of cast polycrystalline silicon are identical to those of single crystal silicon.



Wide variations in grain size proved to have no effect on scattering characteristics.



For additional information or more detailed test results please contact the Hughes sales office nearest you. They are located at:

The Search for Space Vehicle Power

Government and industry strive to find sources of electrical power that will allow man and his vehicles to undertake prolonged space missions

by Paul Means

WASHINGTON—Generation of electrical power during space flight is one of the vital obstacles to be overcome before man or his vehicles venture very far into space.

Manned space expeditions will either have to take along enough stored power, or generate enough power in flight to provide for communications, navigation attitude and flight control, fire control, and environmental control.

And electrical power needs will increase sharply in advanced space vehicles motivated by electric propulsion. According to studies by the Air Research and Development Command of the U.S. Air Force, power requirements for an electrically propelled manned deep space expedition could be as high as 30 megawatts.

Satellites are presently powered by chemical batteries, some rechargeable by solar cells. But the weight factor of chemical batteries and the inability of solar batteries to give large amounts of power instantaneously are drawbacks to their sole use in advanced vehicles and missions.

To meet the power needs of future space vehicles, industry, the services, and the National Aeronautics and Space Administration are experimenting with many different types of power supplies and converters. These include: advanced electric generators and chemical batteries, solar cells, thermionic converters, thermopile generators, thermoelectric generators, fuel cells, atomic power units (both isotopes and reactors) and magnetohydrodynamics.

• **Future needs**—How much electrical power will be required to run the equipment aboard space vehicles and missions planned for the next ten years?

According to an ARDC study, the secondary power needs of equipment aboard space vehicles now in the planning stage could vary from as little as two or three watts for certain reconnaissance equipment to upwards of 100 kilowatts for electric propulsion devices.

Specific secondary power requirements, according to ARDC, would amount to about one kilowatt for satellites in 300-mile orbits, hard impacts on the moon, and unmanned flights to the moon and back.

A soft landing or a manned flight to the moon and back would take about 1.6 kilowatts of secondary power, as would semi-hard or soft landings on Mars or Venus. About five kilowatts is needed to power the equipment aboard a stationary equatorial satellite, unmanned trips to Mars and Venus and return, and manned trips to the moon. Soft landings on Mars and Venus and back would require about 10 kilowatts.

Secondary power requirements increase many times if electric propulsion equipment is utilized to correct the trajectories of long duration space flights and to correct orbits of long duration earth satellites.

ARDC figures indicate that approximately 80 kilowatts of electrical pow will be required to obtain one pou of thrust from an ion propulsion devi with a specific impulse of 3000 se onds. If the specific impulse is increas to 20,000 seconds, the power requir jumps to 550 kilowatts per pound thrust.

Since a secondary power generati plant could not meet these demands, is suggested that a slight increase wou be made in the capacity of the genera ing equipment for the electric propu sion system in order that it may al serve as a source of secondary pow for the vehicle.

The ARDC study gave particul notice to the "specific power" requir to perform various missions. An ou put of 7 kilowatt hours per pound secondary power generating equipme is acceptable for most of the missio during the next few years, but lat missions will require from 50 to 2 kilowatt hours per pound of secondar power generating equipment. Syste weight in mechanical systems shou decrease during the same period fro 300 pounds per kilowatt to from 50 t 100 pounds per kilowatt.

• **20 KVA capacity**—The stud indicates that an advanced space v hicle of the 1965 era will need a ce tral power source with an entire sy tem capacity of at least 20 KVA.

In a study of the requirements c an electrical system for Air For weapons systems to be operational 10 to 15 years, a total environment w determined (see table). This enviro

Specific Secondary Power Requirements

MISSION DESCRIPTIONS	Secondary Power	
	Continuous Output	Specific Power (KWH/LB)
SATELLITES (ORBIT AT 300 MI) HARD IMPACT ON MOON AROUND MOON AND RETURN	1KW	7
SEMI-HARD OR SOFT LANDING ON MARS OR VENUS SOFT LANDING ON MOON AROUND MOON AND RETURN (MANNED) CONTROLLABLE ORBIT SATELLITE (APPROX. 22,000 MILES ALTITUDE)	1.6KW	50
ORBIT OVER ONE EQUATORIAL POINT (APPROX. 22,000 MILES ALTITUDE) SPACE STATION MANNED (APPROX. 22,000 MILES ALTITUDE)	5KW	100
SOFT LANDING ON MOON AND RETURN (MANNED) AROUND MARS OR VENUS AND RETURN (UNMANNED) SOFT LANDING ON MARS OR VENUS AND RETURN (UNMANNED & MANNED)	10KW	250

ent imposes the most severe condi-ons that all of the vehicles studied uld have to withstand.

Though some of the criteria would less extreme for certain space re-irements, the ARDC study recom-ends that all materials, components, d other hardware be tested in these al environment extremes and not be nsidered acceptable unless they with-nd all of the extremes.

In evaluating the different compo-nts that may generate the necessary wer for future space vehicles, the mary and most important criterion i weight. Depending on the type of ssion, the ability to produce large aounts of power instantaneously may an important criterion. Also, the tal amount of power needed in the hicle may decide which type of com-nent will be used.

As Dr. S. Fred Singer, Professor Physics at the University of Mary-ad pointed out in an article in M/R December, 1956, different power s>plies require different amounts of c>rhead, e.g. the initial weight invest-nt for a nuclear or fusion power s>ply is very large so that the supply b>ome economical only if the power r>uirements are fairly high.

Following is a survey of the vari-o> components that may be used as p>er sources in space vehicles, their o>imum applications, and their present s>te of the art.

• **Chemical batteries**—Non-charge-a e chemical batteries have applications f short space flights. They are always r dy for use, require no preparation, e lve no gas, pose no radiation haz-a , and have a reasonably long shelf li .

Mercury batteries are presently u d in satellites and will be for many y rs to come. One advantage is that th ir voltage does not drop off until n r the end of its useful life.

However, as the included chart pre-p ed by ARDC indicates, chemical b teries are not competitive with other t es of power systems if the flight is t last longer than ten days. For dura-ti s of over ten days, the specific w ght of the chemical systems in-c ases very rapidly but the specific w ght of the solar and nuclear sys-t s increase only slightly.

Rechargeable chemical batteries, i cluding fuel cell batteries, could be u d in conjunction with other power g eration devices, such as electric and th rmoelectric generators, solar, or n clear power.

• **Solar cells**—Solar cells are being c tinually improved and show many sp ce applications. In the photovoltaic c s (solar battery) presently in use, p oton energy from the sun disturbs th solid state equilibrium of the cell

Energy Output of a Power Supply Divided by its Weight

	Watt-hour/lb	Power Range (Watts)
Dry battery	14	<10
Activated battery types	25	<10
Re-chargeable nickel-cadmium battery	12	<10
Fuel cell battery	60	>100
Radioactive battery	10^4	<10
Nuclear reactor power supply	5×10^9 (max)	>100
Fusion power supply	5×10^{10} (max)	>100
Solar battery	infinite	<100

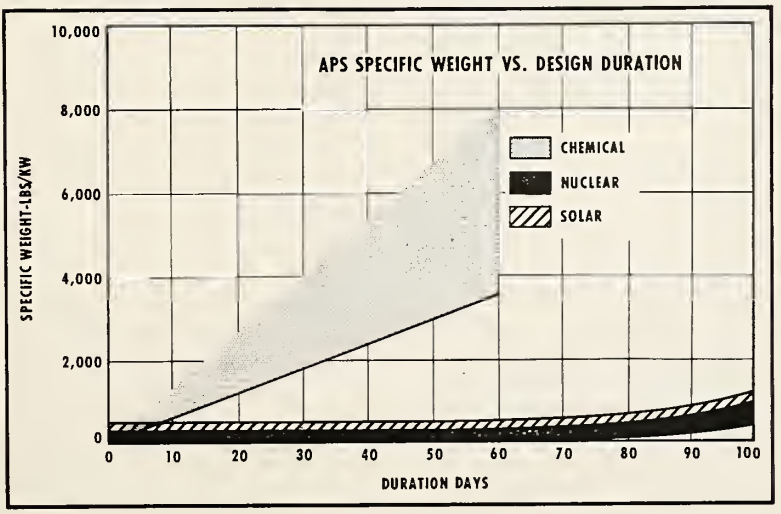
Prepared by Dr. S. Fred Singer

material, and an electric potential is generated which will cause a current to flow in an external circuit.

The solar energy input at the top of the atmosphere is 1400 watts per square meter (130 watts per square foot) and the measured efficiencies of present silicon junction photocells is about 10 percent. This gives an electrical power output of about 100 watts per square yard of battery.

Larger amounts of solar power can be produced if a number of cells are connected in series-parallel combinations. The two present disadvantages of such a system are present component weights, which would require 1000 pounds per kilowatt, and the old Christmas tree bulb problem. That is, if one of the cells is destroyed by meteoric impact, the total output of the series is destroyed.

Studies are also being made to determine the practicability of using concentrated solar energy as the heat source for a closed thermodynamic cycle. Using liquid or gas as the working fluid, the system uses a parabolic reflector to concentrate the sun's energy on the boiler of the system. The heated fluid from the boiler is expanded through a turbine which drives the alternator and the compressor or pump, and then waste heat is rejected in the radiator prior to sumping the fluid back to the boiler. Such a system would have an overall efficiency of 10%.



ARDC studies indicate that it would take about 80 square feet of concentrator projected area per kilowatt of generated electrical power. But the weight of the radiator make such a system impracticable until newer fluids and newer materials resulting in higher operating temperatures are found.

Before solar energy becomes a major power source for space vehicles, a heat storage unit must be devised which would not be subject to degeneration on re-cycling.

• **Electrical generators**—The Thompson Products Division of **Thompson Ramo Wooldridge Inc.,** has recently published a paper on the problems to be overcome in developing electrical generating equipment for space systems. Such generators, whether electrostatic, or electromagnetic, according to the Thompson report, will probably have to use direct radiation cooling, either directly from the motor frame to the ultimate heat sink of space at a temperature of about 40 F or from the motor frame to the vehicle skin which radiates to space.

According to the Thompson report, the alternator showing the greatest promise is the inductor-type having no rotating windings, no brushes, and capable of withstanding a high temperature environment without cooling, exposure to working fluids, and capable of high rotating speeds.

The type of generator used may depend on the type of propulsion system used. Ion types of propulsion, requiring high voltages and low currents, which is characteristic of the electrostatic generator. Plasma propulsion

QUANTITATIVE DEFINITION OF HYPER ENVIRONMENTS FOR ELECTRICAL SYSTEMS

Environments	Values
CONVENTIONAL	Existing Documents (MIL-E-5272, MIL-E-4970)
OZONE	11 parts/million at 13 mi to 21 mi
HIGH TEMP—AERODYNAMIC	0 to 47 mi 125°F to 932°F +
SHORT TERM RE-ENTRY ENVIRONMENT	60g deceleration and 932°F +
LONG TERM RE-ENTRY ENVIRONMENT	8g and 932°F
HIGH VACUUM	Approximately 0 pressure and 0 density
HIGH TEMPERATURE	5 Min to go from —68°F to 932°F, held at 932°F for 10 min, reduce to 752°F, hold for 1 hour, reduce to 702°F, hold 4 hours.
SOLAR RADIATION	1 to 100,000°A (Maximum Intensity at 4500-5000°A) as radiated by a "black body" of 6000 to 6500°K.
MECHANICAL VIBRATION	5 to 55 cps at 3/8 in. double amplitude
ACOUSTICAL VIBRATION	190 db, 30 to 10,000 cps
SHOCK	50 to 200g for 11±1 m.s.
ACCELERATION	8g for 1 min to 60g
ZERO GRAVITY	0g
EXPLOSIVE ATMOSPHERES	High Energy Fuels and Fluids
IONIZED GASES	Number of Electrons 1.5 x 10^4/cm^3 at 38 mi to 1.5 x 10^6/cm^3 at 159 mi
DISASSOCIATED GASES	Atomic oxygen particles 1 x 10^{12}/cm^3 at 56.5 mi to 5 x 10^{12}/cm^3 at 75.5 mi Range 50% to 100% atomic Atomic Nitrogen Particles 1.4 x 10^{12}/cm^3 at 56.5 mi to 1.2 x 10^8/cm^3 at 113.5 mi
AURORAE	565 to 285 mi 10^8 electrons/cm^2/sec at 100,000 ev 285 to 565 mi 10 to 100 kev X-rays with intensities of 1000-100,000 Photons/cm^2/sec
SOLID PARTICLES	.2 Microns to 8 cm Particles
MAGNETIC FIELD	2.5 Mev Protons above 250,000' to 500,000 feet (10^8 Protons/cm^2/sec)
EXPLOSIVE DECOMPRESSION	8,000' to vacuum instantaneously (10.2 psi) 932° to 1.9 x 10-12 psi
TEMPERATURE SHOCK	—65°F to 932° in approximately 2 min
PRESSURE SHOCK	S.L. to vacuum in 3 to 5 min
NUCLEAR RADIATION	Dose Rate Integrated
NEUTRON	2 x 10^{14} neutrons/cm^2/sec 7.5 x 10^{17}/neutrons/cm^2
GAMMA	4.5 x 10^9 roentgen/hour 2 x 10^{11} roentgen

Prepared by ARDC

systems, on the other hand, require low voltages and high currents, characteristic of electromagnetic generators.

The Thompson study points out that both types of generators have disadvantages to be overcome, and that the existing state of the art "falls far short of meeting the requirements of electrical generation in space systems."

The bulk of available equipment according to the Thompson study, has been built to specification MIL-G-6099, which requires only that units operate at barometric pressures ranging from 30" of mercury to 3½" of mercury, with the aid of 120C cooling air at sea level and 40C cooling air at 50,000.

Furthermore, present generators require too much cooling air, and are too bulky.

In order to meet these problems, the Air Force is sponsoring a program, sometimes called "Hotelec", to achieve a 600 F capability for the components normally associated with an electrical generation system.

Thompson has announced the development of an electrical insulation for motors, generators, and transformer solenoids suitable for 1000° F applications.

• **Thermoelectric generators**—The recent announcement by the Atomic Energy Commission that they had achieved practical power generation from the SNAP III thermoelectric generator demonstrated the feasibility of using thermoelectricity as a power source for satellites and space craft using nuclear energy and solar radiation. (See M/R, Page 29, June 22.) A thermoelectric converter or generator is essentially a number of thermocouples which are series parallel connected to obtain the voltage and current desired.

In a space vehicle, cold junction temperatures would be maintained by radiating heat from the cold junctions into space. The system is highly reliable because there are no moving parts. As in the case of the photovoltaic cell, this system requires series connection to obtain high voltages.

Because the converter is almost entirely an integral part of the reactor, it is unlikely that any part of the electrical circuitry would be damaged by meteorites. Although the specific weight of this system is presently rather high —about 1500 pounds per kilowatt— very large reductions are theoretically possible.

The **Westinghouse Corp.** recently completed a 100-watt unit for ARDC, called the TAP-100, which uses gas for fuel and is claimed to have an efficiency of about 8 percent. The thermoelecti material is a combination of sen conductors in cascade. An advanc version will use a nuclear isotope f source of heat.

• **Thermionic converter**—This cor ponent utilizes the same principle us in the familiar vacuum tube. He boils off electrons from the catho which then move to the anode setti up a potential difference between tl plate.

This potential is dependent on tl difference of the work function of tl materials utilized for the cathode ar anode. The greater the work functic of the cathode, and the smaller tl work function of the anode, the great the potential will be.

According to the ARDC study, e perimental devices have attained ove all efficiencies of over 8 percent, wi 30% theoretically possible.

Ultimately, the weight of this sy tem, according to ARDC, may be th least of all those considered. Both tl thermionic and thermoelectric co verters can be used with solar energ for the heat source, although the i creased probability of meteorite dan age reduces the attractiveness of th type of installation.

• **Fuel cells—The General Electri Company** recently announced the di

velopment of a practical fuel cell generating directly from hydrogen and oxygen in the air. Future progress could produce a chemical re-chargeable battery having great potential as a source of space vehicle power.

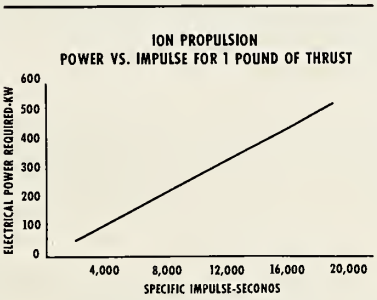
Basically the fuel cell converts the chemical energy of recombination of hydrogen and oxygen directly into electrical form. The output therefore consists of electrical energy and water. The water could then be circulated to a nuclear power source to be decomposed again into hydrogen and oxygen.

According to the ARDC study, storing of gaseous hydrogen at 6000 psi inside a tank of liquid oxygen at 500 psi (both at 150°K) could produce from the fuel cell as much as 100 to 120 watt hours per pound. A better approach, the ARDC study reports, could be the liquid storage of both hydrogen and oxygen with an output of 105 to 815 watt hours per pound depending upon duration of mission and year of mission (and current state of the art). The problem with this method is that hydrogen must be stored at –400° to 475° F and at that temperature its critical pressure is only 188.2 psi, too low for use in the high pressure cell without compression or super heating.

According to the ARDC study, the Redox (reduction-oxidation) cell offers great advantages over the hydrogen-oxygen cell in that it eliminates gaseous electrodes and can use cheap, crude fuels, such as kerosene, alcohol, etc. This cell promises from 266 to 860 watt hours per pound, and in cases where atmospheric "air" will always be available, it could produce up to 1200 watt hours per pound.

Limitations of fuel cells is their necessity to carry all the necessary fuel for the entire mission. One answer is to have a nuclear installation convert the water back into water and hydrogen in a closed cycle. ARDC estimates that a solar regeneration reactor could handle fuel for 10 watts per pound.

The thermal or nuclear regenerative fuel cell is in the early stages of R & D, and problems yet to be solved include the control of the rates and flow of both hydrogen and oxygen in the proper ratio to meet the required load, decomposition of the catalyzing electrodes in the electrolyte, fuel storage, and system weight reduction.



• **Magnetohydrodynamics** — Scientists are presently interested in the probability of generating an electric potential by passing a conduction fluid, a gas such as mercury at 2000° K through a magnetic field. According to the ARDC study, this principal seems to offer a specific power in the range of 100 to 1000 kilowatt pounds per hour. Work on this process is in the very early stages of research and development.

• **Atomic batteries**—Undergoing R&D at the present time, atomic batteries have only specialized applications for space flight in that they deliver only microwatts or possible milliwatts of power.

• **Nuclear reactors**—Probably the greatest supplier of both primary and secondary power for future space vehicles will be nuclear power from both isotopes and reactors.

In applications requiring more than 100 to 1000 watts, nuclear power is practically without competition. It also can be used to generate electrical power through the use of either static or mechanical power conversion devices as was the case with solar power.

Essentially the nuclear reactor acts as a heat source, approximately one billion B.T.U.'s are produced for every ounce of uranium which is fissioned. The engine itself can be run hot, limited only by the strength of materials at high temperatures.

The two major problems with a nuclear power source is heat dispersal and radiation. In his article, Dr. Singer proposed that nearly all of the heat could be radiated away into space, keeping the exhaust temperature in the vicinity of the freezing point of water if the satellite is built large enough with a large radiating surface. Dr. Singer states that the area in square yards is given approximately by expressing the energy to be radiated in kilowatts.

The shielding problem reduces the attractiveness of the nuclear system for manned flights with low secondary power requirements. But shielding increases only slightly with increased output and at high power levels is only a small fraction of the total weight.

One solution to the radiation problem for space flights not requiring large accelerations has been proposed by Dr. Singer. His idea is that the reactor power supply on take-off could be integral with the space vehicle but would be shut off, all of the power being furnished by batteries.

On reaching orbit or whenever the propulsion system is off and the acceleration becomes zero, the reactor would be removed to a safe distance from the space vehicle, with only a cable connecting the two. Then the reactor can be turned on by remote control and electricity piped into the space vehicle. Similarly, for landing, the reactor would be shut off first before it is brought close to the vehicle.

Steel Melting Processs Avoids Contamination

PITTSBURGH—Firth Sterling Inc. has developed an arc melting process for purifying steel that avoids contamination with refractory compounds.

The process, invented by Firth Sterling's R. K. Hopkins, involves melting an electrode under a controlled slag at a controlled rate in a water-cooled mold.

The molten slag protects the metal from the atmosphere. In addition, Firth Sterling reports, the composition of the slag is such that it neither adds undesirable elements to the metal nor removes desirable elements. Furthermore, the slag provides an ideal ionized path for the support and stabilization of the arc.

When melting titanium-bearing minerals, or any materials having elements that react with the oxygen or nitrogen of the air, the slag blanket is very effective in removing the resulting refractory compounds. Air melted material, which ordinarily is used for electrode stock in consumable electrode processes, invariably carries non-metallic inclusions, the company noted.

The inclusions are broken up and dispersed but are not eliminated in vacuum arc melting. In the Hopkins process, Firth Sterling said, the inclusions float to the surface of the molten metal and then are absorbed by the slag blanket.

An improvement in macro and microstructure is realized, the company declared, particularly in large ingots. Firth Sterling says it is making further improvements in melting to produce fine grained ingots, and the fine grain, with proper forging and rolling technique, can be maintained through to the finished product.

The company said the steels and alloys produced by the Hopkins process are A-286, 16-25-6, Discaloy, Waspaloy, Inco 901, PWA 1002, SAE 9310, SAE 4340, SAE 3312, tool steel and high-speed steel.

NEWS IS HAPPENIN

RADIOPLANE CREATES FIRST FAMILY OF UNMANNED AIRCRAFT TO T

Radioplane is the world's leading producer of drones and space age recovery systems. As live targets, drones perform as aircraft—then can be recovered by parachute. As evaluators, drones simulate the appearance of the enemy threat while they score our weapon systems' effectiveness. On surveillance missions, drones are zero-length launched, fly cameras, take photos, and return with information within minutes.

Typical of the high-performing Radioplane targets is the RP-76. This smallest target yet fired upon by missilemen is rocket powered, and it has the radar appearance of a large aircraft.

Hope Sustains Monopropellant Work

Despite their many disadvantages, the odd fuels continue to attract government and private researchers who hope for a 'near-miracle' to boost their I_{sp}

by S. David Pursglove

WASHINGTON—How do monopropellants figure in the nation's missile plans? Where will these handy, one-squirt propellants be used in our defense and space sciences programs?

The answer, in a nutshell, appears to be, "they won't."

They won't figure in our plans, they won't be used in our rockets. That sums up Washington's best-informed opinion on the current state of monopropellants. That's the answer, stripped of platitudes, euphemisms, and apologies from officials of the three services, the National Aeronautics and Space Administration, a handful of propellant firms, and government-contract study organizations.

Why, then, are almost all of these people engaged, to some degree, in monopropellant research?

• **A someday thing**—The answer to that question is the same answer that could be used in reply to the question, "Why research at all?" for hundreds of years, past and future—hope.

One official sums up the typical government feeling: "Even though the specific impulse of all practical monopropellants is very low, and probably will remain low, the government recognizes their advantages and hopes that some near-miracle will bring about a marked increase in specific impulse."

He cautions that none of his people who are authorities on propellants knows of any breakthrough in the offing. "For this reason," he says, "government interest is flagging considerably, but there always will be a small spark of interest."

"Small spark" is just about all the government interest amounts to right now. We queried a top Air Force official about monos, and he had this to say: "Sure, I can talk to you about them—there's nothing worth keeping secret. Seriously, though, I can't discuss the amounts of money we're spending on research contracts because that would reveal the level of our effort."

By the time we had talked with him and several others, it was apparent that the Air Force level of effort is extremely low. (The Navy's is a little higher.) But, on every hand—here too—we ran into this "We'll maintain a spark of interest" attitude.

Why any interest in monopropellants at all? Why should the fact that official U.S. interest in monopropellants is lagging even be worth a news story?

The answer lies in accepted descriptions of "monopropellants." There are no widely accepted, simple, compact definitions of monopropellants—it is more what they *aren't* than what they *are*. For example, one author distinguishes between the two major classes this way: A bipropellant is a system of a fuel and an oxidizer, whereas when the fuel and oxidizer are wrapped up in a single molecule, the propellant is a monopropellant. This is true—but does not cover all cases. However, a monopropellant does involve just one homogeneous solid mixture or compound, or just one homogenous liquid, although the homogeneity may be the result of thorough mixing of several ingredients.

Examples of true monopropellants include the solid nitrocellulose (a single molecule capable of sustaining its own combustion), and the liquids nitromethane (a single molecule) and nitropropane-nitric acid (a homogeneous mixture of a fuel in an oxidizer.)

• **Advantages**—Now, what is so great about this? In the case of solid propellants, not much. But, in the case of liquids, the monopropellant requires only one storage tank, one pumping system, one filling hose, one filling operation, one tank within the missile, one pump within the missile, one route to the combustion chamber. On the other hand, a propellant system of a fuel and an oxidizer—kerosene-LOX, etc.—requires *two* of everything.

The monopropellant saves considerable weight within a rocket. Equally important, it saves storage space and cuts down handling problems at launching sites. This is important when it comes to shipboard missiles, and explains why the Navy is devoting more attention to monopropellants than does the Air Force which can operate from fixed, land-based sites.

It may also provide a clue to the Army's thinking about mobility, or to the Army's missile plans. Monopropellants, logically enough, would be of great value to a mobile army. However, the Army went on the record with M/R this way: "The Army has a very small interest in monopropellants—the interest is mainly in the Air Force and Navy."

Nonetheless, all missile-oriented agencies have a continuing interest in monopropellants for another use. These handy propellants are used to operate auxiliary power systems; most often they decompose to provide expanding gases which operate turbine pumps or generators. The monopropellant allows engineers to hold APU size and weight to a minimum.

How Do Monopropellants Compare?

Specific impulse of monopropellants under study versus I_{sp} some typical bipropellants

Propellant	Appx. I_{sp} (sec)
Monopropellants	
nitromethane	190-230
ethylene oxide	160-190
hydrazine	160-190
hydrogen peroxide	160-190
Bipropellants	
aniline-nitric acid	220
JP-4-nitric acid	200-230
hydrazine-nitric acid	230-260
gasoline-LOX	240
RP-1-LOX	300
hydrazine-LOX	315
hydrogen-ozone	400
hydrogen-fluorine	410

• **And disadvantages**—If monopropellants have so many advantages, why aren't they widely used—why so little interest?

This is the easiest question to answer in the entire missile business: the disadvantages outweigh the advantages. Those disadvantages fall into two major categories:

(1) The monopropellants just aren't powerful enough.

(2) They are too hard to handle; detonate too easily.

None of the near-practical monopropellants can hold a candle to most of our widely used bipropellants (see box).

The handling problems are explained by a paradox in the requirements for a monopropellant: It must be stable enough to store, yet be highly combustible without an added oxidizer. So far, most monopropellants have sacrificed handling safety for combustibility.

• **Three classes**—In general, there are three types of monopropellants, classified according to the way they function:

• Single molecules containing both the fuel and oxidizer. Popularly, this is visualized as a molecule "with the fuel at one end and the oxidizer at the other."

• Compounds (as opposed to mixtures) which undergo exothermic decomposition as a result of molecular structure. These single substances decompose to release heat because the arrangement of atoms is not stable

• Mixtures of fuels and oxidizers.

Monopropellants and Industry

These firms have monopropellant interests

*Aerojet General • Air Products Corp. • Allied Chemical • American Rocket Co. • *Atlantic Research Corp. • Becco Chemical Div., FM&C • Dynamic Devices, Inc. • Fulton-Irgon Corp. • *Hughes Tool • Olin-Mathieson Chemical • *Pennsalt Chemical • *Phillips Petroleum • *Rohm and Haas Chemical • *Rocketdyne • Shell Chemical • Special Products Lab., FM&C • *Stauffer Chemical • *Thiokol Chemical • Topper Manufacturing*

*Known to be doing considerable work in monopropellants

Here the paradox of requirements discussed above really comes into its own. Naturally the fuel-oxidizer must be a combustible mixture, but on the other hand, it must be possible to mix, store and handle it without danger of combustion.

• **Some examples**—One of the most famous monopropellants of the first class above is nitroglycerine. It is too unstable for use as a liquid monopropellant, since the reaction from the liquid state is detonation rather than combustion. However, just as clay or sawdust slow down nitroglycerine in dynamite, so do certain plastics and rubbers slow it down to make it an effective ingredient of some solid propellants.

Hydrogen peroxide, usually thought of as an oxidizer in a bipropellant system, is a monopropellant when its decomposition is catalyzed. The catalysts usually are permanganates, often calcium permanganate as used by Germany in World War II.

A more recent monopropellant under serious consideration is ethylene oxide. This is an important industrial chemical, the starting point or major intermediate in many commercial processes. Therefore, when new ethylene oxide plants, or expansions of existing plants, are announced, there is no reason to believe they are to supply the missile industry.

This, by the way, is true also of nearly every chemical propellant. Some of the major industrial chemicals that mislead followers of the missile industry into believing the quantity and variety of propellants are expanding, are nitric acid, liquid oxygen, hydrogen peroxide, and ammonia.

Ethylene oxide is produced in the laboratory and in some plants by reaction of ethylene chlorhydrin with an alkali. Most plants, however, produce it by direct oxidation of ethylene. This process route will keep the petroleum industry interested in missiles even after kerosene and other petroleum fuels are no longer used. Ethylene oxide has one drawback. Its low boiling point of 51°F means that it must be refrigerated for use as a liquid.

The most widely discussed monopropellant is nitromethane. It detonates very easily, and is quite hard to handle. A saving grace is that the nitromethane molecule exhibits a semi-polar double bond. The double character contributes the kind of instability necessary in a monopropellant; the semipolarity aspect makes it miscible with other polar compounds, including water and alcohols.

Diethyleneglycol dinitrate (DEGN), like nitromethane, is a nitrated hydrocarbon. However, the DEGN molecule is more complex. It is made by the direct nitration (with nitric acid) of diethyleneglycol vapors. Like nitroglycerin, to which it is close kin, DEGN is a very unstable liquid, but can be controlled as an ingredient of solid propellants.

• **Government approaches**—Here is a summary of what the various government agencies are doing in monopropellants, or say about them:

The AIR FORCE is still interested in monos because of their obvious advantages, but interest is at a low ebb because of the higher specific impulse of other, easier-to-handle propellants. AF is looking at hydrogen peroxide, propyl nitrate, and ethylene oxide. Nitromethane is about out of the pic-

Project MAST Being Stockpiled

ATRAN guidance systems produced for the Air Force's *Mace* system are being warehoused by Goodyear Aircraft along with support equipment. Unique world-wide military electronic supply program is dubbed "MAST," for Missile-Automatic-Supply-Technique. It brings "push-button" notice when parts are needed anywhere on globe.

rundown of company effort . . .

ture because of handling difficulties.

Fiscal Year 1959 contractors are **Pennsalt Chemical, Hughes Tool,** and **Phillips Petroleum.** On June 1, the AF announced invitations to bid on research in high-energy monopropellants, including solids and storable liquids. Conventional storables will occupy Air Force interest for the next five years. By then there might be a breakthrough in monos. Biggest monopropellant interest right now is amines.

The ARMY has little interest in monopropellants, and is willing to let the Air Force and Navy blaze the trail. However, **Rohm and Haas Chemical** is doing monopropellant work for the Army at Redstone Arsenal.

NASA has little interest because much of its work on chemical fuels is actually done by the services. However, NASA personnel formerly with other agencies have carried with them a strong interest in monos, and the space agency is conducting some work in the field.

The NAVY's Bureau of Aeronautics has a keen interest in monopropellants. Naval Ordnance Laboratory is doing some work, and Naval Research Laboratory "has a couple of old projects kicking around." The Navy sponsored a monopropellant symposium in New York May 5-6. An official of a government contract study organization says the Navy is by far the most interested Federal agency.

The Navy talks a lot about having made a breakthrough—a monoprop that has a high specific impulse and is safe to handle—but, since no details are available and since Navy scientists can only allude to "our secret discovery," many chemists ignore the talk.

Commerce Department's OFFICE OF TECHNICAL SERVICES prepares continuing bibliographies of work in government laboratories or in private labs under government contract. Although there have been many reports on propellants in recent years, there have been none exclusively on monoprops.

• **Industry effort**—Here is a rundown of what some of the companies are doing:

Thiokol Chemical is doing a lot of research, but is not running any engines on monopropellants. The firm is looking at high-energy, stabilized monopropellants that are safer and more powerful than nithromethane. One engineer describes them as having "bastardized molecules." By this, he says, Thiokol is synthesizing hopefully ideal monos. Chemists at Denville (N.J.) start by describing the desirable characteristics of a monopropellant, then try to build the molecule.

A Thiokol spokesman says the known compounds are no longer useful—they have been surpassed by missile needs. The chemist then has two choices: Look for other compounds; synthesize.

Rocketdyne "is very definitely in monopropellants," says a spokesman, but the company is not able to describe its work in detail.

Astrodyne has no interest in monopropellants as they are usually thought of—as liquids—since the company is limited to solids. However, Astrodyne is interested in the solid equivalent of monos: homogeneous solids.

Phillips Petroleum is very active in monopropellant research for the Air Force. The firm's special interest is in high-energy monoprops.

Aerojet-General is doing "practically nothing" in monopropellants right now, a spokesman says, but does support a continuing program on the chemistry of nitro-compounds for possible monopropellant use. In the past, Aerojet has looked at nitromethane, but decided its detonability and generally dangerous handling properties could not be overcome. The company still is interested in ethylene oxide and propylnitrate for a gas generator.

If Aerojet chemists develop an acceptable monopropellant, it might be either a liquid or a solid, but probably will be a straight organic compound—nothing fancy.

Atlantic Research recently developed a heterogeneous liquid monopropellant, Arcogel. **Thompson Products** holds exclusive licenses on both the gel propellant and burner system. Thompson plans gas generating and propulsion applications.

Stauffer Chemical is one of the firms most interested in monopropellants. Stauffer was host at the New York symposium sponsored by Navy BuAir.

Wyandotte Chemical is working with ethylene oxide and other monopropellants. The company's other monoprop intcrests cannot be identified, but some work is being done for BuAir. Industry sources believe this is under a contract that calls for development of a monopropellant with an I_{sp} exceeding 250 seconds.

Air Reduction Company has done some almost basic research that was applied to monopropellants. Combustion and Fuels Technology enginee G. A. Mead wrote on "Compressio Sensitivity of Monopropellants" in th American Rocket Society Journal June, 1959. However, his work wa done in 1958.

Among other recent papers o interest is "Improvements in th Operating Characteristics of n-Propy Nitrate," W. H. Lawrence and W. P Knight, Aerojet-General, in AR Journal, January, 1959. They sum marize Aerojet-General's work on a gas generator designed to use propy nitrate.

The Navy's "breakthrough" mono propellant is described by J. D. Clark Naval Air Rocket Test Station, in Astronautics, September, 1958 (p. 34)

Aerojet Courts Goodwill of Its Workers' Wives

SACRAMENTO—Planned tours of the rocket plants here are being conducted by **Aerojet-General Corporation** in an effort to reduce dissatisfaction among wives of employes who work long hours. The evening tours attracted over 500 wives during the first month of the schedule.

The highlight of each tour is the firing of a liquid rocket engine in the test area, which the wives watch from the observation post. The company reports that the tours have resulted in increased apprcciation by wives of the need for long hours put in by company personnel.

Storable Oxidizer Has High Oxygen Content

NEW YORK—Hummel Chemical Co. reports that its propellant oxidizer Tentranitromethane, $C(NO_2)_4$ is a stable, storable liquid with an active oxygen content only a little less than liquid oxygen.

In a new technical data sheet, Hummel says TNM has 1.07 G/CC of active oxygen, compared with 1.14 for LOX. However, TNM has a density of 1.64 G/CC, almost 50% higher than LOX's 1.14.

TNM can be stored for long periods below 40° C in mild steel drums or tanks, Hummel says. The oxidizer is stable up to 100° C. It melts at 12.5–13.7° C and boils at 125.7° C. Hummel reports pure TNM is relatively insentitive to impact or adiabatic compression, but the sensitivity is greatly increascd in mixtures with hydrocarbons or entrapped air. TNM is available in commercial quantities.

The Role of Solids Is Growing

Survey shows they are involved in virtually all weapon systems and the problems connected with their use—including I_{sp}—are finding solutions

by Frank G. McGuire

LOS ANGELES—"Given the same development time and research funds that liquid propellants have had, solid propellants should someday be able to do almost any job the liquids can do," says Dr. Cledo Brunetti, Vice President and General Manager of **Grand Central Rocket Company.**

"For immediate and any conceivable future military applications, solids will play a very significant part, and we further intend to strengthen their role in this area. As far as space applications, I think there will be a substantial amount of solid rocket motors used," says Dr. E. R. Roberts, Manager of **Aerojet-General's Solid Rocket Research and Development Division.**

These are the general reactions of two companies with heavy business investments in solid propellant rocketry. Despite the 100-seconds-higher specific impulse that solids still must concede to liquids, there are no plans afoot to "scuttle" the solid-propellant business. On the contrary, Grand Central has invested $3 million since September in new facilities to carry out the aim of its vice-president and general manager.

There are solutions now in existence, or in sight, for many of the problems that have plagued solid propellants in the past. Nozzle-cooling is virtually solved, combustion instability has been eliminated, reliability is over 99%, grain size is practically unlimited, and temperature ranges have been greatly expanded, these authorities say.

• **A place for both**—It is conceded that solids still must make considerable progress before displacing liquids in those applications where high specific impulse is the prime requirement for the mission. The general picture is, however, that for military purposes, nearly all new systems now under development call for solids *(Minuteman, Polaris, Pershing,* et. al.). It is therefore very difficult to say "it is all liquids" or "it is all solids" when looking at the future of propulsion for the next decade or so.

Grand Central and Aerojet officials were interviewed in connection with this survey because their work is typical. As the story indicates, other companies are involved.

Until recently, there was still a fairly clear-cut division where the large units needing high I_{sp} were liquids, and the small tactical rockets, which needed instant readiness characteristics, were solids. We have now reached the point where it is possible to produce huge solid-propellant rocket motors and still retain the advantages of reliability and instant readiness. By steadily increasing specific impulse levels, the solid-propellant people hope to eliminate all the disadvantages of solids, relative to the liquid systems.

• **Shifting border**—There is considerable optimism that this will be done, and it appears that the borderline between the two systems is shifting back and forth with the intermingling and overlapping of the respective systems and their missions. So it is now necessary, not only to determine whether solids or liquids should be chosen, but also exactly what propellants can be tailored to the job.

There are few large firms in the field of solid propellants that do not also have an investment in liquids to some extent. Aerojet-General is definitely in all type of propulsion. Grand Central's parent companies, **Tennessee Gas** and **Food Machinery & Chemical,** are both in the liquid-propellant field, and Thiokol has its liquid-oriented **Reaction Motors Division. Astrodyne,** jointly owned by **North American** and **Phillips Petroleum,** has strong ties through both Phillips and NAA's **Rocketdyne Division.**

It can be seen that none of these firms can afford to ignore the advantages of liquids, and must therefore "keep both feet on the ground," when evaluating various systems. All are in business to stay. As Grand Central's Dr. Brunetti puts it: "We expect to be in the solid propellant business for a long, long time and we are tied to the economics of it."

• **Performance**—The highest level of specific impulse reached to date is above 250 seconds, well over what was thought to be the solid-propellant "bar-

MIXING blades in Grand Central's 350-gallon mixer, ground to extremely close tolerances and constantly X-rayed for signs of weakness.

rier" of 240 seconds. New propellants and techniques are incrementally raising this level. The goal set by ARPA for the immediate future is 280 seconds, and this is expected to be reached in substantially less than five years. Specific impulse of 300 seconds is hoped for in a few additional years, and this would involve as yet unexplored techniques of separating the extremely energetic ingredients, one from the other, in solid-propellant systems.

Specific impulse importance varies with the stage under discussion. On the *Minuteman*, for example, the exchange ratio of range to specific impulse is more important on the first stage than on succeeding stages, merely because of the greater amount of propellant involved. It is therefore desirable to have higher I_{sp} in the first stages because of the more favorable exchange ratio. On the other hand, the exchange ratio for burnout weight (the penalty in reduced-range paid if the burnout weight of any given stage is increased) makes it important to reduce burnout weight in succeeding stages. Mass fraction is expected to increase from the present level (around .93) to .96 in a short time.

The increases in performance expected of solid-propellant rockets generally varies with the timetable given. There is a lag time estimated at from two to four years between laboratory achievement and production-motor achievement of specific impulse levels. However, according to Aerojet's Dr. Roberts: "It is evident that we are going into larger and larger sizes, but it might not be so evident that the physical properties will be a more significant parameter than the specific impulse, the burning rate, or any other parameter, which in the past used to be the primary concern."

• **Propellants**—Raising the I_{sp} levels will undoubtedly depend primarily on propellants and their processing. In this respect, the greatest advances in propellants in the past year have been in physical properties, temperature ranges, etc., and the best propellant for maintaining ability to withstand thermal stresses in case-bonded motors appears to be nitropolyurethane. With certain additives, it appears to have an all-around bright future.

Aerojet's work with the nitropolyurethanes stems from research sponsored by the Office of Naval Research. The polyurethane propellants being studies at AGC result from basic work done by the **Jet Propulsion Laboratories** in Pasadena. Most of Grand Central's work in composite propellants has been on ammonium perchlorates with rubber binders. (A composite propellant is one which has a crystalline oxidizer with a rubbery fuel binder. Instead of the two high-energy components, nitroglycerine and nitrocellulose, which characterize the double-base propellants, it has discrete particles of oxidizer embodied in a rubbery binder.)

Further work at GCR is aimed at four fundamentally different types of rubber binders of a high-energy nature. It is from this work that GCR expects to get ten to fifteen seconds more I_{sp} than from regular rubber binders. (Also, through some "rather interesting" approaches to design, GCR hopes to drastically improve mass ratio.)

Both Aerojet and Grand Central Rocket Co. have been working on new processing methods for solid propellants. One more advanced than most is the continuous mixing process, which allows propellant-mixing right at a launching site, if necessary. The capacity of the system depends on the type of propellant being mixed. Aerojet says it has demonstrated a pilot-plant operation of the continuous mix process. Grand Central has also been at work on the technique for some time, and pioneered the method.

In addition to the continuous mixing process, the development that has pointed the way to the huge solid-propellant motors is the technique of producing fuel systems which can be made to solidify without evolving heat.

Development of various techniques has allowed production of large propellant grains that do not create sufficient heat to warm the grain. Hence it is possible now to create grains of almost unlimited size, and cure (or solidify) them without fear of a combustion disaster.

In addition to work with nitropolyurethanes, polyurethanes, modified nitropolymers, and hydrides, AGC is looking forward to adaptation of the high-energy components of liquids into solids, a field in which Grand Central is also strongly interested. As things now stand, it is not possible to calculate a system using solid propellants which would give the same order of specific impulses as a liquid system, regardless of the solid propellant used in the calculations.

• **Combustion stability**—Once a plague on the solid-propellant field, combustion instability is said to be non-existent in modern propellants. One of the best cures for the problem was addition of metals to the propellant to raise the specific impulse level. The metals, the most common of which aluminum, also solved the combustion instability problem through happy coincidence. Quality control has also helped. According to Grand Central, once a motor and propellant are designed, tested and kept under tight quality control, the problem of unstable burning, once eliminated from early test models, is permanently absent.

• **Temperature range**—"More than half our problems are associated with the requirement that we operate within –65° to 165°F, and this requirement is expanding," says a harassed solid-propellant engineer. "We are being asked to meet temperatures of 250°F, and for very special applications, up to 400°F."

In the low I_{sp} areas, from 200 to 230 sec., great temperature ranges have been met. Examples are the *Sidewinder, Zuni, Asroc, 2.75* rocket etc. In the *2.75*, the propellant operates the same from –30°F to 130°F and through chemistry doing the job performance-wise in the missile, over 150 pounds of fire-control and other electronic equipment has been eliminated from aircraft.

• **Nozzle cooling**—The evolution in nozzle cooling has reached the point where Grand Central Rocket considers it "quite obsolete" to route fuel or oxidizer through the nozzle walls for cooling, when there is a lightweight plastic nozzle available for liquids as well as solids. (With the exception of the extremely large liquid engine.) Among the methods used in conjunction with the plastic nozzle are film cooling, ablation, transpiration and auxiliary propellant charges.

Film cooling, in which a film of material is introduced between the flame and the nozzle, utilizes a material which is solid in storage, but which liquifies under high temperature and flows across the surface to be cooled. The nozzle developed by **Douglas** for use with the GCR *Nike Zeus* motor is an end-grain refrasil, essentially a fibreglass material with a high-grade resin.

A combination system using the self-cooling nozzle with some auxiliary film cooling does not appreciably downgrade the I_{sp}, and represents one of the methods which prevent heat from getting to the nozzle in the first place. The problem is not one of cooling (a heat-sink nozzle would do that), but one of cooling lightly and efficiently.

• **Reliability**—"To state it fundamentally, when you are using a solid propellant motor, you are using the product of a chemical plant which is still back at the factory. When you are using a liquid rocket, you are dumping raw materials into the missile, which then must act as a chemical plant."

metering, mixing and controlling the fuel and oxidizer. There are a lot more things that can go wrong when your chemical plant is airborne, then when it is sitting on the ground and you control the product." This is the case for reliability as the solid-propellant-rocket manufacturer sees it.

If a solid-propellant system is properly designed, thoroughly tested and tightly controlled for quality, there is no resaon why 99% reliability cannot be attained, they say, and point to the outstanding records already established. The *Viper* rocket, produced for sled use by GCR, has demonstrated reliability in excess of 99% in a long series of runs. (In discussing reliability, sources made it clear that they were not including JATO units, and other low-performance solid-propellant motors in the reliability factor.)

The Air Force clustered 21 of the *Viper* motors on a sled four times and 39 motors once during the first week of June, to drive test sleds at high Mach numbers. About 700 of the *Viper* motors have been fired. They are not the "workhorse" type rocket, but are a recently developed, high-performance motor having a performance index of over 160 . . . considered very high.

In the clusters fired at Edwards, Holloman and other bases, reliability is vital, because of the expense of sleds, their special design, etc. Of 162 rockets ordered by Edwards AFB since last February, not one has failed to fire. They get GI handling, and are production rockets, not specially "mothered" laboratory models.

• **Casings**—Thin-walled motor casings, another shining goal of solid-propellant men, has reached the state where Grand Central Rocket is working with casings having thicknesses of less than 100 mils, and Aerojet's Aerowrap process, involving spiral wrapping of the steel casing, has produced .015″ walls.

Although Aerojet says it is not now employing the Aerowrap process, the company is believed to have produced a considerable number of casings by the method with wall thicknesses of less than .050″. Design strength of the casings was said to be 250,000 psi yield strength, but actually is 265,000 psi, and "ultimate failure has been occurring between 300,000 and 330,000 psi." Once the desired thickness is determined, the spiral wrapping of steel is begun and the necessary amount of layers added until the thickness is as specified.

• **Hybrids**—In the midst of the solid/liquid melee stands the poor relative of both: the hybrid rocket. Grand Central Rocket Co., noting that the most vulnerable parameter of solid-propellant rockets is thrust-level control, is strongly considering the hybrids. The firm "has some ideas" about the system and may come up with a unit having liquid oxidizer and solid fuel (which would also serve to pressurize the liquid propellant tank). The system is expected to provide a three-to-one thrust-control capability which would be adequate for many applications.

No hybrid systems are being considered by Aerojet, which feels that a hybrid system "buys the disadvantages of both liquids and solids." No other techniques for thrust-level control are being pursued at AGC except complete termination of combustion.

• **Costs**—One of the hottest topics tossed about during M/R's interviews was the subject of costs. The major points of difference that solid-propellant men have with their liquid-propellant counterparts are: "It is not necessarily what system will put the biggest payload on the moon?", but the question is "What will it cost?" The other point is "It's not the propellant cost we have to worry about, it's system cost—or mission cost."

J. J. Crowley, Vice President—Project Management and Marketing for Grand Central Rocket Co., feels there is reasonable doubt that the amount of cost per pound for payload on the moon is clearly an advantage of the liquids. His company feels that the best way to determine which system to employ in any space application is to conduct an operations research study, to show the total cost of delivering whatever payloads are called for. This would cover every cost connected with the program, including development and ground support facilities.

Similarly, D. F. Sprenger, Associate Manager of Aerojet's Solid Rocket Research & Development Division (and head man on their *Minuteman* work), feels that a good example of low-cost space research with solids is the *Scout* program, the first major application of solids to this type of work. "Possibly a year from now, we will be able to more accurately assess just where solids fit in, but it looks to us right now as if it is a very low-cost method."

The actual development cost of a million-pound-thrust solid-propellant motor is "considerably lower" than the cost of a million-pound liquid engine, and Grand Central Rocket would "gladly" take a contract to build a 20-million-pound-thrust solid rocket, because of the relative ease with which it could be done, compared to a liquid engine with the same order of thrust.

"And in the future, it will be the development cost that really matters," says Dr. Brunetti, "because many of these things we are working on will never, in the true sense of the word, be 'produced.' We may make 200 development units of a very large rocket, then actually produce only 300 'production' units."

• **Problems remaining**—In the final analysis, there are several areas in which solids are making strong efforts to whittle down large advantages enjoyed by liquids. The areas of specific impulse, thrust-level control, acceleration control and similar characteristics, are among the most vital.

Asked what was the next hurdle they would like to see cleared in solid propellant technology, Aerojet spokesmen cited the need to find a method for coating hydrides, or the protection of high-energy materials so that they can be incorporated into solid propellants without prematurely reacting. This accomplishment would move the technology to the next major "plateau" of specific impulse. Grand Central's answer, while granting the need for a method of coating hydrides, was to raise specific impulse without compromising the temperature range of a missile, and actually to expand it.

Beyond these problems lie others, but the future looks promising. In the words of one company official: "What solid propellant rocketry would like to have is a solid form of high-density hydrogen."

TEST FIRING by Aerojet of large solid-propellant rocket engine for guided missile launchings. The company is working on the solid propellants for the Navy's *Polaris*.

Cooling Gear Gets New Emphasis

Experts say heating problems in missiles and support equipment will grow and design must be done early—first of a two-part survey

by Hal Gettings and Charles D. LaFond

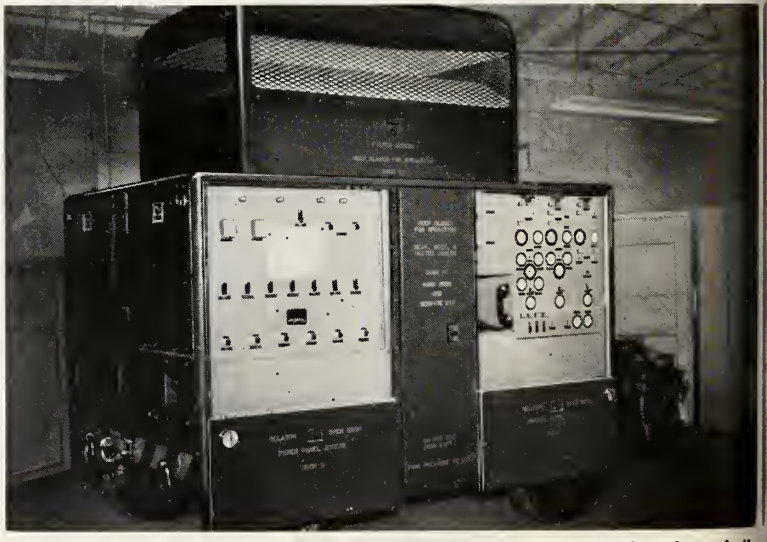
WASHINGTON—Vital to the achievement of optimum performance is electronics cooling, a major link in assuring high reliability in missile electronic systems and components. A multimillion-dollar business, it is all too often a stepchild in early equipment and system design. An M/R staff survey into this very important area of missile and ground-support equipment design brought two similar responses from each of the companies queried:

1) As a result of increased component density in micro-miniaturized circuit design, increased power requirements per unit volume, and aerodynamic (environmental) heating will continue increasingly to cause system degradation in missile and ground-support electronic systems.

2) To combat this, systems should include at an early stage of design and throughout development the services of competent cooling-system design engineers.

We have long since passed the time when free convection would satisfy the requirements for cooling electronic equipment in the majority of existing and proposed future high-performance electronic systems. Unique operational requirements have resulted in unusual designs in cooling systems. To meet requirements, compact electronics cooling packages have been designed, utilizing liquid-to-air, oil-to-air, air-to-air heat exchangers plus the use of electric-driven fans and flow control valves in the electrical controls and switches.

New and better means to provide individual component cooling are currently being developed, including new applications of the Peltier effect for controlling temperatures in transistors (to be covered in part 2 of this survey).



Electronic cooling packages can be grouped into two principal types: missile support equipment and missile carried equipment. While performing the same functions, it is obvious that cooling system configurations for the two types are considerably different. They range from the massive air-conditioning systems required for computer centers down to very small units for cooling infrared detectors.

As an example of the former, for the NORC computer center at Dahlgren Naval Proving Grounds, 50 tons of cooling equipment are contained in the computer system itself while 40 tons are required to cool the room in which NORC is installed. On the other end of the scale is the recently announced 8-ounce "min-IR-cooler" developed by **Arthur D. Little, Inc.,** of Cambridge, Mass., and currently being manufacturer by **United Aircraft Corp.'s** Hamilton Standard Division as an IR detector-cell cooler.

The systems and components produced by **United Aircraft Products, Inc.,** of Dayton, Ohio, as summarized in Table 1, indicate roughly how diversified electronics cooling can be. The table shows only part of the picture, since the UAP also produces the various valves, hand pumps and other components and accessories to complement its systems.

• **Missile support**—Missile support cooling equipment, either ground installed or airborne, is designed to reject heat from the fluid which is cooling the missile components during preflight checkout operation to the ambient heat sink—that is, the atmosphere or the ocean. Thus the fluid on the heat-sink side is usually air or water. On the heat-source side (missile), the fluids generally used are air, water, water-glycol, high-temperature synthetic oil, and inert gases.

• Checkout cooling—The extent to which air conditioning of systems can be carried probably is best demonstrated by those produced by **C. G. Hokanson, Inc.,** of Los Angeles. To provide reliability for missile systems during checkout, the company has developed a

TRAILER-mounted air conditioning production unit made by Hokanson for *Thor* missile bases. The "snorkel" was designed to place the air intake above the LOX level.

whole line of specialized equipment, providing "tailored atmospheres" for many different missiles systems and aircraft.

In all of these systems, temperatures are held within very close tolerances. A pioneer in this field, the company completed the largest single air conditioning installation in the West for rocket test facilities at China Lake Pilot Plant, Naval Ordnance Test Station, Inyokern, Calif. Among many of its major cooling systems built since that time, Hokanson test and production units are currently employed in the **Douglas** *Thor*, **Martin** *Titan*, **Northrop** *Snark* and **Lockheed** *Polaris*.

For *Thor* during final checkout, the Hokanson system essentially consists of three different operational units. They are all integrated and combined into one single mobile chassis.

• The measurement unit provides continuous heating and cooling during storage, standby, and countdown.

• The guidance portion of the system provides both heating and cooling but only during countdown.

• The third portion of the system is for the engine which provides heat during the countdown only.

Air connections to the missile are provided with four 150 ft.-long lines, including three inlets and one return.

In the measurement-cooling system, temperature is controlled by means of a thermistor sensor in the missile. The temperature control point is 90°F ±20. The unit can provide 15,000 BTU/hour cooling capacity and 25,600 BTU/hour heating. This portion of the system employs an air-to-air heat exchanger to lower refrigerant-compressor operating time.

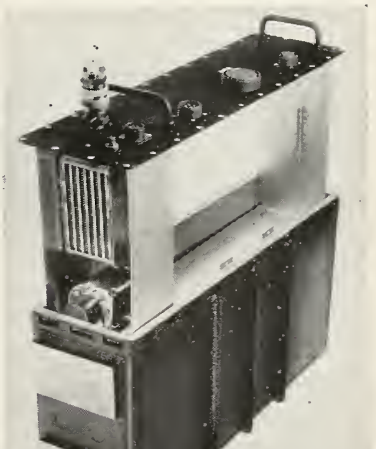
In the guidance-cooling portion of the system, fresh air can be delivered through the ducting at a rate of 800 cubic feet/minute against a static pressure of 13.5 inches of water. Again temperature is controlled by a thermistor sensor in the missile. An air blower supply is energized when the missile temperature reaches 80°F. The refrigerant cooling unit is energized when the missile temperature drops to 45°F. A warning system is actuated when missile temperature falls outside of the range of from 33°F to 124°F. Cooling capacity of this portion of the system is 36,000 BTU/hour.

In the engine-cooling portion of this system, fresh air input is at the rate of 1,000 cubic feet/minute against 13.5 in. of water. Control and regulation of temperature is initiated at the air conditioner with a range of from 40° to 200°F. Blower start and stop on lower speeds are actuated from the missile automatically. Again, a warning signal is produced if missile temperature goes below 5°F. This portion of the system can provide 225,000 BTU/hour heating capacity.

Heat for the air conditioning system is provided by a small electric fluid emersion heater which is divided into three-25kw stages. The fluid consists of a 50-50 mixture of ethylene glycol and distilled water. This is circulated to all three parts of the system by means of two pumps. More accurate temperature control is obtained through forced circulation by the dual pumps.

Reliability of the system is good. Specifications for the measurement unit provided for a 500-hour non-stop operating time, 100 hours at high speed and 300 hours at low speed in the engine unit, and 200 hours in the guidance section. The system is capable of 10,000 hours operation before the need for scheduled overhaul and its built-in test equipment permits monitoring of components not in continuous operation.

• **Missile cooling**—Because of the singularly unique operational requirements of the various systems, the environmental conditioning equipment carried in short-time flight has assumed practically every thermodynamic configuration possible. These requirements include flight time, whether in terms of minutes or hours, and an enormous, repetitive checkout period.



Installations have been designed by **Garrett Corporation's AiResearch Manufacturing Division**, a well-known leader in the field, utilizing only the thermal mass of the pre-cooled structure. Most installations however, said a company engineer, require the missile to carry an expendable evaporant in order to adequately cool the equipment. AiResearch ranks pure water, pure ammonia, and a solution of water and ammonia and water-glycol in that order as the most advantageous evaporants to use.

Water has the lowest thermal pressure and a good heat evaporation. Ammonia has low heat sink but high pressure. However, its storage and use is disagreeable to animal life.

Most problems which dictate unusual solution are high voltages in a small package requiring a high dielectric strength cooling medium and cooling specifications requiring close temperature control in order to minimize instrument drift. AiResearch said it

three approaches to radiation . . .

has maintained temperatures within ±1°F for electronic equipment dissipating from 10 watts to 10kw.

One unique feature of missile-carried equipment is that environmental conditioning equipment usually performs double duty as a cooling or heating system while providing structural mounting for the components being conditioned. For example, several AiResearch systems have taken the form of breadboards, container walls and other unique configurations. For this reason, they have vigorously attempted to educate electronic firms into consulting environmental-control firms at an early development stage in order that the environmental system may be feasibly designed into the package itself.

A typical example of an environmental conditioning system for electronic equipment involved a low total-head dissipation aboard a high-altitude missile.

AiResearch selected an open-cycle cooling unit because it is much lighter and less complex in operation than closed cycle systems. Net heat rejection was 85 w and it used an ammonia (NH_3) evaporant to cool nitrogen circulating over heat-generating electronic components. The system included an NH_3 storage tank, pre-cooler superheater, associative components. Specifications are shown in Table 2.

• Radiation cooling—In the missile-cooling applications above, energy transfer to the heat sink was by means of convection or conduction. This is quite satisfactory in flights of short duration. But, in space vehicles this transfer to the heat sink must be by means of radiation since the lack of an atmosphere removes the mechanism for convection and conduction.

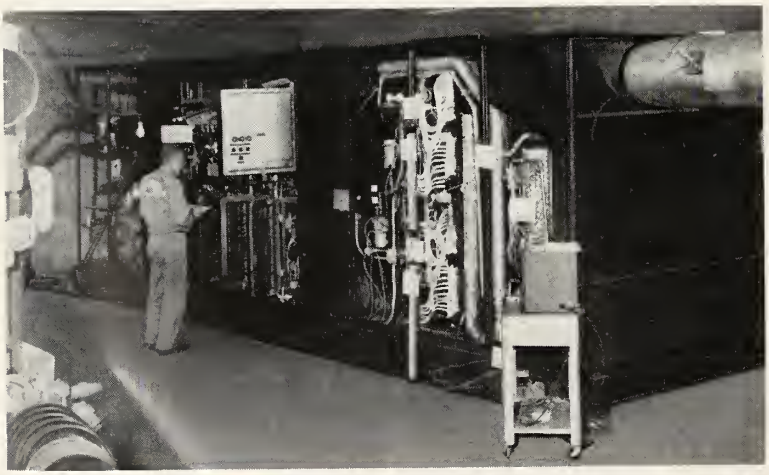
Thompson Products Div. of **Thompson Ramo-Wooldridge, Inc.,** Cleveland, in a report titled "Electrical Generating Equipment for Space Systems" has indicated that there are three possible (and practical) means of providing for this heat radiation cooling: employ a radiator designed to collect heat from the vehicle and its equipment and radiate its energy into space; employ the outer surface of the vehicle as a radiator; or, use a combination radiator and radiating vehicle skin.

Key to direct radiation cooling, according to Thompson, is the provision of equipment designed to withstand high operating temperatures. Their reason: thermodynamically, the higher the operating temperature of the equipment the greater the amount of heat transfer. Biggest advantage in radiation cooling would be the great savings in weight.

Space Technology Laboratories, Inc., of Los Angeles, recently revealed the development of new coatings for satellite skins that are capable of controlling internal temperatures in flight. Developed by Rudolf X. Meyer, a scientist in the company's Physical Research Laboratory, the coatings change color with temperature change such that they become light with an increase in heat and darken with heat loss. Thus they compensate for the temperature change by reflecting or absorbing heat radiation as required.

Meyer has found nearly 35 substances, either paint-like or plastic that have this "chameleon" ability. In using polymer compounds, he said use is made of the reversible transition from the "sol" state to the "gel" state as the temperature increases.



• **Heat exchangers**—An innovation in heat exchanger equipment is the heat transfer surface called "Inner-fin" developed and patented by **Dunham-Bush** of West Hartford, Conn., which is achieving marked success. The Inner-fin coils have proven to be one answer to the space and weight problem so significant in adapting cooling equipment to the relatively confined spaces associated with electronic equipment in missiles and aircraft.

The company has indicated that the use of their special coils has reduced necessary size by as much as 60%, still maintaining the same air and liquid pressure drops through the coil as obtained in standard finned tubes.

The exchangers are of all aluminum dip-brazed construction. Units finding direct application in the missile and aircraft business have been ethylene glycol-to-air, and oil-to-air heat exchangers. The Inner-fin construction has also been applied to Freon-to-Freon and air-to-air heat exchangers for airborne conditioning system components and ground support electronics cooling respectively.

Basic principal in the patented Inner-fin is the arrangement of longitudinal fins inside a tube in conjunction with outer fins. A small inner tube is mechanically expanded which locks the longitudinal Inner-fins in close contact with the inner wall of the outside tube and the outer wall of the inside tube. This type of construction provides greater surface area and smaller hydraulic radius. Thus the transfer of heat is more rapid. The longitudinal arrangements of the Inner-fin keep pressure drop at a minimum.

COMBINED air conditioning and water chilling units designed and built by Hokanson Co. in support of *Titan* program. It yields unprecedented amount of dry air.

Eyelets vs. Plated-thru Holes

A report on a comprehensive test in which all located failures were in eyeletted phenolic boards —last of two articles on printed circuitry

by Bernard C. Alzua, Jr.
Motorola, Inc.

PHOENIX—The most costly and me-consuming operation in the as-mbly of an electronic unit or chassis the hand wiring of the circuit. It is so the source of frequent errors, ecessitating costly inspection proce-ures.

The development of circuit boards id printed wiring has done much to leviate this situation. In fact, the high olume production techniques of cir-uit boards for radio and television assis is no longer a "state-of-the-art" ethod but more a mechanical process hich turns out quantities of 5000 to),000 units a day.

The use of circuit boards for mili-ry applications in missile and air-aft equipment, however, presents a ifferent set of requirements. Here the ctors of reliability and quality con-ol are paramount, and costs are sub-rvient to reliable performance. It is vth these high-quality, high-reliability pes of boards that this article is con-rned.

• **Reliability factors**—The cost of inted wiring is high, especially when liability is a "must." The cost of the ost expensive board, however, is latively little when compared to the st of a reject board that is completely embled and contains 75 or more ounted components.

To the Army Ordnance Missile mmand, Huntsville, reliability means "the positive assurance that the weapon will function effectively whenever required." The military demands that reliability be achieved during the R&D phase of each weapon system through quality-assurance and quality-control programs.

Accordingly, exhaustive flight testing is the rule in current programs. For example, an average of 230 individual measurements are obtained during each flight of the *Redstone* missile.

• **The controversy**—One of the most important debates relating to reliability of circuit boards is over the use of eyelets or plated-thru holes. At **Motorola's Western Military Electronics Center** in Phoenix, our Reliability and Components Group has been conducting a lengthy and comprehensive evaluation of the relative merits of each.

In the past few years, many users of printed boards have had so much trouble with plated-thru holes that they want no part of them in the future. We have found grounds to indicate that the trouble is not so much with the basic technique as it is with such deficiencies as poor quality holes, contamination and insufficient copper in the holes. It will be shown that we have, indeed, used the technique of plated-thru holes in several high-reliability applications with outstanding success.

A missile, rocket, or aircraft has numerous printed wiring boards—indicating that hundreds and thousands of eyeletted or plated-thru holes would be involved. Without attempting to be complete, the following report on comparative tests presents the most significant results obtained thus far.

Before these tests were made, several versions of wall thickness of plated holes were made and analyzed. Failures were located and their causes traced. We finally struck upon what we feel is an optimum thickness, and this was used in the test program.

• **Test program**—The objectives of the performance tests were:

1) to determine the relative ability of properly installed and soldered eyelets and of properly plated holes to maintain electrical continuity through epoxy glass boards; and

2) to evaluate, in the same manner, properly installed and soldered eyelets in XXXP phenolic printed wiring boards.

• **Environmental tests**—Briefly, eighteen epoxy glass eyeletted printed boards and three epoxy glass plated-thru hole boards (each board having a total of 100 holes) were subjected to the following environmental procedures:

1) thermal cycling, 15 cycles from -65°C to 125°C in air;

2) vibration, 10g 20—2000 cps and at their resonant frequencies for one hour, while carrying 30 ma-dc;

3) humidity exposure 91% RH 70°C, for ten days while carrying 30 ma-dc; and

4) immersion-vibration cycling, three cycles, each compromising three days of water immersion at 70°C followed by the vibration cycle.

Three standard eyelets were chosen for the tests because they fell within the average and standard hole sizes. Type 1, Circon #CE-34 was tooled to obtain serrated flanges on both sides. Type 2, American Brass #E-3700, was tooled to obtain funnel flanges on both sides. Type 3, United Shoe #S-5862, was tooled to obtain a rolled flange on one end and serrated flanges on the other.

Three hundred plated holes, gold finish, were compared with the same quantity of each of the eyelets just mentioned.

An equal number of phenolic boards was eyeletted and all of the boards included in this test were soldered and fitted with leads in the following manner. Approximately one-quarter (25)

The author is manager of the Printed Circuit Facility at the Motorola Western Military Electronics Center, Phoenix, Ariz. A mechanical engineer, he has an extensive background in photography and photographic methods. Formal training: University of Arizona, the Kodak Institute, Rutgers University.

cracks between flange and solder . . .

of the holes in each board were prepared with each of the following variables:

1) Holes were filled with 60/40 solder from both sides.

2) Holes were filled with solder from one side using the blind technique.

3) Component leads were inserted and soldered from both sides.

4) Component leads were inserted and soldered from one side.

• **Comparative results**—The comparisons that can be made from our test results obtained to date are shown in Figs. 1 through 6.

From Fig. 2 it can be seen that the most significant number of failures occurred in funnel-flange eyelets installed in phenolic boards.

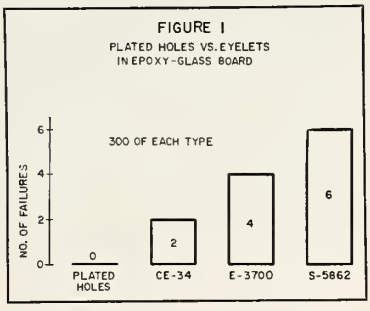
All located failures were on eyeletted phenolic boards. Microscopic examinations showed that cracks had developed between the eyelet flange and the adjacent solder. Similar cracks have developed on many other eyelets in both XXXP and epoxy glass boards which have not yet failed.

All failures of eyelets in epoxy glass boards were classified as unlocated because, though definite circuit interruptions had occurred during vibration, the continuity was restored when vibration ceased.

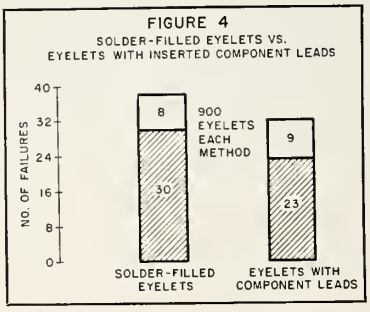
Specimens prepared with blind soldering techniques had more failures than those that were soldered from both sides.

At present, we have found that G-10 and G-11 laminate series have been the most satisfactory to use on military type printed boards, particularly if the application involves a missile or aircraft device.

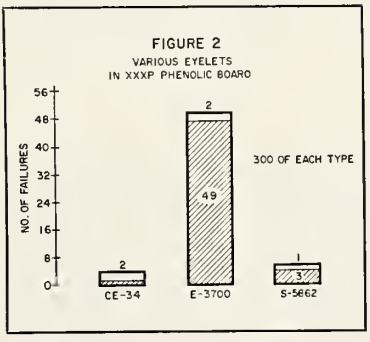
As far as printed-board materials for the future are concerned, I believe that the industry will gradually go in the direction of boards that can withstand higher temperatures and shock.



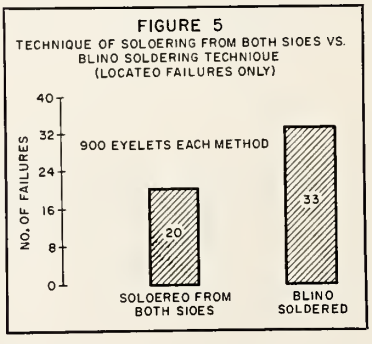
Of the several methods to produce a printed wiring board, we have found the copper-clad and etching method to be the most reliable. Remember that I am considering military-type boards only.



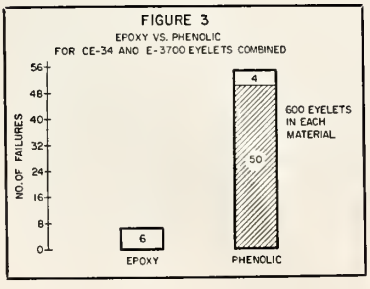
Some other methods involved have shown signs of potential breakdown either in a cold-copper joint, or erratic adhesion to the laminate and other fabrication defects.



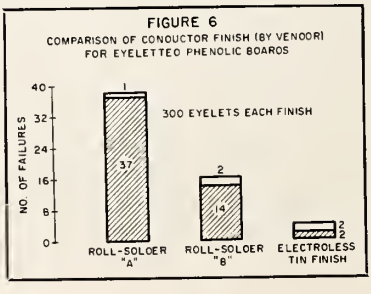
To produce a high-quality military-type printed-wiring board is definitely a "state-of-the-art" program and shall continue to be so as long as reliability is the key to the success of missile/aircraft vehicles.



TEST RESULTS



Light areas show unlocated failures; shaded areas show located failures.



ITT Monitor Guards Launch Communications

CHICAGO—An automatic monitor to watch over and switch communication lines in case of trouble has been developed by **International Telephone and Telegraph Corp.** for the *Atlas* project. Designed primarily to assure uninterrupted voice communications during missile launches, "Commswitch" has possible future applications in such areas as teleprinter circuits, telemetry, and stock tickers.

In its present application, the unit "listens" to a phone conversation and automatically switches to an alternate line in case of excessive noise, change in transmission characteristics, distortion, or line break. Maximum operating distance—either on landline or equivalent microwave relay—is 60 miles.

Circuit Elements Mounted in Module

MENLO PARK, CALIF.—A new "window frame" technique for mounting transistor circuit elements in a compact module has been devised by **Stanford Research Institute.**

Two sets of eight elements are mounted back to back in the hinged frame and one connector serves all 16 circuits.

RAF Thor Base

(continued from page 11)

rons, Nos. 1 and 2 got individual training in the United States and crew training actually on the job in England. Nos. 3 and 4 got or are getting individual training at the U.S. plants and crew training at Vandenberg AFB, Calif. All of the crews will rotate back to Vandenberg for practice firing training.

In discussing the entire RAF missile training program for the *Thor*, Duncan Sandys, British Minister of Defense, said that he was immensely impressed by the speed with which it has been carried on and he paid especial tribute to the USAF and to the Douglas training program. He thought the *Thor* tests carried out in the States proved that it was becoming more reliable every day and that we were rapidly approaching the day when it would be regarded as a normal operational weapon, much as today's bombers are regarded.

Sandys referred to the missile, incidentally, as a successor to the manned bomber, although his RAF leaders feel —as do most USAF generals—that it now only complements the manned aircraft and will do so for a long time.

• **Made in Britain**—As a follow-on to the *Thor*, Defense Minister Sandys said the RAF has coming up the *Blue Streak*, a 2000-plus-mile missile, 10 feet in diameter and about 60 feet long, roughly the size of the *Thor* but more powerful. It will also be used for scientific experiments, Sandys said, adding that the Woomera Test Range had been extended to test it. Making the one-stage *Blue Streak* are **de Havilland Propellers Ltd.** and **Rolls Royce,** with **de Havilland Aircraft** and **Sperry Gyroscope Ltd.** as associated contractors.

Air Vice Marshal Gus Walker, the RAF's new chief of information, came up with a new definition of an effective deterrent force for a group of American newsmen recently. He said:

"When Russia sets up a war game against the West, plays it and *loses*—then you have an effective deterrent."

The World War II RAF hero also noted the part the British Bomber Command plays in this deterrent force. It is "several times" as large as the SAC contingent stationed in England, he said, can carry either British or American nuclear bombs and—due to its forward location—would be the first manned force to strike the Soviet Union in case of war.

Vehicle Requirements

(*continued from page 20*)

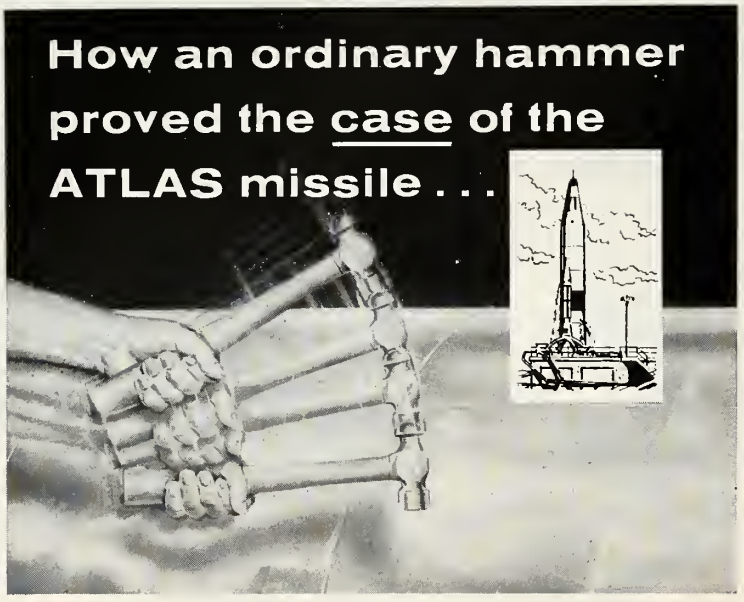
with a nonstop range of approximately 250 miles. The range and speed both decrease as the travel conditions become unfavorable with increases in grade and/or rolling resistance. The range may be readily increased, if desired, by increasing the fuel capacity.

• Consideration was given to the various U.S. state highway regulations, since the vehicles will travel on the highways. For the heavier missiles, it will be necessary to upgrade, by special permit, the highway size and weight restrictions. Farm and construction equipment criteria will be used. The study will include separate delivery of the missile and booster to reduce G.V.W. and size.

• The chart on p. 19 is a summary depicting the principal state highway restrictions currently in effect. The summary is severely condensed, since the individual state highway regulations would fill several publications.

• Eight feet is the maximum prevalent vehicle highway width allowed today. With special permit, excess width allowance is granted by the various states to farm, earthmoving, and construction vehicles. In general, 12 feet is the maximum width allowable for mobile equipment subject to rail shipment, due to the restrictions of tunnel and multiple, parallel-track side clearances. Certain of the FMC concepts have exceeded the 12-foot width to obtain other design advantages.

• Height limitations vary from 12'6" to 13'6" in the various state highway laws. The height limitations are established from subway and underpass dimensions, public utility lines, traffic signal, electrolier, etc., clearances. Careful consideration has been given to the extreme length required for the transporter.



• **Shock effects**—The final problem that we will consider is the effect on the missile of shock imparted from the road as the wheels pass over various bumps or obstacles. At our high-speed test track and cross-country test course of FMC's Ordnance plant, we have performed tests to determine the shocks imparted to missiles under various transport situations.

During the *Navaho* program, the equipment shown in photo (p. 18) was instrumented for shock testing and tests were performed for highway transport. At speeds up to 15 miles per hour on our paved test track, the maximum shock load was .230; however, this was under the equivalent of good highway conditions.

We recently completed test for a 14,000 lbs. missile load equivalent being carried on a tracked vehicle. Under normally severe cross-country conditions it was found that a maximum of 3 g loads are to be encountered. Under severe tests which went beyond the realm of reasonable usage, shocks of 5.8 g were encountered for periods up to 20 mili seconds.

In summary, it can be seen that there are many factors to be considered if a large mobile missile system is to be designed. A careful study must be completed to predict operational requirements before military characteristics can be written for transport equipment. Predicting overly severe conditions will lead to overdesign—with increased cost and weight. On the other hand, if too optimistic views are entertained, the system will fall short on performance when severe conditions are encountered.

It can be readily seen that one important factor is relating the missile's physical characteristics to operational requirements for mobility. If the missile and its components cannot withstand the expected shock loads, then despite the mobility that is inherent in the equipment, the system will not function when required at a critical time.

The body of the missile, essentially one big fuel tank, is similar in principle to an inflated football. Convair-Astronautics broke new ground in missile design by developing a super-strong structure with a comparatively thin stainless steel skin to keep weight to a minimum. This stainless steel skin is so thin that the interior has to be pressurized to preserve the shape of the body as propellants are consumed in flight, or when the missile is being transported on the ground.

Some critics, however, thought the body was too fragile—"You could dent it with a hammer." So, recently, when the Scientific Advisory Board, engaged in a re-evaluation of all missile programs, arrived at Convair-Astronautics to take a reading on the ATLAS, they found that Convair had thoughtfully placed a number of hammers within easy reach of a finished missile. "Go ahead, bash it," invited Convair. The SAB members swung lustily. *Not a dent was registered*, for, although the walls are thin, the stainless has a minimum tensile strength of 200,000 psi.

This stainless steel skin material, supplied by Washington Steel, required extremely close control of mechanical properties and gauge tolerance which are regularly produced through Washington Steel's long experience with precision rolling equipment.

soviet affairs . . .

By DR. ALBERT PARRY

The Red version of Project *Mercury* . . .

how well has it fared compared with the choice and training of our seven astronauts? The Soviets say and publish very little on their part in this momentous race. They talk instead about the training and flights of their twelve dogs and one rabbit.

Yet, Soviet spacemen-in-training do exist . . .

We hear that Moscow did sometime ago select five men for such conditioning. One of the five has since been killed in an accident, the nature of which had not been revealed. All five were World War II flyers, decorated for their feats in air combat. This much was told by Soviet space-medicine experts to our Brigadier General Don Flickinger, medical assistant to the commander of the U.S. Air Force's Air Research and Development Command, on the general's recent trip to Moscow.

Older than Project *Mercury* airmen . . .

Russia's would-be-spacemen were perhaps not as carefully selected as our seven candidates. General Flickinger concluded this, in part, from a certain surprise evidenced by the Soviet space-medicine men to whom he talked: they voiced their interest in the fact that the seven U.S. astronauts had particularly high IQ's. Was this a requirement? they asked. No, our general replied, it just happened that the American candidates who passed the stiff requirements of psycho-physical fitness have those high IQ's as well.

As to the Soviet yardsticks . . .

for their spacemen, it may be argued that if the Soviets had similar tough standards of psycho-physical fitness for their candidates, the latter might have also possessed keen intelligence and the Moscow doctors would not have been surprised by our men's IQ's.

On the other hand, we may speculate that the Soviet spacemen are not only flyers but have also been specifically trained in various advanced astro-sciences. This would make them almost invariably older than our men, and thus spared anything like our exacting standards of psycho-physical fitness applicable to younger men only. Yet, the older Soviet spacemen may be every inch of their brain as intelligent as our younger ones. The Moscow doctor's interest in our men's IQ's may be due to the fact that in Russia generally, IQ tests are seldom, if ever, used.

Soviet interest in *Mercury* is high . . .

This is seen particularly from the recent article in *Sovetskaya Aviatsia* on American methods of selecting and training of "cosmonauts," written by Dr. V. Borisov, a space-medicine expert.

An American film shown in Moscow recently was judged as of great value to Dr. Borisov and his fellow space-medicine men. This was the movie brought by U.S. delegates to the May 25-June 1 conference of the International Aeronautical Federation held in the Soviet capital. Dr. Borisov wrote that during the period of weightlessness, shown in the film clearly by the floating of a few unattached objects in the plane's cabin, the American flyers who were being tested "worked on a special installation with a large number of buttons and levers"—and the Soviet viewers obviously admired our flyers' movements "which were quick and well coordinated."

Particular impression in Moscow was made . . .

by these U.S. ways to overcome weightlessness: Item One—training an astronaut to float in the cabin during his weightlessness. This floating, Dr. Borisov observed, was done "dexterously," the floater's cycle of movements "greatly resembling the ordinary movements of a swimmer." Item Two—the use of special shoes with magnetic soles. Item Three—combatting the difficulty of drinking liquids while weightless. Dr. Borisov wrote approvingly of special vessels from which U.S. astronauts squeezed water directly into their mouths.

— review —

Forty-two years ago the Bolshevik leaders of the Soviet Union faced a hostile world with an air force limited to some 300 obsolescent foreign planes, a few Ilya Muromet bombers and a lack of spare parts.

Today the Soviet Air Force—with its bombers, its tactical fighters, its troop-carrying jets, its ICBM's and IRBM's—is the terror of the earth.

The detailed story of how this has come about is the core of *The Soviet Air and Rocket Forces* (Praeger, $7.50), an excellent new symposium edited by British Aerospace Expert Asher Lee.

But Lee, a former British intelligence officer and wing commander, and his fellow writers also do much more. Along with one of the best histories of modern Soviet air power to date, they also provide a provocative series of chapters which explore the Russian military mind and its effect on air strategy and tactics. In the end, a remarkably clear picture of the future of Soviet air power emerges.

Undoubtedly one of the most important conclusions that can be drawn is that if Lee and his associates are correct the United States will be most foolish indeed to write off the threat of Soviet manned bombers at least anytime in the next decade.

The book brushes aside Soviet Premier Khrushchev's statements that the bomber belongs in a museum as so much propaganda.

At the same time, Lee & Co. raise an even more ominous threat: The missile-launching Soviet submarine.

Soviet work on launching long-range missiles from submarines is, unlike the U.S. *Polaris* program, no comparatively recent development. Instead, it dates back to work by German scientists at Peenemunde in 1945.

So far, Russia has been developing two series of submarine missiles: the *Golem* and *Komet*, designed for firing from submerged submarines.

Lee and Robert Stockwell state in a chapter on Soviet missiles that the Soviet Union today probably has only a few dozen submarines capable of firing long-range missiles with any accuracy. However, they add: "With each year that passes the long range attacking power of Soviet submarines will become more important to overall Soviet strategy."

Finally, another warning from this many facted book is based on Russia's growing fleet of jet transports. These would be capable of rapidly transporting large numbers of Red Army units to distant points for seizing key positions—vital in a future atomic war.

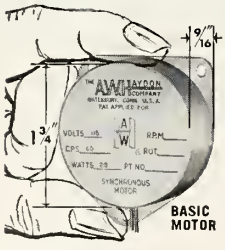
—moscow briefs—

by Dr. Albert Parry

In summarizing the NATO's plans for rocket bases, two Soviet officers write in *Krasnaya Zvezda*, the daily organ of the USSR's Ministry of Defense, that "by the end of this year the United States proposes to implement 35 rocket bases in the countries of the NATO"; also that at the present time there are stationed in Europe 30 NATO divisions armed with missiles, which number by 1963 is to be increased to 100 divisions. The authors of the *Krasnaya Zvezda* article, Colonel V. Nagrebetsky and Lt. Colonel A. Kashcheyev, express their alarm and indignation over the increase of rocket armaments in Great Britain, Italy, Greece, and Turkey. They refer also to the American "pressure" on Norway to accept nuclear warheads for her missile weapons. In addition, they dwell on U.S. efforts to expand "the building of American rocket-nuclear bases and storehouses" in Canada, and to change the role of Canadian infantry in Europe by arming these troops with rocket-nuclear weapons "so as to enhance the attacking capacity" of Canada's foot-soldiers.

In another issue *Krasnaya Zvezda* reports that West Gemans are planning to have nine nuclear-rocket divisions, with 26 missile-launching sites and 288 rocket weapons "which will be delivered from the United States." *Krasnaya Zvezda* also estimates that nearly 1000 West Germans are now being trained in the United States to handle "military rockets with atomic warheads," and that some 2000 such West German officers and soldiers, completing their missile training in America, have already returned home, ready for their new duties.

The "militarization of the 49th state" is described in compact but ample detail by Lt. Colonel P. Kondrat'yev in *Sovetskaya Aviatsia* in a special article devoted to Alaska. He calls the newly admitted state "the springboard of American aggression in the Arctic . . . aimed to attack the Soviet Union and other Socialist countries." In his listing of U.S. bases and arms in Alaska he mentions the presence of the *Falcon* as a notable operational Air Force air-to-air missile.



• **Rocket lit. watched**—U.S. and other Western literature on rocketry is being carefully watched in Moscow by the staff of *Izdatel'stvo Inostrannoi Literatury* or the Foreign Literature Publishing House, which, as ever other publishing establishment i Russia, is of course owned and run b the Soviet government. Books an articles deemed to be most importan are selected for translation into Russia for early Soviet publication. An out standing project is a nine-volume serie to which the Moscow editors gave th inclusive title of *Foundations of De signing Missiles*. The first of the nin books came out in 1958; the secon has just been published in Moscow.

This volume II is made up of trans lations from the English of articles b several authors, under three categories "Research of Operations," "Warheads," and "Launching of Missiles." It ha drawn a detailed review in *Sovetskay Aviatsia* by Lt. Colonel V. Tyurnin o the Soviet engineering troops, who i also a candidate of the technica sciences and holds a teaching post a *dotsent* in one of the academies. H pays particular attention to the book' data on ground-to-air missiles; also praises the "original and very simpl method of defining areas of possibl attacks by missiles" as explained i the volume.

But a greater part of the review i belligerently negative. Lt. Colone Tyurnin criticizes the "low scientific level" of the book, its "inexact expres sions and vague definitions," its gener alizing about missile warheads with out giving more precise details abou them, its paucity of information on re sistance of materals used in missil making. The Soviet reviewer com plains: "The small amount of valuabl data contained in the book is dissolve in the many pages of little or no worth." He also rebukes the Soviet translator and editors for preserving intact th original author's Western political viev of the Cold War. The *Sovetskay Aviatsia* writer warns the Moscow editors and publishers of Western litera ture to cut and prune while translating in sum, to be more "discerning."

• **Future sciences**—Astrogeology astrogeography, and astroclimatology are the sciences of the future, the foun dations for which are being laid by Soviet savants right now, according to I. Zabelin, a candidate of the geographic sciences writing in *Komsomolskaya Pravda*. The three new branches of human knowledge are concerned with novel methods of probing into our planet's structure and climate by comparing them with those of the Moon Mars, Venus and other planets. The writer names B. L. Lichkov and G. N. Katterfel'd of Leningrad and M. V. Stavos of Dnepropetrovsk as three of the Soviet scientists in the forefront of these new interests and techniques.

NAA Help Wanted Ad Probed by Congress

A **North American Aviation** newspaper advertisement seeking a "military advisor to advise-counsel-report on high level management on military matters as they apply to long-range planning . . ." was poorly worded, a company official conceded to House investigators last week. The ad in the May 7 Wall Street Journal also said applicants should be "personable with high degree of speaking and writing ability" and have an Air Force colonel or Navy captain background, preferably with Joint Chiefs of Staff experience.

W. H. Yahn, vice president and general manager—NAA Columbus Division, in response to questioning told the Hébert Armed Services Investigations Subcommittee Joint Chiefs experience was sought because the company wanted a man who "plans ahead" and who could anticipate military needs by 5 to 10 years. The ad drew 70 responses, Yahn testified, adding that three men were under consideration. In an exchange with subcommittee counsel John Courtney, Yahn said the cost of the ad was charged to company profits instead of to allowable overhead on government contracts, and was probably an error. If that was true, said Courtney, NAA appeared to be promoting its own business with government funds.

Another witness, Gen. Omar Bradley, chairman of the board of the **Bulova Watch Co.** and head of the company's R&D laboratories, said no one in or out of the service had ever attempted to pressure him when he was a five-star general. Noting that several other witnesses had testified in the same vein, Rep. Porter Hardy (D-Va.) commented the investigation may be a "tempest in a teapot." But Chairman F. Edward Hébert (D-La.) said it was still the subcommittee's duty to air fully charges that firms were employing ex-military men to influence defense contract awards.

Ablating *Atlas* Recovered

The *Atlas* re-entry vehicle recovered July 21 after a 5000-mile flight down the Atlantic Missile Range was the biggest yet flown by the U.S., according to the **General Electric Co.**

Vehicle was more than 12 feet long, an elongated cone with a rounded nose constructed of ablation materials. A spokesman of GE's Missile and Space Vehicle Department in Philadelphia said the vehicle came through the test in "good shape." The cone carrying data equipment in the warhead compartment is described as one of a series of experimental models leading to a second generation ablating type ICBM operational re-entry vehicle. Recovery system, including after re-entry parachute deployment, balloon support after impact and radio-flashing light-dye marker locating devices was by **Cook Electric Co.,** Chicago.

Sylvania Data Facility Size Doubles in Year

Sylvania Electric Products Inc. is adding another 67,000 square feet to its Data Systems plant, Needham, Mass., where it is developing data processing systems for BMEWS and MOBIDIC. The new addition, to be completed by Sept. 1, will bring the plant size to 212,000 square feet—more than double the original size when Sylvania moved in 12 months ago . . . **Kurz & Root,** Appleton, Wis., producers of electrical missile support equipment are opening a manufacturing facility in Burbank, Calif. . . . A new firm—**Production Machinery Inc.**—has been organized at Des Planes, Ill., to import and market West German metalworking machinery. . . . **Applied Electronics Corp.** of New Jersey has moved into a 4000 square foot plant in Metuchen, N.J. . . . and last week, **Reeves Soundcraft** stock moved up to the New York Stock Exchange for trading . . .

Purchase of **Applied Science Corporation of Princeton,** N.J., for $3.8 million has been contracted by **Electro-Mechanical Research Inc.,** Sarasota, Fla. The agreement is still subject to stockholder approval. Both firms are in telemetry field.

Corvus Is Launched Successfully

POINT MUGU, CALIF.—*Corvus,* an air-to-surface missile for use by carrier-based Navy aircraft, has been flown successfully for the first time at the Pacific Missile Range test center.

The Navy, in announcing the July 18 firing, ended almost two years of speculation with the announcement that *Corvus* has a pre-packaged liquid engine. However, the propellant ingredients were not disclosed. Before the announcement, it had been generally believed that *Corvus* has a solid propellant system.

Temco Aircraft Corp. of Dallas, Tex., has the contract for development. **Thiokol** is providing propulsion. *Corvus'* guidance system will home on enemy radar. **Texas Instruments** and **W. L. Maxson** are working on electronic components.

The test vehicle was fired from a Navy A-40 Skyhawk jet fighter over a sea test corridor just west of here against an undisclosed target. *Corvus* is designed for attacking heavily defended areas, including surface ships.

Hearings Start on Nuclear Plane

by Erica M. Karr

WASHINGTON—Political, economic, military and technical questions are all wrapped up in development of the nuclear-powered aircraft, the Joint Atomic Energy Committee was told when it reviewed at public hearings, as M/R went to press, the 13-year old ANP program. This was the first public hearing after almost 50 executive sessions in the last 12 years.

The political question simply stated is: "What would be the effect of a Russian flight of a nuclear-powered aircraft on world politics?" Russia's big 6-or-8-engined Bounder, which has been seen flying, is—or could be—a prototype for a nuclear-powered aircraft.

Economic questions are also relatively simple. Estimates by Dr. Herbert York, Director of Research and Engineering at the Pentagon, indicate that it may cost as much as $10 billion to develop a weapon system. Congress and the American people will have to decide whether the investment is worth making. So far, over the last 13 years about $1 billion has gone into development of the nuclear power plant.

• **Varied potential**—From a military standpoint, what would the investment buy? Its potential for many uses has been discussed frequently. Basically, however, the Air Force—which has supported the program over the years—conceives of CAMAL (continuous air alert and missile launch and low-level penetration) as providing the post-attack reconnaissance capability not available from any other type of equipment. Without it, the claim is made, the U.S. would be blind once an all-out attack were launched.

Other potential uses include continuous air alert (obviously outside the borders of Russia) to gather information to be used by *Polaris* submarines, *Minuteman, Atlas* and *Titan* bases after an attack is launched, or as a virtually invulnerable mobile missile warehouse/launcher. The Air Force feels such an airplane has as much ability to hide in the vast expanse of air as a *Polaris* submarine has to hide in the ocean.

• **Hold-ups**—What are the technical questions holding up the program at this time? Perhaps the most important one is the engine. The Air Force position is that the direct cycle reactor under development at **General Electric** is far enough advanced at this time to warrant building two prototype aircraft so that problems of logistics, ground handling, crews, ground and air safety can be proved out while the engine is perfected or improved. This is under the current AF doctrine of concurrency; The Air Force estimates that if a flight test vehicle program is initiated now, actual flight reactor tests could get under way within 3½ to 4 years.

Actually, the current reactor is a relatively crude one with its metallic core. A later reactor at GE would have a ceramic core follow. The other engine (indirect cycle) at **Pratt & Whitney** is merely described as a more advanced concept. The Navy wants a turboprop engine. AF is talking in terms of a turbojet.

The Pratt & Whitney engine is two to three years behind the engine a GE. Here the question is: Does th U.S. want to buy time or does it wan to wait for the engine?

Air Secretary James Douglas an Air Force Chief of Staff Thomas D White are urging the fly-early program They argue that the U.S. must start t fund the flight program now if an oper ational aircraft is to be available whe it is needed.

"You don't start with your fina product," said one official in the pro gram. "You start with your curren capability."

GE Sees Promise in 'Tunnel Diode'

SCHENECTADY—A significant new development in semiconductor devices —the "tunnel diode"—shows promise of outstripping its older brother, the transistor, in many applications. **General Electric,** at work over a year in a concentrated research program, has just announced that limited quantities of experimental samples will be available within a few months.

According to Dr. Guy Suits, GE v-p and director of research, the tunnel diode offers considerable advantage over transistors in several areas. First, energy motion within the device takes place at the speed of light in contrast to the relatively slow speed of electrical charge carriers in transistors. The resultant high-frequency response will allow switching speeds 10-100 time faster than transistors. Also, oscilla tion frequencies higher than 2000 m have already been obtained; 10,000 m are expected in the near future.

The tunnel diode—which operate on a different principle and is smalle than a transistor—is little affected b environmental conditions. It operate at 650°F and is more resistant t nuclear radiation by a factor of 100 to one.

Dr. Suits predicts that before lon the device should find its way int many applications including high-spee computers, television and communica tion equipment, nuclear controls, satel lites and space vehicles.

COMPLETE transmitter, no larger than a half-dollar, contains one variable and tw fixed ceramic capacitors, a coil, and tunnel diode (in "can" at center of device)

propulsion engineering

Petroleum industry arguments . . .

which urge long-range plans to continue use of petroleum-derived fuels instead of jumping into synthesized "pure" compounds emphasize the high performance of available liquid hydrocarbons, their low cost and abundance. The whole industry's argument is summed up by M. E. Conn and W. G. Dukek, **Esso Research and Engineering Co.** Their argument makes sense. It is unfortunate that they represent a major petroleum company, as this might be viewed as detracting from the impartiality of their comments. However, regardless of their industry affiliation, what they say will find ready agreement among chemists, missile designers, military planners, and economists.

Only the coal industry can object . . .

to the Conn-Dukek proposal to meet our future missile fuel needs by deriving hydrocarbon fuels from petroleum streams. This eliminates coal tar starting materials and intermediates that are being examined as sources for the so-called "pure chemical" fuels. The end results often will be the same: Commercially acceptable chemical compounds which could have been derived either from coal or petroleum. The difference is that by processing petroleum streams, chemists eliminate many steps and cut costs. Besides, the petroleum fractions already are passing through refineries, and some of them even are wastes.

Strongest point in the argument . . .

is that there really is a difference between theoretical performance and attainable performance of fuels. Some inorganic propellant systems offer higher theoretical impulse and heat content than the polycyclic naphthenes that Conn and Dukek discussed at the recent Society of Automotive Engineers meeting in New York. However, they point out, the attainable performance depends on many other factors: thermal stability, vapor pressure, combustion characteristics, viscosity-temperature relationship, density, specific heat. Also, ease and safety of handling are important factors to consider in choosing a fuel. Conn and Dukek say—and, by their own means, prove—that liquid hydrogen is all-around best, hydrocarbons are in second place, next down the scale is hydrazine. Metal slurries and metal hydrides are tied for the bottom of the list.

Logistics arguments . . .

are just as impressive as are the arguments relating to performance, handling ease, etc. Conn and Dukek say these arguments are even more important. They point out that the Air Force believes that within five or ten years its requirement for high performance fuels for air-breathing supersonic missions alone may reach 100 million gallons/yr. We'll need 25 million gallons of liquid rocket fuel just for testing and development by 1965. The advent of multi-million pound thrust engines, using fuel at 10,000 lb/sec., could more than quadruple the needs. The Esso R&E scientists believe that only the nation's huge petroleum refineries can guarantee a steady supply of fuel at low cost.

The picture is not complete . . .

without a look at the major disadvantage—if the word applies—of the polycyclic naphthenes. Since these are actually petroleum fractions cut out of refinery streams, and not compounds synthesized especially for the purpose, the petroleum industry cannot guarantee absolute uniformity or constant quality. However, test procedures are available to match the fuel to the engine or mission. Besides, Conn and Dukek point out: "Even the basically superior uniformity of pure compounds may be difficult to realize in practice." If enough meaningful specifications are developed and applied to manufacturing operations, they believe the batch-to-batch uniformity or petroleum fraction fuel can be controlled to a sufficient degrcc.

Exceptional openings for **ENGINEERS** and **SCIENTISTS** in the field of **ELECTRICAL WIRE** and **EQUIPMENT**

Boeing, a contractor on the Minuteman solid-propellant ICBM and an industry leader in the development of advanced weapon systems, offers engineers and scientists a number of outstanding openings in the field of electrical wire and equipment.

Challenging, long-range assignments are available to qualified applicants interested in coordination and optimization of design requirements, coordination of design with test laboratories, compatibility, reliability and integration of wire and conduit, junction boxes, switch panels and all components and major subsystems of the electrical power distribution system as related to missile programs.

At Boeing you'll enjoy the benefits of a dynamic career environment that is conducive to rapid advancement and deeply rewarding achievement.

missiles and rockets

AN AMERICAN AVIATION PUBLICATION

1001 VERMONT AVENUE, N. W., WASHINGTON 5, D. C.

vest coast industry . . .

By FRED S. HUNTER

Douglas Aircraft Co.'s ALBM (air-launched ballistic missile) contract is a study contract, but there is little doubt it will develop into a research and development contract before too long. Personnel assignments made to the project make it plain Douglas is confident R&D funding will follow without mishap. J. A. Gorgenson, heading up the program, has been appointed weapon systems manager, reporting directly to Leo A. Carter, vice president and general manager of the Santa Monica division. Both Gorgenson and Victor E. Crosley, assistant weapon systems manager, were brought over to Santa Monica from the El Segundo division originally to participate in preparation of the proposal which won the study contract for Douglas.

Strong projecting engineering group . . .

also has been established by R. L. Johnson, Santa Monica division missiles and space systems chief engineer. J. C. Solvason, former project engineer on the *Sparrow* series, is chief ALBM project engineer. His aides: H. E. Bauer, a former *Thor* project engineer, on missile aspects; S. L. Gehring, with *Sparrow* II and *Thor* experience, on missile support equipment; C. E. Starns, who also has a *Sparrow* background, aircraft support.

One of Hughes Aircraft's most popular . . .

vice presidents, Clarence Shoop, is demonstrating a remarkable capacity for assuming added responsibilities. Shoop began his career with Hughes in 1947, mainly in the flying end. One of his early jobs was chief pilot. As Hughes Aircraft expanded into electronic activities, he became director of aircraft operations and flight test. Subsequently, he was put in charge of product reliability and elected a vice president, but still retaining flight test. The other day, when R. M. Russell resigned as vice president-sales and manager of the international division, Shoop took on the international division and on top of his other duties became responsible for Hughes Aircraft's activities outside the U.S. And in addition to wearing three hats at Hughes, he is air chief of staff for the California Air National Guard, an administrative job carrying the rank of major general.

For the sake of secrecy the U.S. may test . . .

some of its missiles at the Woomera test range in Australia. We've had a team of experts there looking the place over. Situated in the Great Desert of Western Australia, the Woomera range was recently extended to a length of 1250 miles, and next year Britain will use it to test its 1500-mile *Blue Streak*. Cape Canaveral is close to a populated area and on flat ground. Vandenberg and Point Arguello are better, but the other day a cabin cruiser with a dead engine drifted within the three-mile limit off Arguello without being detected. A railroad cuts through Vandenberg and various roads bisect the region.

Only real secrecy the U.S. has ever . . .

achieved in rocket firings was with three Project *Argus* nuclear rockets fired from a Navy ship and exploded more than 300 miles above the South Atlantic last summer. Partial secrecy was managed in firing hydrogen devices above Johnston Island in the Pacific, but the flash was visible in Honolulu. In contrast, Russia's launching areas for long-range missiles are at Kyzyl Kum, near the Aral Sea, and at Kapustin Yar, 60 miles south of Stalingrad. Known impact areas are those east and north of Yakutsk in northeastern Siberia and in the Anadyr region even farther east.

They let no grass grow under their feet . . .

at **Lockheed.** No sooner had Lockheed acquired the **Puget Sound Bridge & Dredging Co.** than its missiles and space division brought the new Seattle subsidiary into a joint venture bid for the design of ground facilities for the *Minuteman.*

OPERATIONS ANALYST

You are invited to investigate unusual career opportunities with excellent futures in the science and engineering Laboratories of IBM. You will find this to be a unique opportunity to contribute original thinking to several important projects.

Our Laboratories are engaged in research and development of advanced electronic digital computers and control systems for the exotic-fueled B-70 strategic bomber, being designed to operate at altitudes of 70,000 feet and at speeds of more than 2,000 miles per hour. We have, in addition, projects in progress on future strategic air weapons, including global satellites, offensive bombardment space vehicles, and missiles.

Should have the ability to simulate tactics involving advanced weapons systems concepts, and derive methods for evaluation of operational effectiveness of alternate design concepts. An M.S. in Mathematics, or Physics with a thorough background in mathematics, and at least two years' experience in applying advanced mathematical techniques to weapons systems evaluation is desired. A knowledge of probability theory and linear programming techniques is also desired.

Salary commensurate with experience. Advancement based on merit. Employee benefits are among the best in industry today.

Please write, including resume, to:

Mr. R. L. Lang, Dept. 604G4

INTERNATIONAL BUSINESS MACHINES CORPORATION

contracts

ARPA

$4,046,119—**International Telephone & Telegraph Co.**, for ground-based communication stations for Project *Courier*.

$3,614,515—**Philco Corp.**, for Project *Courier* communications equipment.

$1,283,740—**Radiation, Inc.**, for Project *Courier* ground-based antennas.

NAVY

$23,500,000—**Pratt & Whitney Div. United Aircraft Corp.**, for continued work on the J-52 turbojet engine used in planes and missiles.

$4,500,000—**Northern Ordnance Inc.**, Minneapolis, for engineering and production of *Tartar* surface-to-air missile launching systems.

$2,400,000—**Beech Aircraft Corp.**, Wichita, Kan., for design, development, fabrication and production of a missile target system, including one prototype target.

$2,000,000—**Packard Bell Electronic Corp.**, for design and production of the ancillary test console subsystem, a portion of the *Polaris* automatic checkout and readiness equipment (subcontract from **Lockheed Missile and Space Div.**).

$300,000—**Arnoux Corp.**, Los Angeles, for design, fabrication and installation of telemetry data, receiving and recording station to be installed at Point Mugu.

$200,000—**Aeronutronic Systems, Inc.**, Glendale, Calif., for additional Pacific missile range instrumentation study.

AIR FORCE

$42,101,389—**Federal Electric Corp.**, Paramus, N.J., for operation and maintenance of the Distant Early Warning Line.

$1,706,469—**Convair Astronautics Div., General Dynamics Corp.**, San Diego, for installation of a new improved *Azusa Mark II* missile tracking system.

$794,200—**Lumen, Inc.**, Joliet, Ill., for miscellaneous projectors, instruction books and progress reports (missile support equipment).

$600,000—**Coleman Engineering Co., Inc.**, Torrance, Calif., for design and construction of missile ground handling equipment (two contracts, one for lift and transportation trailers and workstands for *Hound Dog* air-to-surface missile and the other for a missile nose cone transportation trailer for **Avco Corp.**).

$328,630—**Alabama Bridge & Iron Co.**, Talladega, Ala., for trailer and lift for aircraft and missile engines.

$192,500—**Food Machinery & Chemical Corp., Westvaco Chlor-Alkali Div., N.Y.**, for 110,000 lbs. of unsymmetrical dimethyl hydrazine for evaluation studies as a rocket fuel.

$158,743—**Recordak Corp.**, N.Y., for printer-process viewers, microfilm type (missile support equipment).

$107,640—**Consolidated Systems Corp.**, subsidiary of **Consolidated Electro-dynamics Corp.**, Monrovia, Calif., for high-speed digital data recording system.

$82,491—**Bell & Howell Co.**, Chicago, for 320 amplifiers with cover for use in 16 mm motion picture sound projectors (missile support equipment).

$80,284—**Leeds & Northrup Co.**, Philadelphia, for precision potentiometers and accessories (in addition to a previous award of $233,000.).

$43,430—**Pilotless Aircraft Div., Boeing Airplane Co.**, Seattle for technical data for *IM99A* missile components.

$29,911—**The Houston Fearless Corp.**, Los Angeles, for replacement parts for A-9 and A-11 processing machines (missile support equipment).

ARMY

$7,132,408—**Blaw-Knox Co., Power Piping Div.**, Pittsburgh, for *SM-65* iauncher facilities, Fairchild AFB, Spokane, Wash.

$1,900,000—**Martin Co.**, Orlando, for electronic equipment used in air defense coordination systems.

$1,891,532—**Western Electric Co., Inc.**, N.Y., for *Nike* spare parts and components (six contracts).

$1,447,333—**C. H. Leavell & Co.**, El Paso, Tex., for construction of guided missile maintenance shop at Pueblo Ordnance Dept., Pueblo, Colo.

$1,064,969—**Fred R. Comb Co.**, Minneapolis, for construction of SAC missile facilities located at Minot AFB.

$958,942—**Technical Construction Inc.**, Mobile, Ala., for phase II equipment for preflight evaluation laboratory at Redstone Arsenal.

$400,000—**Parabam, Inc.**, Hawthorne, Calif., for production of astrodome type shelters for the protection of missile tracking instruments.

$397,566—**Norris-Thermador Corp.**, Los Angeles, for T-238 rocket motor assembly.

$384,911—**Emerson Electric Co.**, St. Louis, for facilities for production equipment of *Little John* program.

$242,896—**Whaley Co., Inc.**, Birmingham, Ala., for construction of propellant development facilities at Redstone Arsenal, Huntsville.

$199,523—**Redding & Co., Inc.**, Baltimore, for construction of special AAA *Nike* missile field maintenance shop at Fort George C. Meade.

$188,037—**Emerson Electric Manufacturing Co.**, St. Louis, for pre-production engineering studies for rockets.

$141,245—**Orlando Welding & Piping Contractors of Orlando, Fla.**, for construction of guided missile liquid fuel facilities at Cape Canaveral Missile Test Annex, Patrick AFB.

$129,224—**Douglas Aircraft Co., Inc., Charlotte Ordnance Missile Plant**, Charlotte, N.C., for *Nike* spare parts and components.

$100,000—**The Siegler Corp.**, for the manufacture of special electronic test gear for the *Sergeant* missile (subcontract from **Sperry Utah Engineering Co.**, subsidiary of **Sperry-Rand Corp.**).

$99,650—**Atlantic Research Corp.**, Alexandria, Va., for solid-propellant rocket sustainer motor for automet test vehicle.

$93,428—**Western Electric Co., Inc.**, N.Y., for semiconductor diode devices.

$92,004—**Teletronics Laboratory, Inc.**, Westbury, L.I., N.Y., for various type oscilloscopes.

$65,000—**Bowmar Instrument Corp.**, Ft. Wayne, Ind., for the manufacture of a miniature servo-package to be used in the guidance system of the *Pershing* missile.

$54,502—**The Hickok Electrical Instrument Co.**, Cleveland, for signal generators.

$54,179—**Southwestern Industrial Electronics Co., Div. of Dresser Industries, Inc.**, Houston, for design of servo amplifiers for Redstone Arsenal.

$51,188—**Gilfillan Brothers, Inc.**, Los Angeles, for research work for twelve months to survey guided missile design practices including technical reports.

$49,435—**Ampex Corp.**, Los Angeles, for video tape recorder and head assemblies.

$39,873—**Midwest Research Institute**, Kansas City, Mo., for research and development on loading missiles due to atmospheric turbulence and wind shear.

$28,780—**National Research Associates, Inc.**, College Park, Md., for design, construction and demonstration of an operating mock-up of a minimum ground pressure vehicle.

$27,516—**Heiland Div., Minneapolis Honeywell Regulator Co.**, Denver, for six direct writing oscillographs.

NATO's Strength Backs West Berlin

While the ministers of the world's major powers debate the future of Berlin, a problem which is unavoidably bound to the future of all of Europe, General Lauris Norstad goes quietly and almost relentlessly about his job of strengthening the NATO forces which keep the Geneva meetings a debate and not an ultimatum.

The sword and the shield of NATO have become so legendary in the ten years of their existence that it now seems almost impossible to separate them from the national forces of the NATO nations. France, Britain and the United States are the Western occupying powers which guarantee the freedom of West Berlin. West Berlin, strictly speaking, is not part of NATO, even though West Germany is. Nevertheless, NATO is on record as supporting the position of the occupying powers and—while an attack on West Berlin nationals per se *would not* be an attack on NATO, an attack on any of the troops of the three Western powers in West Berlin *would be*. So, inevitably, NATO links itself to the freedom of West Berlin and publicly recognizes that encroachment there is no different than encroachment on any other free territory in Europe.

This fact rarely if ever comes out in the discussions which are held between the ministers of the East and the West, but it certainly cannot be far from the minds of Soviet leaders that in the Berlin situation Russia faces not just the three occupying powers but 15 allied nations and probably the greatest military force the Free World has ever seen in peacetime.

The sword forces of NATO are the great retaliatory forces—the big bombers of SAC and Britain's Bomber Command, plus the atomic Navy forces in the Atlantic. Just added—and NATO-committed—are the four squadrons of *Thor* intermediate range ballistic missiles now operational or becoming so in England, an addition of 60 atomic warheads aimed at 60 predetermined targets (see page 11). Joining them within a year or so will be two squadrons of *Jupiter* IRBM's stationed in Italy. And a little later two more *Jupiter* squadrons—one each in Greece and Turkey, most likely. These latter four will be under General Norstad's actual command as Supreme Allied Commander Europe and will comprise the first actual NATO atomic force. (Other nuclear forces, while supporting NATO, are under the command of their national leaders.)

The shield forces of NATO are 22 divisions of ground forces strung from Turkey in the south to Norway in the north, with the heavy concentration in the center. Many of these ground units are equipped with nuclear missiles and rockets, more are becoming so. They are supported, again from Turkey to Norway, by fighter planes many of which also carry atomic weapons.

The NATO goal for this shield force is 30 divisions; while not more important than the retaliatory forces, it certainly is no less. These 22 divisions, as one official expressed it, give NATO political and military flexibility. It is the force the people of the NATO countries can see and know about, watch flying overhead or wheeling through maneuvers. It is their visible protection against limited aggression. Like the sword force, its ability to react must be immediate and effective. And it is NATO doctrine that any unit should have a nuclear delivery capability if that is necessary to the unit's mission.

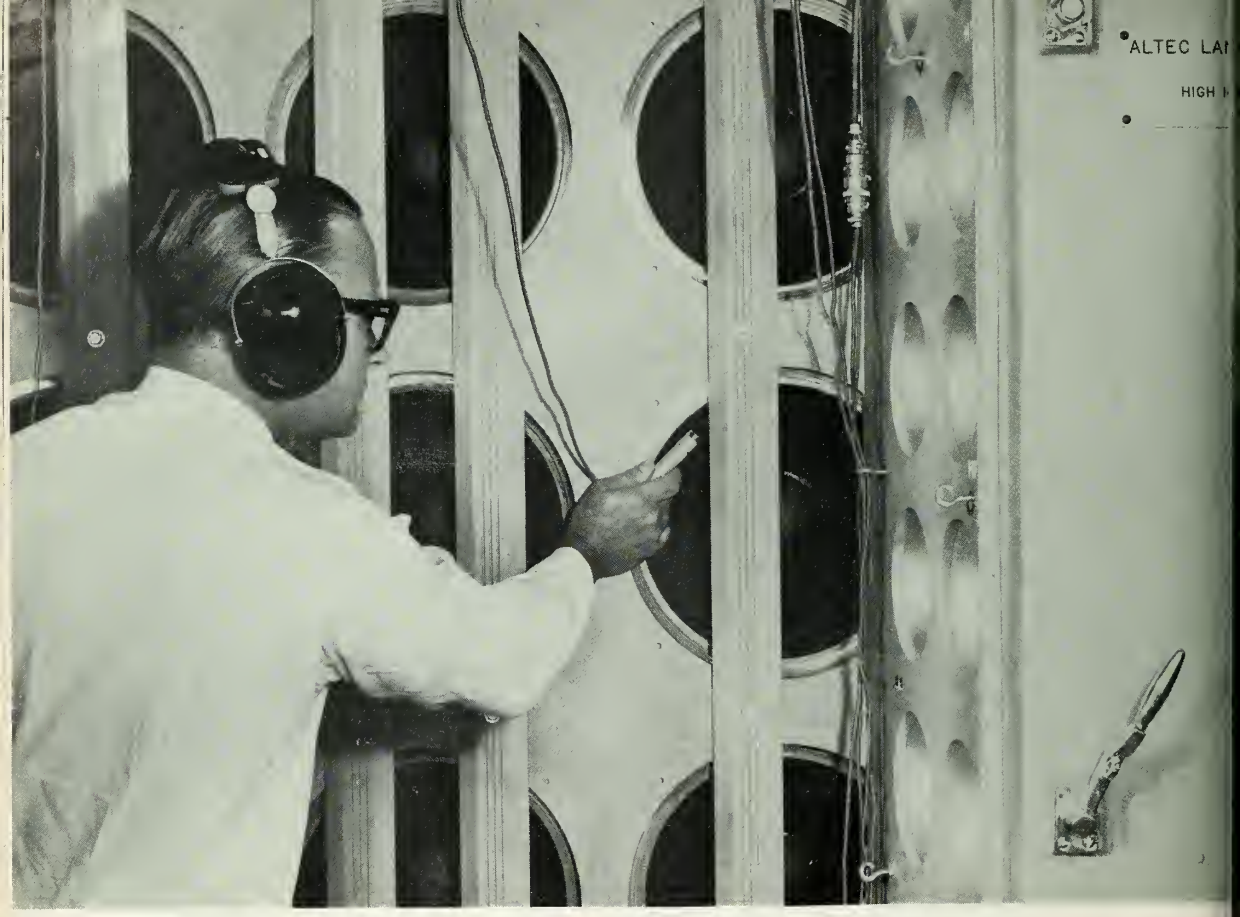
"This shield force of 22 divisions," the official said, "represents the difference between all or nothing—the difference between all-out war and knuckling under to Soviet demands otherwise."

The forces of the three Western Powers—France, Britain and the U.S.—in West Berlin are negligible, and it is the shield force of NATO which gives strength to the arguments of the Western Ministers in Geneva.

This shield force General Norstad continues to build up with inflexible will. A unit of the Italian army recently was equipped with the nuclear-armed *Honest John* rocket and has been trained by its U.S. allies to use it expertly. The Greek Air Force has been practicing for months in the delivery of atomic bombs by fighter planes and will be nuclear-equipped as soon as bi-country agreements can be worked out. Similar negotiations are underway with Turkey. New weapons supplant old as fast as they can be procured.

No one talks about NATO in the Berlin situation. It is just there, providing a great measure of the strength from which the ministers of the West maneuver.

Clarke Newlon



Avco and a Modern Minuteman—Recent work at Avco led to a solution of the missile re-entry problem, and to production of the nose cone for the Air Force Titan ICBM. Now the Air Force announces a development program for Minuteman, a solid fuel missile that will be capable of instantaneous firing with no preparatory fueling delays. Its nose cone, too, will come from Avco's Research and Advanced Development and Lycoming Divisions . . . implementing this modern Minuteman's vigilant defense of our shores.

UNUSUAL CAREER OPPORTUNITIES FOR QUALIFIED SCIENTISTS AND ENGINEERS . . . WRITE AVCO TODAY.

AVCO MAKES THINGS BETTER FOR AMERICA / AVCO CORPORATION / 750 THIRD AVENUE, NEW YORK 17, N. Y.

High Intensity Sound

a destructive, powerful force...a useful, versatile tool!

The destructive forces of high intensity sound – both in vibration and heat produced – are now better understood and better controlled through the use of testing chambers such as this latest Ling-Altec Reverberation Chamber.

Here, an Engineer adjusts one of the monitoring microphones in a chamber that can produce over 150 db of white noise – enough to equal the noise spectrum of the most powerful modern jet engines.

Even greater forces can be produced in Ling-Altec Plane Wave Tubes with air modulated devices which concentrate the power of high intensity sound many times.

These developments are a part of the continuing leadership of the Ling-Altec combination – high power electronics and high intensity sound!

DOW | MAGNESIUM PRODUCTS

ARE YOU GETTING ALL THESE BENEFITS WITH YOUR MAGNESIUM CASTINGS?

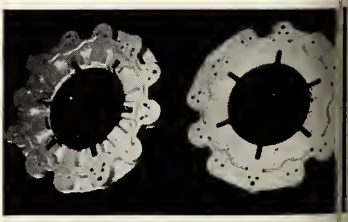
Dow magnesium foundry offers experience, production capacity for sand and permanent mold castings of all sizes and shapes.

The unique capabilities of Dow's Bay City, Michigan, foundry help users of magnesium sand and permanent mold castings. Activities at this facility—largest and best equipped of its kind—run the gamut from large volume production jobs to one-shot "specials".

Huge or tiny castings. The foundry is capable of producing castings weighing in excess of 3,000 lbs. down to ounces—in all degrees of complexity. Experienced pattern engineers ensure that the best use of casting processes is made. This can result in either lower costs, improved quality, better deliveries, or a combination of all three.

Newest techniques. Many milestones in magnesium casting have been reached at this Dow foundry. In fact, Bay City has men permanently assigned to developmental work, keeping the foundry in the forefront of technological advances at all times.

Results of their work include special processes for cast-in inserts and tubeless passages, and improved melting techniques. Casting methods have been developed for many of the newer magnesium alloys, such as the elevated temperature group and the new high damping capacity alloy, K1A.



Quality control. A full time quality control team exhaustively checks all work, from alloy composition to the shipping dock. A direct-reading spectrometer makes rapid alloy composition analyses. Its speed is particularly valuable when alloying elements that are hard to hold in the molten state, such as thorium, are present. Chemical analysis is also frequently employed.

Testing facilities. Molding and sand cores are analyzed as a regular part of casting quality control. Radiography, fluorescent penetrant inspection and other testing facilities are used to check properties and specifications.

Experienced magnesium team. The foundry often draws upon the broad range of specialized experience available throughout the company. To Bay City customers, this means assurance of high quality work, done with utmost efficiency and economy. If your requirements involve magnesium castings, Dow can help you arrive at optimum casting design and reliably supply your production requirements.

THIS SAND CAST WAVE GUIDE was held to ±.0 on passageway dimensions. Surface smoothness quirements are 63 RMS. The foundry has governn approval for any phases of its operations where approvals are applicable.

THIS BRAKE CARRIER is sectioned to show how hydraulic lines were integrated by use of tub passageway casting techniques.

WRITE TODAY for this illustrated brochure discussing Dow foundry services. THE DOW CHEMICAL COMPANY, Midland, Michigan, Magnesium Product Sales Dept. 1303CLB-3.

THE DOW CHEMICAL COMPANY • MIDLAND, MICHIGA

Washington Countdown

IN THE PENTAGON

A new type of guidance system . . . called *Fingerprint* is under consideration by the Air Force. **Chance Vought** is the developer. The system is proposed for use in *Slam*—the proposed supersonic low altitude missile that would be powered with a nuclear ramjet engine.

• • •

Project *Slam* . . . is still in the study stage. **Chance Vought, Convair** and **North American** are in the competition for the R&D contract. *Slam* apparently is being designed with the idea of getting past any Soviet-developed anti-missile missile.

• • •

Big new family of "pocket" missiles . . . designed for limited nuclear warfare can be expected to result from development of **Martin's** *Davy Crockett*. The secret Army missile with its fractional-yield nuclear warhead is designed to be fired like a rifle grenade. Next to be added to the new family of nuclear weapons probably will be **Martin's** *Bullpup*. (See page 12)

ON CAPITOL HILL

Deep slashes in the foreign aid bill . . . are worrying a number of defense-minded Democratic congressmen for political reasons. They fear the reductions in money slated to buy missiles for NATO undercut their fight for bigger defense expenditures at home.

• • •

Foes of a double congressional check-rein . . . on missile and aircraft procurement can be expected to try to kill it again next year. Meantime, it is certain to go on the law books with a 1962 effective date. The new provision will force the Pentagon to get congressional authorization of missile and aircraft procurement programs prior to getting Congress to vote the cash.

AT NASA

The proposed imperfect orbit . . . of the "paddle wheel satellite" *Thor Able III*, scheduled for launching Aug. 7 has been modified from an apogee of 30,000 miles and a perigee of 150 miles to an apogee of 20,000 miles with the same perigee. Reason: Though NASA scientists would like to test the multi-solar celled payload at the longer distance, the shorter apogee is designed to give the *Thor-Able* vehicle a better chance of performing the mission.

• • •

A competitor for *Thor-Delta* . . . the small satellite booster under development, is reported being proposed by ABMA and JPL. NASA recently cut *Juno II* and *Thor-Able* from its programs in favor of *Thor-Delta* on grounds they are uneconomical. ABMA now is proposing as a substitute a *Jupiter*-JPL 6K combination. The 6K is a second stage with an encapsulated, storable 6000 pound thrust engine.

• • •

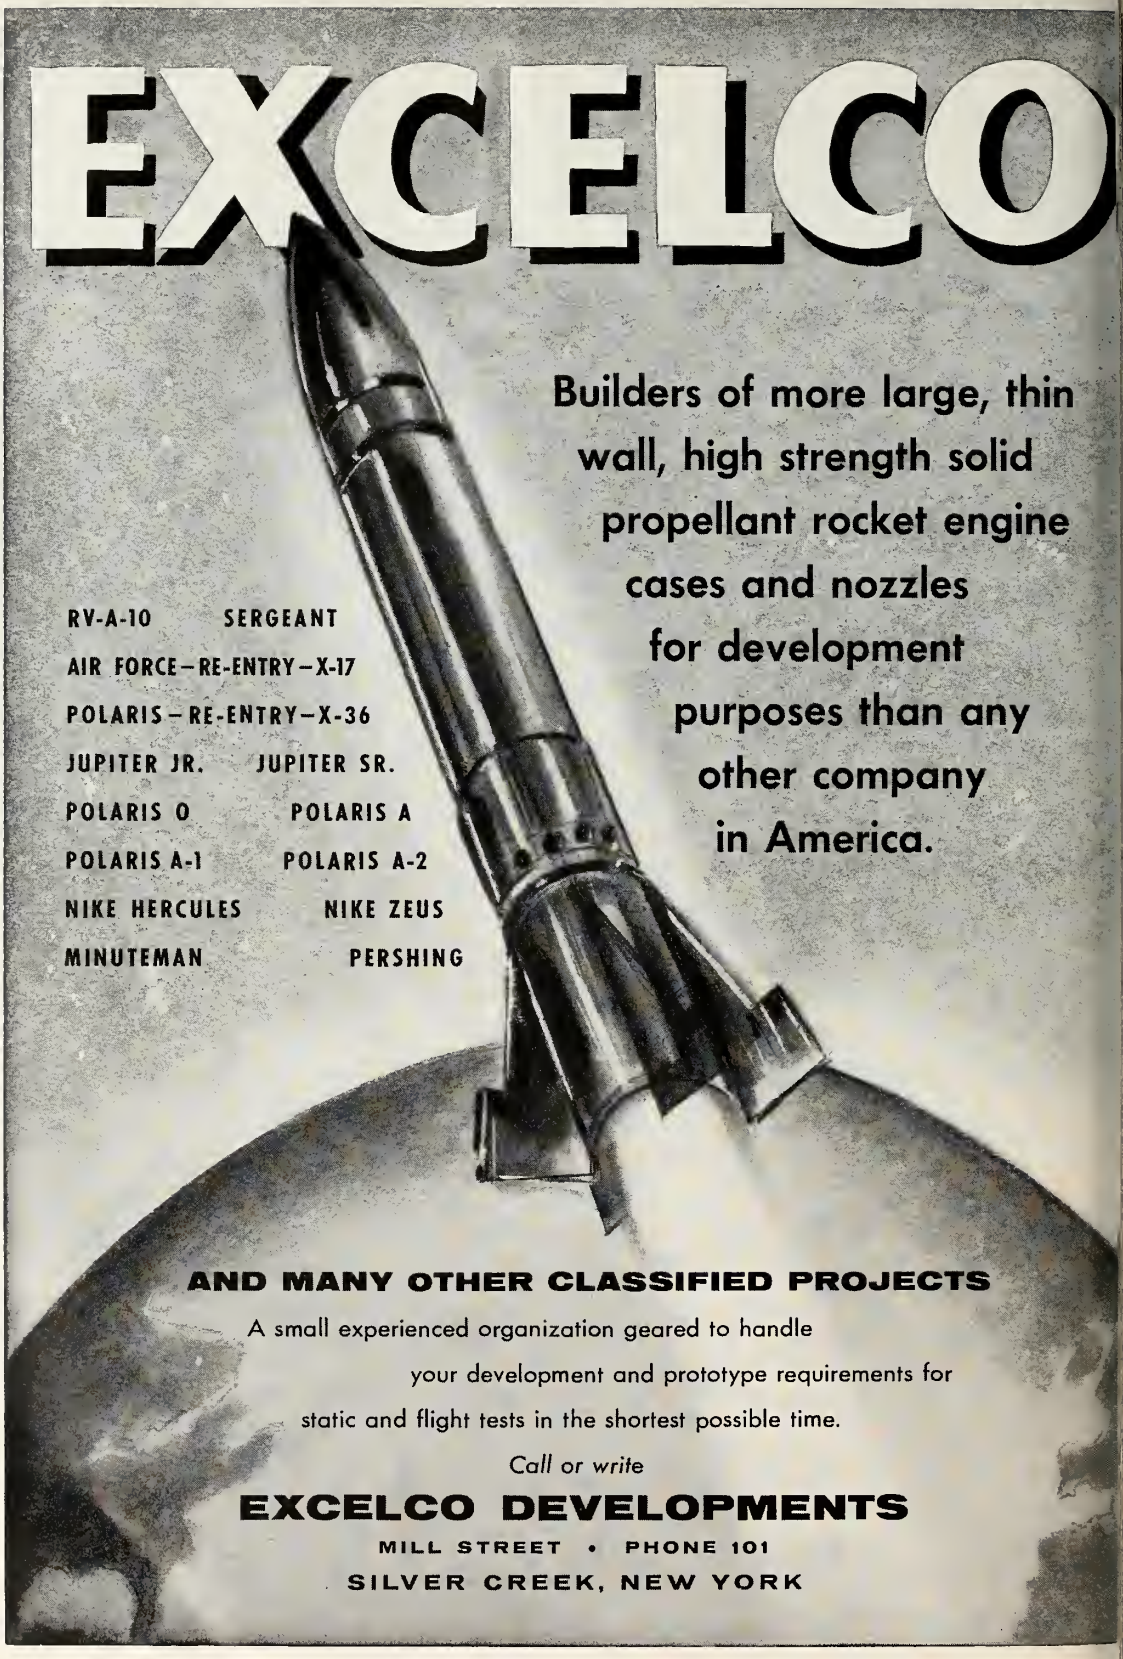
Launching date censorship . . . of NASA space projects has put the space agency in the embarrassing position of having to deny what they know to be true. For example, English newsmen learned from NASA technicians at Jodrell Bank that *Thor-Able III* was to be launched June 7 and transferred this information to their American colleagues. NASA is under pressure from the White House and Cape Canaveral's Maj. Gen. Donald Yates not to release satellite launching dates before the fact.

AROUND TOWN

More large Soviet missile bases . . . are reported to be under construction in the Eastern European satellites. Iron Curtain sources report the Russians are closing off large tracts of land for the bases. The amount of heavy construction indicates that hardened sites are being built.

• • •

The Kremlin apparently decided . . . in advance of Vice President Nixon's Soviet tour that it might be a good idea to let him see a missile launching. A top Soviet source says Nixon's chances of seeing one looked good . . . all he had to do was ask.



Some of the reports . . . that are being passed as the "latest" in the nation's capital:

. . . The Administration is determined to hold the budget line next year for the presidential campaign. It looks now as if only a major international flareup can change the decision.

. . . The U.S. radar net in Turkey has detected more than 30 Soviet failures to launch either ICBM's or space vehicles.

. . . Red China is putting new pressure on the Soviet Union for red missiles.

Industry Countdown

STRUCTURES

Combat *Atlas* ICBMs . . .

are now in the hands of 704th Strategic Missile Wing missile troops at Vandenberg AFB. While Air Force is still ironing out bugs which showed up during recent test failures, these **Convair**-made missiles are considered "ready to shoot" in event of war. All changes resulting from tests are being programmed immediately into these missiles. Unit will not be declared operational until after the 6300-mile *Atlas* passes four or five more flight tests.

• • •

Proposals are descending . . .

on NASA at rate of 60 per month. About 250 have been submitted since January—two-thirds of them from universities and remainder from industry. Average proposal would cost $102,000. They range from such basic research projects as the physics of certain structures under stress to the R&D of instruments to be used for a space vehicle landing on another planet. NASA officials report that they are funding about 34% of the proposals at an average of $62,000 each. Their big problem: money. "We have more good proposals than we know what to do with," says one expert. "We can't afford to sponsor them all." Funding of proposals from universities comes from special $3 million account, while industry proposals are paid for out of R&D money.

• • •

The French will activate . . .

first *Nike* and *Honest John* missile battalions this autumn . . . Britain's **Bristol Aeroplane Co.** is running a feasibility study of Mach 7 commercial transport that would take off pick-a-back style with a separable booster weighing 250,000 pounds. Plane would be powered by both turbo-jets and rockets.

Hebert Has Hand Grenades Ready To Toss

by James Baar

WASHINGTON—So far the House Armed Services Subcommittee investigation of the so-called "munitions lobby" has taken on the aura of a relatively pleasant tennis match.

However, Subcommittee Chairman F. Edward Hébert (D-La.) can be expected shortly to try serving up a few hand grenades.

The subcommittee has spent most of the month since it opened its investigation listening to testimony from other congressmen, top military officials and retired high-ranking military officers now holding key jobs in the defense industry.

Both the unsensational conduct of the hearings and some superficial reports have given the impression in a number of quarters that the whole investigation is preparing to wander off somewhere and die.

This impression is very misleading. Actually the subcommittee has proceeded according to pre-established plans.

The subcommittee has sought to hear first from the number of prominent figures whose names were tossed about in the noisy developments that brought on the hearings. The second phase is scheduled to involve detailed examination of specific cases.

• **Testimony may be damaging**—Moreover, the testimony taken to date could well be far more damaging than it may at first appear.

One by one the witnesses beginning with Deputy Defense Secretary Thomas Gates have sat in the crowded subcommittee room and stated that they know of no attempts by retired military officers to influence defense contract awards by the Pentagon.

As Gates told the subcommittee: "All these contracts are made in the interest of the department and are not awarded on any other basis—friendship, influence or anything else."

Gen. C. S. Irvine, former Air Force Deputy Chief of Staff for Material and now an **Avco** vice president, testified bluntly: "If I wanted to make sure my company didn't get a contract, I would go talk to my successor and ask him to do me a special favor."

But under questioning most witnesses also said other things.

For example, Irvine agreed that he might be more readily listened to by a former junior officer who over the years had come to respect his judgment.

Others agreed that it certainly might be easier for a retired military officer to gain the ear of a former associate still in the Pentagon.

And Gates, himself, said that the president of a company was its "No. 1 salesman" and agreed that the company's board chairman was its "No. 2."

The new Deputy Secretary attempted at this point to draw a distinction as to what is meant by the term "salesman."

"What is selling?" he asked rhetorically.

"That is what we are trying to find out," Hébert snapped.

Since then subcommittee members have repeatedly quoted Gates as in identifying defense contractors' "No. 1" and "No. 2" salesmen.

• **Not enough testimony**—In all, the subcommittee already has enough of such testimony to state in its report if it chooses that a number of the nation's top present and former military leaders concede that the subtle pressuring of military officers by their former military associates is possible.

What is still lacking, of course, any proof that this is what has be happening.

That is what the subcommitt staff is already digging for as it si more than 5,000 questionnaires ma out by ex-military officers and e Federal officials now employed by c fense contractors. That—or the lack it—is what will make up the seco phase of the hearings.

The subcommittee can be expect to attempt to show that the award Contract X was influenced by alleg influence brought to bear by retir Gen. or Adm. or Col. or Cmdr. Y.

Nor for the purposes of bringi about new legislation need such e dence be capable of standing up in court of law. It needs only to be stro enough to convince Congress and t public.

The writing of any legislation th might result from the hearings wou be an extremely complex problem. many astute lawmakers have found the past, it is most difficult to legisla honesty.

However, several proposals have ready come up a number of times the hearings.

One would put some kind of b —say two years—on the hiring of r tired military officers for anything b technical jobs. Of course, such a li is most difficult to draw.

A second proposal is that Pent gon officers involved in the contra ing process be required to submit li of all who talk to them about contrac to all interested parties.

Other proposals are far mc drastic.

Whether any of them will ever enacted into law will depend on hc explosive Chairman Hébert's ha grenades may prove to be.

QUOTABLE QUOTES ON RETIRED OFFICERS

General of the Army Omar Bradley, now chairman of the board of the **Bulova Watch Co.**—*"The greatest contribution we can make is because of our experience in administration and organization."*

Rep. Paul J. Kilday (D-Texas), high-ranking member of the House Armed Services Committee—*"I take the position that no officer should retire and soon thereafter enter the employment of a contractor in a position which would give him an opportunity to have that contractor favored or even give the appearance of so doing."*

Vice Adm. Hyman Rickover—*"I believe it is where you get up to captain and admiral and it is in positions such as Washington representative or where due to their personal contacts (they) can influence policy."*

Rep. Samuel Stratton (D-N.Y.)—*"It would be a grave mistake if this committee were to proceed in the assumption that there is something inherently wrong with a retired c ficer going to work for a defense contractor . . ."*

Rep. Alfred E. Santangelo (D-N.Y.)—*". . . I sense odorous aura created by the extensive hiring of retir military personnel. This practice . . . smells to the hi heavens and races with missiles and aircraft to outer space*

Gen. C. S. Irvine, (ret.), now vice president of Av Manufacturing Corp.—*"You just can't go back and say a guy who used to work for you: 'You know, give me a ha sandwich.' You got to have a little pride."*

Rep. Porter Hardy Jr. (D-Va.), Hébert Subcommitt member—*"No military man or nobody else . . . would into the office of a procurement officer and say: 'Do me favor and buy what I have here.' I don't think it would done that way. But there are a lot of other ways to sk a cat."*

TWO YEARS of development time shaved off *Titan*.

BMD's 'Radical Approach' To ICBM Pays Off

Concepts of concurrency & central-direction responsibility produce ahead-of-time weapon systems

by Erica Karr

WASHINGTON—Five years ago this ıth Brig. Gen. Bernard A. Schriever ı over command of ARDC's new ıtern Development Division, set up accelerate the Air Force's ICBM gram. In a short half-decade the anization, which became the Air ce Ballistic Missile Division, ıched and proved out a revolution- approach to development of a pon system. Using the concept of currency (simultaneous develop- ıt of components), and turning over responsibility for engineering and nnical direction to the **Ramo-Wool- lge Corp.**, the AF ICBM program lved ahead of schedule, with an mated two-year shaved off develop- ıt of the *Atlas, Titan* and *Thor*.

Growing at first slowly from a ıp of less than 50, Gen. Schriever's entific community" expanded to to- 's 1600, backed up by the 3000 em- ed of **Space Technology Labora- es** (offshoot of Ramo-Wooldridge). In the long record of achievements, e highlights stand out:

• Re-entry—Bucking general scien- opinion, BMD proved through its es of tests with the *X-17* ballistic vehicle that successful re-entry was ible at more than 12 times the d of sound (July, 1956).

• *Thor*—First fully successful flight of the *Thor* 105 (September, 1957).

• *Atlas—Atlas* takes off without a hitch for the first time. (December, 1957).

• Capsule Recovery—Data from space was recovered with the capsule sent up at 10,000 mph in a *Thor* re-entry vehicle (June, 1958).

• ICBM flight—The first successful ballistic flight, impacting successfully after re-entry at ICBM range was achieved after second launch of a *Thor Able* (July, 1958).

• *Pioneer*—Deepest probe into space by a man-made object was *Pioneer I's* 71,300 mile journey during which it picked up data confirming existence of the Van Allen radiation belts and confirming they would not be insurmountable obstacles for man in space (October, 1958).

• Full-range *Atlas—Atlas* capability was confirmed when it flew 6300 miles (November, 1958).

• Operational *Thor*—First SAC launch of operational-type *Thor* took place three years after it was given ok for development (December, 1958).

• Multi-stage ICBM — Completely successful first test flight of the *Titan* launched the free world's second type ICBM—a multi-stage heavier and "more sophisticated" vehicle.

JOB OF BMD now is preparing for operational status of Atlas ICBM. Here is t concept of proposed facility at Warren AFB, Wyoming.

"FOUNDING" father of BMD was Brig. Gen. Bernard A. Shriever, now heading ARDC.

• Polar-launched satellite—*Discoverer I*, man's first polar-orbiting satellite circled the earth over 10 days. Weight with orbiting 2nd stage—1300 pounds (February, 1959).

• Re-entry vehicle recovery—*Thor Able* carried aloft a test vehicle which radioed back evidence of its successful re-entry and then was retrieved from the Atlantic Ocean where it impacted (April, 1959).

• Space Pix—First pictures of on-the-scene rocket separation were made by motion picture camera carried by *Thor IRBM* re-entry vehicle to 300 miles altitude (May, 1959).

Looking to the future, BMD has set for itself an ambitious long-range goal: development of integrated space forces, since "space is our newest military medium." Meanwhile, BMD's sights in the near future are set on perfection of the missiles now in being; bringing to maturity such second generation missiles as the *Minuteman*, concentrating on greater mobility and protection at launch and greater accuracy; development of a reconnaisance satellite, a satellite-launched missile, and an anti-missile defense system satellite (MIDAS).

Convair *Redeye* is fired from tube.

REDEYE AND BULLPUP

Bazooka-type missile details released
Martin ASM becomes operational in Atlant

by James Baar

WASHINGTON—The Army and Navy have publicly unveiled two of their latest missiles—the **Convair** *Redeye* and the **Martin** *Bullpup*.

One carries death over the battlefield to straffing jets. The other carries death to ground installations and ships at sea.

Development of both arises directly from needs learned in battle.

Army foot soldiers have needed a light, mobile weapon to strike back at ever faster tactical aircraft. So have the Marines. They will get *Redeye*.

Navy pilots have needed a substitute for costly divebombing. So has the Air Force. They will get *Bullpup*.

Both missiles pack conventional warheads. However, the Navy is understood to be planning development of a *Bullpup* with a nuclear warhead.

The Navy also is planning development of a super Bullpup with a conventional warhead. This would pack the punch of a 1000-pound bomb. The present model contains a 250-pound bomb.

The Army unveiled its formerly-secret *Redeye* for the 1959 annual meeting of the Association of the U.S. Army.

• **Redeye specs**—The four-foot long, solid missile is designed to be fired by one or two men from a tube similar to the bazooka. Its diameter is about three inches. It has infra-red guidance and undoubtedly has a proximity fuse. The entire weapon weighs about 20 pounds —some 15 pounds lighter than a bazooka of approximately the same size.

The *Redeye* program—now in an advanced R & D stage—was started before the Korean War. More than 5 million has been spent on it.

The missile is one of the first o a series of new secret missiles being veloped for arming an Atomic Army. Among the others are *Claym* and the Martin *Davy Crockett*.

Davy Crockett, a nuclear-tip missile designed to be fired like a grenade, is of particular interest in development of a nuclear *Bullpup*. generally similar fractional yield head would be used for both missi

The Navy demonstrated the ca bilities of the newly-operational *B pup* as part of a fire power show on the end of July from the Car Saratoga.

The carrier, which lay about miles off the Florida coast, launc three Douglas A4D Skyhawks arm with one *Bullpup* each. The th

FOUR FOOT long *Redeye* **has a diameter of about three inches and carries infra-red guidance.**

ENTIRE WEAPON weighs about 20 pounds, some 15 po lighter than a bazooka and probably carries a proximity f

HESE A4D's can carry three *Bullpups* if extra fuel is not required. Aircraft belong to VA-34 of CAG-3, NAS Cecil Field, Fla.

hter-bombers fired their missiles at oke pot targets floating on a rela-ely calm sea. One missile overshot target. Two scored direct hits.

The Mach 1.8 *Bullpup* is 11 feet g. It has a one foot diameter. It ighs about 600 pounds including a 0-pound conventional warhead.

The simply-designed missile is di-ed into three sections: The rear sec-n contains a solid motor and tracking res; the center, the warhead; the se, the command guidance and con-l equipment.

The *Bullpup* can be launched at a get from 12,000 to 15,000 feet away. e launching plane then follows the ssile part of the way in while the ot guides it with a thumb switch. e launching plane is able to pull out its dive while it is still one to two es from the target.

The missile is designed to meet two cific problems:

• Cut the high loss of aircraft ced to fly through heavy ground fire.

• Improve the reduced accuracy of nbs dropped by supersonic aircraft.

• **Deployed in Pacific**—Operational *llpups* were deployed for the first e aboard the Carrier Lexington in Pacific.

An A4D can carry three *Bullpups* t does not carry extra fuel tanks. **North American** FJ Fury can carry .

So far Navy pilots generally have nd *Bullpup* a highly reliable and urate missile. However, the principal blem confronting them at this time btaining enough for training. Most *llpups* now being manufactured are ed in the national war stockpiles.

The Air Force originally sought de-opment of a much more advanced ion of *Bullpup* known as *White Lance*. This plan now appears to be dead. Instead, the Air Force will buy a *Bullpup* with a few special modifications.

At present, the *Bullpup,* because of its relatively small warhead, is designed for use against such targets as bridges, tanks, pillboxes and similar ground installations.

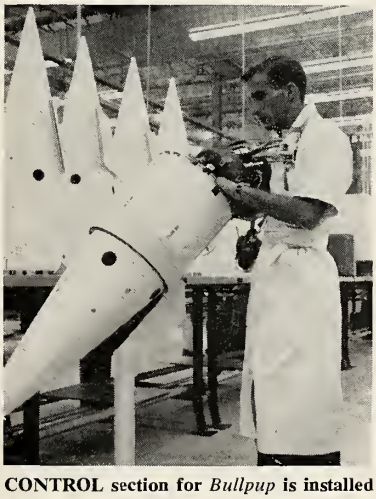
However, the nuclear-loaded *Bullpup* would be capable of sinking any ship afloat. The Air Force also would presumably be interested in such a weapon for tactical use.

A *Bullpup* with a nuclear warhead would not need the great accuracy of the conventional models. It could be fired from greater distances and the launching plane would not have to follow it as far toward a target.

The peak destructive overpressure from a shallow underwater nuclear explosion carries much farther than it does in an air burst.

For example, only an 8 kiloton warhead detonated nearly a half-mile from an enemy ship would smash its hull with an overpressure of about 3000 pounds psi.

An overpressure of 3000 to 4000 pounds psi is considered sufficient to sink any ship of substantial construction. But even much lower overpressures can sink a ship or completely disable it. And overpressures of less than 1000 are considered sufficient to badly damage internal equipment.



Finally, such underwater blasts even a considerable distance from a ship also result in damage to superstructures from both shock waves in the air and high waves.

• **Development of weapons**—Like *Bullpup, Redeye* and *Davy Crockett* are part of an overall attempt by both the Army and Navy to build up the nations limited war potential.

Such weapons are designed to enable a small force to mount sizeable firepower against an attack by much larger conventional forces.

Some observers have noted a trend in congressional thinking toward a greater buildup of such forces in the next few years. However, without a budget increase the billions that would be needed for such a buildup would have to come from funds that have been spent in the past for a buildup of U.S. strategic forces.

Moreover, there has been no indication that the cost of maintaining U.S. strategic power is about to decrease. Instead, with the coming of hardened missile sites and large-scale ICBM production, it is expected to increase.

CONTROL section for *Bullpup* is installed at Martin's Orlando, Fla. facility.

ARPA Obligating $18 Million for Solids Research

by Betty Oswald

WASHINGTON—The Advanced Research Projects Agency is spending a total of about $33 million for exploration in new high-energy solid propellants and supporting programs. Of this figure $18 million will be obligated in fiscal 1960.

The objective is to develop improved solid propellants with useful energy 10 to 20% above the solid propellants now being used. The net effect would be to double the warhead-carrying capacity potential of future intercontinental ballistic missiles.

Funding in 1959 amounted to $15 million spread over 54 contracts in seven broad research areas. As listed in a Pentagon Fact Sheet, they are:

• **Integrated programs:** $6,000,000—4 contracts. **Minnesota Mining and Manufacturing; American Cyanamid; Dow Chemical; Esso Research & Engineering.**

The integrated program concept involves thermochemistry, thermodynamics and performance estimates; chemical studies aimed at the synthesis of new ingredients; propellant formulation and compounding; and the study of the properties of the final propellant including ballistic and mechanical properties all in a single contract. The primary criterion for the selection of these contractors was the caliber and suitability of the scientific personnel available. The concept involves the definition of the research program in terms of the objective rather than in terms of ways and means of attaining the objective.

• **Propellant performance:** $1,720,000—11 contracts. National Bureau of Standards; University of California; Ohio State; **Arthur D. Little;** Bureau of Mines (Bartlesville); **Allegany Ballistics Laboratory; Aeronutronic Systems, Inc.; Rohm & Haas; Atlantic Research Corporation;** University of Chicago; University of Wisconsin.

A substantial program has been set up involving the selection and assembly of best thermodynamic values, performance calculations based upon these values, and kinetic studies aimed at the elucidation of processes which occur during expansion. These studies are providing a firm basis for the selection of those areas of chemistry which are most likely to contribute substantially to the desired goals.

• **Specialized synthesis:** $3,840,000—18 contracts. **Magna Products;** Penn State; Duke University; New York University; University of Florida; WADC, Materials Laboratory; Rohm & Haas; NOTS, NOL (Corona); **Olin-Mathieson; Allied Chemical; Callery Chemical; Monsanto Chemical; Pennsalt; Borden; Peninsular Chemresearch; Ethyl Corporation;** Atlantic Research Corporation; **National Research Corporation.**

The work under the integrated programs involves a large percentage of synthetic work. However, the necessity for new ingredients, if the objectives are to be achieved, recommends the placement of contracts concerned solely with synthetic work. This type of program will enable the DOD to obtain the services of laboratories especially highly qualified in certain branches of synthetic chemistry of special pertinence. The principal areas covered in the specialized contracts for synthesis already placed or planned include: new oxidizers, new light metal fuels, and research directed towards new chemical techniques.

• **Propellant research:** $750,000—3 contracts.

The new ingredients which are expected to become available as a result of the synthesis programs are likely to have properties quite different from those now used. This would recommend that new compounds be made available as quickly as possible to all major propellant research centers. However, it is also essential to preserve the Government's interest by seeing that compositions involving new ingredients do not become proprietary if the research is Government-sponsored. It has been decided that initial work on the use of new ingredients would be confined to certain laboratories which are free of proprietary restrictions. The designated laboratories are:

Ordnance Missile Laboratory; Naval Ordnance Test Station; Picatinny Arsenal; Naval Propellant Plant; Jet Propulsion Laboratory; Rohm and Haas, Redstone Division.

All propellant research on new ingredients coming out of ARPA synthesis contracts will be coordinated through the three Services.

• **High temperature research:** $900,000—8 contracts. Applied Phys Laboratory; Allegany Ballistics Labo tory; **Union Carbide Corporation; C nell Aeronautical Laboratory; Aton International; AVCO Manufacturi General Electric;** National Bureau Standards.

Present day high performance s propellants have flame temperatures the vicinity of 5000°F. Propella now under development may be s stantially hotter and accordingly, s ject the inert parts to extreme cor tions. It is necessary to have a resea program designed to solve this proble The research program planned invol the mechanism of ablation, proper of refractories, insulation studies, a a study of the pyrolysis of orga polymers. These programs are meant supply fundamental knowledge as the resistance of inert components high temperature.

• **Non-destructive testing:** This p gram is now being reviewed and de sions will be announced shortly. Due the fact that solid-fuel engines are coming successively larger every ye this has placed an ever increasing mand on the mechanical properties the propellant. Failures such as cra ing, separation from the liner and ar of porosity are likely to occur. Th faults can increase the burning surfa over that expected, leading to predictable and occasionally disaster pressure increases. Additionally, c tain faults may expose the wall surfa of the engine to high temperatures p maturely, leading to failures at oper ing pressures. Accordingly, an advanc solid propellant program should clude a substantial effort on techniq for non-destructive testing and insp tion. Failure criteria need to be veloped and instrumental methods the detection of faults require a gr deal of refinement. This program being reviewed for future funding.

• **Basic research:** $873,000—contracts. Bureau of Mines (Pittsburg Brooklyn Polytech; University of C fornia; Princeton University; **Aeroj General Corporation; Aerochemi Research Laboratory;** University Texas; **Stanford Research Institu Materials Research Corporation;** V derbilt University.

A variety of basic research progra involving many areas pertinent to t overall objective were set up throu the basic scientific offices of the th Services. These programs include study of detonation, the study of bu ing rate of solid propellants, meta able systems, ductile ceramics, ceran fiber-alloys, and various spectrosco studies of combustion products.

TV Watches Engine Case Tests

Newbrook Engine Corp. engineers learn how failure occurs by observing hydrostatic skin tests from safe vantage point

by Jay Holmes

SILVER CREEK, N.Y.—Closed-cir-uit television has been put to work sting rocket engine cases safely at a issile hardware plant here.

Engineers at the **Newbrook Ma-ine Corp.** have installed a TV camera side their hydrostatic test cell so ey can see just when, where, and what pressure a case begins to fail.

Newbrook, which manufactures ses for such large missiles as *Polaris*, *inuteman*, *Sergeant* and *Jupiter*, can st all of them in its cell. In most ses, observation by television makes possible to turn off the pressure be-re complete failure occurs. The otential failure is located precisely a small stream of water issuing om the spot. And the Newbrook en-neers know exactly how much pres-re causes the rupture.

Most hydrostatic testing of rockets is done in a closed chamber for safety. But without a TV viewer, cases are often tested to failure. And when they do fail, there sometimes is no way of knowing just where and when it happened.

Normally, the cases are tested for one minute at pressures up to 1235 pounds per square inch. However, additional pumps are available for pushing the pressure up to 10,000 psi.

The hydrostatic test is only one of several tests given rocket engine cases before they leave the Newbrook plant in this Lake Erie community. Hardness of the surface is checked with use of an instrument that measures magnetic and electric properties. This avoids damaging of the case in a diamond-point test. Other tests include tensile pulls, X-ray examination, bi-axial disc tests and hydrostatic tests of triaxial forces.

ELEVISION HELPS watch remote-control rocket-case test at Newbrook Machine.

A. J. Newman, Newbrook president, is confident that any metal can be welded to meet the exacting standards of the missile industry. As evidence, he showed a recent visitor dozens of cases tested to failure. In every case, the failure occurred away from the seam. "You have to do your welding properly," he said. "Close control is necessary. And you have to have welders who know their business."

Newbrook Machine is the second corporation started by Newman and Leroy Brooks, two engineers who set out on their own after World War II from the **Cornell Aeronautical Laboratory** in nearby Buffalo. They established **Excelco Developments Inc.** in 1946 and Newbrook in 1951.

They started small but have grown steadily. Employment now ranges from 200 to 250. Newbrook and Excelco say they have delivered more rocket engine cases for research and development than any other single vendor in the country to date.

Newbrook uses closed-circuit television for other uses besides watching what goes on in the test cell. A camera has been installed next to one bench where fine-tolerance machining is done. The worker can examine his piece of metal on an enlarged image in a television receiver above his head.

Another application is in maintaining plant security while showing customers the progress of their work. Often, work is being done on classified projects next to a civilian or unclassified job. In such a case, the customer may not be cleared to view the classified work. The solution is to point the camera at the unclassified job. Then the customer can view it on the office receiver.

Newbrook's facilities are sufficient for manufacturing the largest rocket cases that could be transported on a highway under a bridge. If he gets orders to build anything larger, Newman said, he will clear an area a half-mile away on the Lake Erie shore and fabricate at dockside.

No Action Soon on Industrial Security

Three bills introduced in Congress but vote not expected before next session even in light of Supreme Court decision

WASHINGTON—It's becoming increasingly apparent that industry will have to play the "industrial security program" by ear until the next session of Congress. This means that defense contractors will have to continue to follow the elaborate set of rules established by the Defense Department which are applicable both to military and National Aeronautics and Space Administration contractors.

Trouble will come only in those cases where a charge is made that an employee constitutes a security risk. A discharge of such an employee, even if ordered by the Pentagon, could cause trouble in view of the decision of the U.S. Supreme Court in the Greene case. There the high court held that the industrial security program was invalid since it was based neither on legislation nor an executive order of the Congress.

Seemingly this meant that the program could be revalidated by the simple act of issuing an executive order. However, there is language in the opinion of Chief Justice Warren which points to a new concern that those charged with being security risks must be given the right to confront their accusers. This language runs squarely counter to the basic security tenet that it is essential that informers and information gathered in so-called "raw" files be protected. Efforts to solve this problem have not been successful, and both the White House and the Justice Department continue "to study" the possible solutions.

• **Bills offered**—In the meantime, three bills have been introduced. Two (S2392, S2146) have been referred to the Senate Judiciary Committee but have not yet been assigned to a subcommittee for hearings. On the House side, one bill has been introduced. It's HR8121, introduced by Rep. Francis E. Walter (D-Pa), head of the House Un-American Activities Committee.

That Committee has asked for reports from the affected executive departments but has not yet received replies. Until those replies are received, hearings are not considered likely.

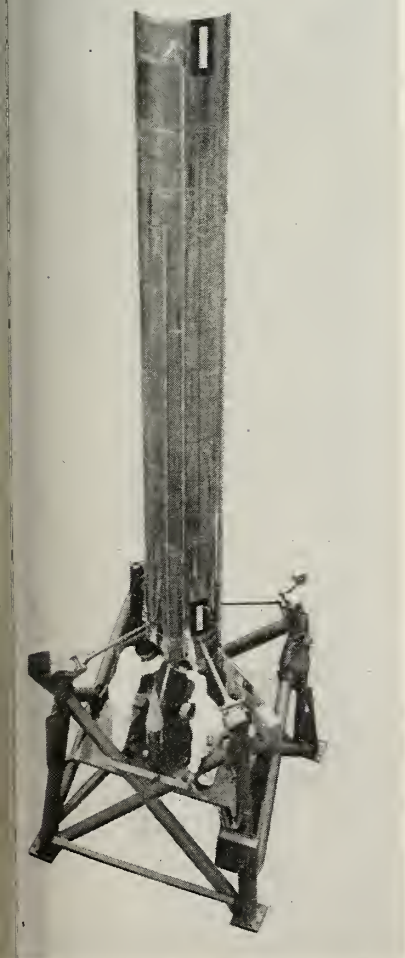
On the Senate side, one bill, S2392, has been labelled as "emergency" legislation by its sponsors, Senators Olin D. Johnston (D-S.C.) and James O. Eastland (D-Miss.). It would establish legal authority for the industrial security program as required by the Supreme Court decision. It would not, however, touch the tricky constitutional question of the right of the accused to confront his accusers. In introducing the bill, Sen. Johnston commented that industrial security could thus be kept alive while Congress sought to determine what, if anything, should be done to solve constitutional questions.

The other Senate Bill, S2146, seeks to meet the right of confrontation head-on. Introduced by Senators Thomas J. Dodd (D-Conn.) and Kenneth Keating (R-N.Y.), the bill, in the words of its sponsors, is designed "to eliminate unsupported charges by faceless informers in such cases by subjecting them to confrontation and cross-examination, and at the same time to protect regularly established confidential informants engaged in intelligence work for the government whose identity may not be disclosed without compromising the national security."

Under the terms of the Dodd-Keating bill, any person denied clearance for access to classified information or material or whose clearance has been suspended shall be given: (1) a written statement within 30 days showing the reasons, "stated as specifically and in detail as security considerations permit"; (2) an opportunity within 30 days to reply and submit affidavits in support of such reply; (3) a hearing, at his request, before a hearing officer designated for such purpose, who is required to prepare a recommended decision; (4) a review of the recommended decision by the head of the agency involved; and (5) a written statement of the decision of the agency head.

The bill spells out in detail how hearings shall be conducted to pro maximum opportunity for the acc to protect himself. It provides am other things that hearings shall be c ducted so as to assure "a full disclos of any evidence against the acc and confrontation of all adverse nesses."

• **Exception**—There is one imp ant exception spelled out. This w bar the right of the accused if a fin is made by the hearing officer agency head that the national secu public safety or public interest w be adversely affected. However, bill would bar reliance on "deroga information" as a basis for den clearance "unless the applicant has furnished a statement by the hea officer summarizing such informa in as much detail as is possible wit adversely affecting the national secu safety or public interest."



The bill also assures the right person who loses security clearance his job, as a result, to recover the ference between the pay he would earned if allowed to remain on the and his aggregate earnings during period in which his employment suspended or terminated. Obviou this right goes only to the man wins his case on review.

• **No action soon**—Despite fact that this bill comes close to m ing the goals set by the Supreme Co it is a virtual certainty that Cong sional action will be delayed until next session at the earliest. Infor sources say that lack of time a would dictate the delay. They add there is no particular urgency at time since defense contractors are erally playing along, and can alw pass on the bill to the Pentagon discharged employee successfully a fight for reinstatement.

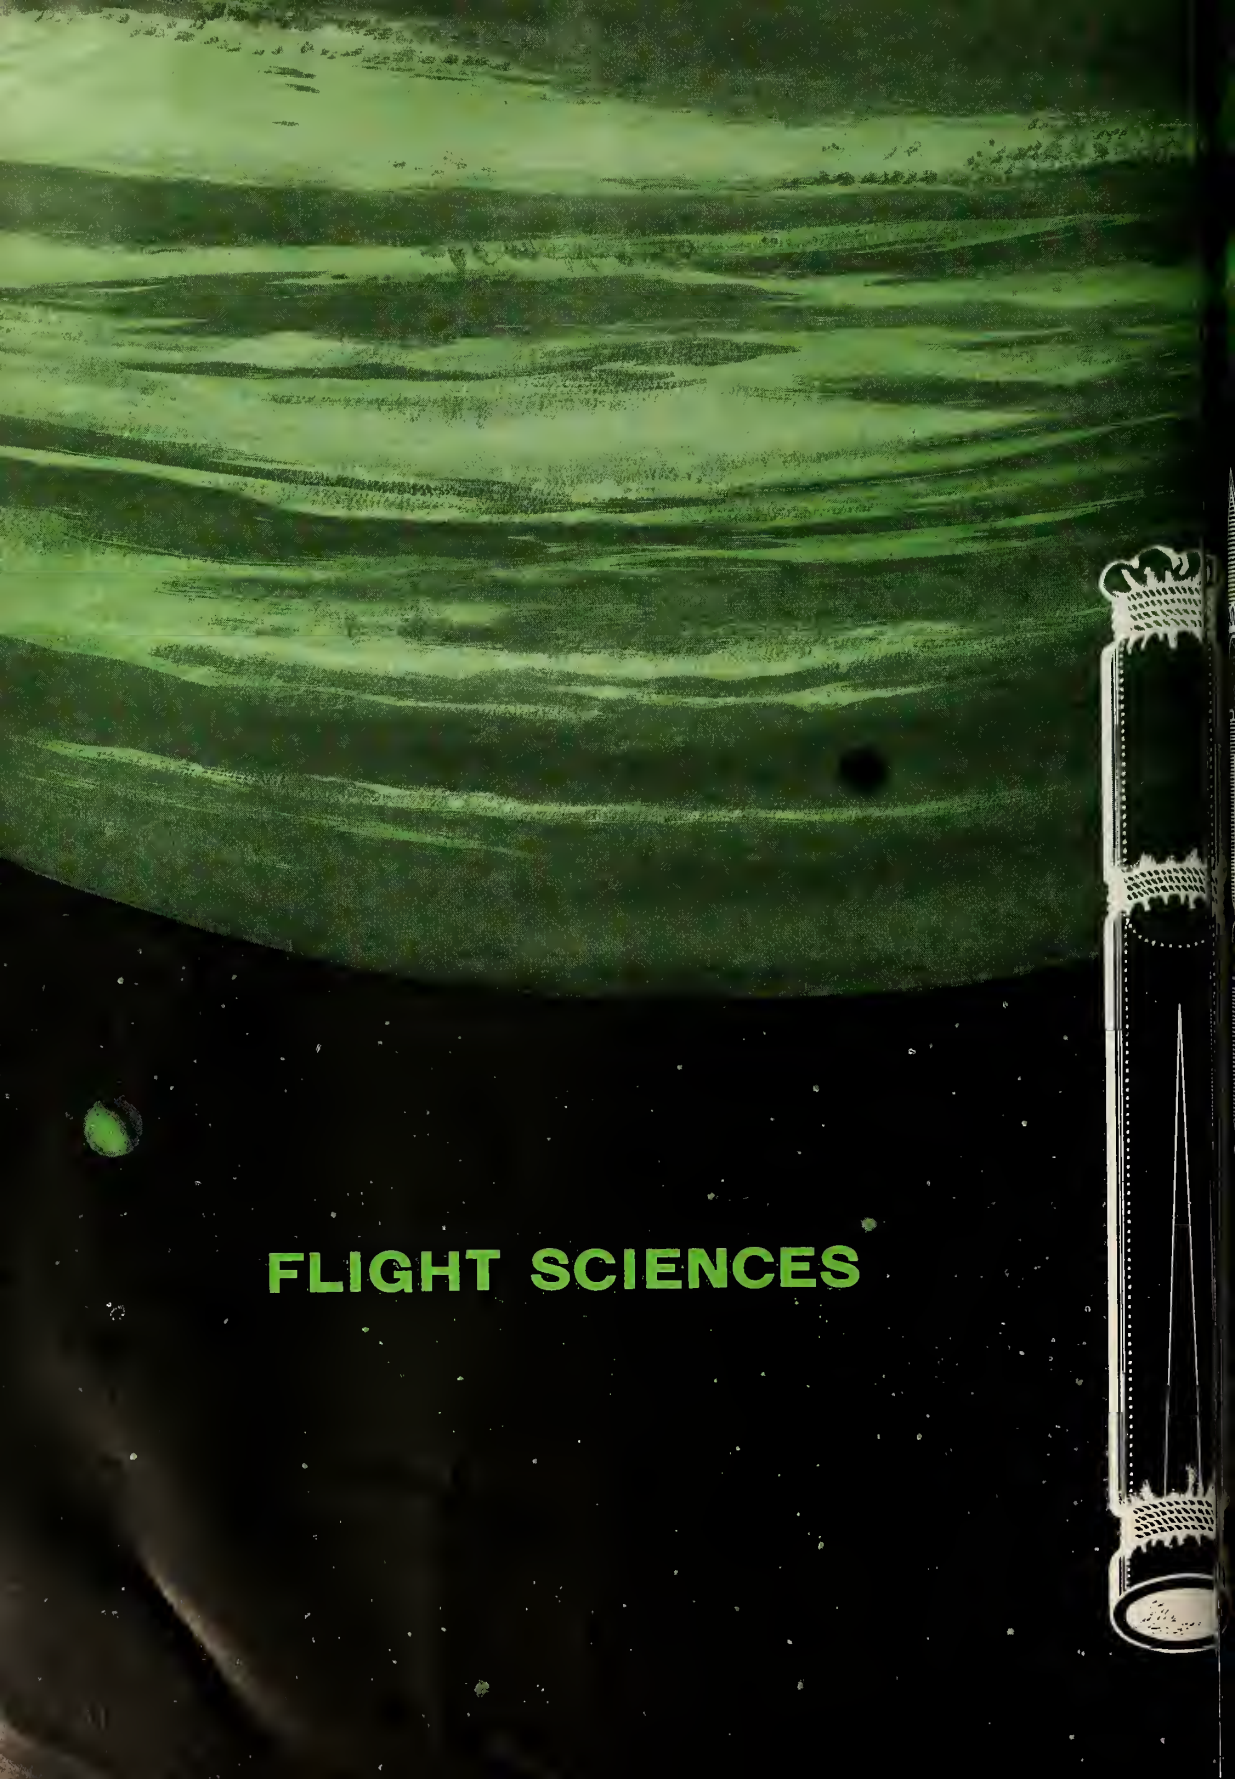
Other tough problems include need for a definition of such term "derogatory" information, as well clear definition of the procedures u which adverse security decisions w be reviewed.

RESEARCH

BRISTOL SIDDELEY GAMMA ROCKET ENGINE POWER BLACK KNIGHT-BRITAINS HIGHLY SUCCESSFUL SPACE RESEARCH VEHICLE

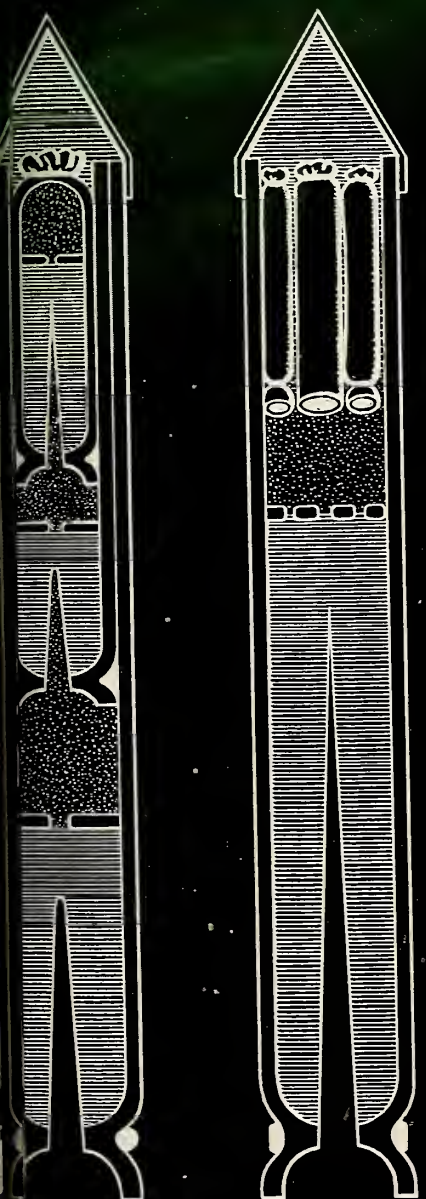
On the 11th June, 19,000 lb. of thrust sent Black Knight to the threshold of outer space—500 miles above the Woomera rocket range in Australia.

This was the third successful firing *(there have been no failures)* and much of the credit for Black Knight's trouble-free performance must be given to the Gamma.



The Bristol Siddeley Gamma 201 is a liquid propellant rocket engine. Four trunnion-mounted chambers burn kerosene with HTP and each chamber is fed by its own turbopump unit. The complete weight of the engine compartment is less than 700 lb. (dry) and Gamma delivers 19,000 lb. at altitude—16,400 lb. at sea level.

Black Knight is a research vehicle and no military applications are planned. But the experience gained and lessons learned from this highly successful space probe will be invaluable in the development of Britain's IRBM—Blue Streak.



So impressive is Black Knight's performance with the Gamma powerplant that even more advanced applications are being actively developed. In fact, Black Knight coupled with Blue Streak is first choice to put Britain's projected space satellite into orbit.

FLIGHT SCIENCES

FLIGHT SCIENCES: Principle of the step or multi-stage rocket, considered fundamental to the art of modern missiles and space flight, was set forth as long ago as 1650 by Kazimierz Siemienowicz, lieutenant-general of ordnance to the king of Poland. His design featured a 3-stage rocket with each step having its own gunpowder fuel, fuse, and nozzle.

EXPANDING THE FRONTIERS OF SPACE TECHNOLOGY

Pioneering work at Lockheed is being conducted in free molecular flow in orbital flight; high altitude atmospheric properties; trajectory studies and missile flight dynamics; celestial mechanics with emphasis on orbital tracking predictions and de-orbiting.

Lockheed's capabilities in gas dynamics and thermodynamics are unsurpassed in private industry. Basic work is being performed in boundary layer flow and heat transfer; cooling and insulation; thermodynamic flight test; instrumentation; rocket motor controls and nozzle structures; reentry and materials; thin film thermometry; and measurements of dissociation and re-combination reactions.

Fundamental studies include hypersonic aerodynamics; environmental effects on satellite surfaces; magnetohydrodynamics; ultra-violet and infrared radiation from high temperature air flows; structure of hypersonic shock waves; new measurement methods; analysis of boundary layers near melting surfaces and study of lag or non-equilibrium in high speed flow through shock waves.

Equipment includes an electrically-driven wind tunnel—fastest in industry—which produces airflows to Mach 20-plus and stagnant temperatures approaching 16,000°F, with an instantaneous power output of 20 million kilowatts. A spark-heated, magnetically driven research shock tube produces velocities of over Mach 250 and temperatures of 500,000°F, and a specially designed, electric gun has accelerated projectiles to speeds approaching 20,000 ft/sec.

Major emphasis in structures concerns the design of reentry bodies, thrust termination and underwater launching devices. The Navy Polaris FBM required the solution of complex structural problems necessitated by the unique launching environment—water.

Other significant work has been accomplished in diversified aspects of aerodynamic and hydrodynamic load distribution, aeroelastic effects, studies of special dynamic problems arising from aerodynamic disturbances, cavitation, launching conditions and thermal problems relating to analysis of a complex structure taken through a complete time-temperature environment.

Lockheed Missiles and Space Division programs reach far into the future and deal with unknown environments. It is a rewarding future which scientists and engineers of outstanding talent and inquiring mind are invited to share. Write: Research and Development Staff, Dept. H-29, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship required.

Centaur Engine Tests Begin

Scheduling calls for Pratt & Whitney to deliver first operational liquid hydrogen engine to Convair in 1960 for use in NASA's space vehicle Centaur, to be finished in 1961.

by Paul Means

WASHINGTON—The nation's first second generation space engine—**Pratt & Whitney**'s liquid hydrogen-liquid oxygen XLR 115 P-1—is scheduled for delivery to **Convair Astronautics** for integration into NASA's *Centaur* space vehicle in 1960.

Two years later, the high energy engine will be placed on top of ABMA-ARPA's million and a half pound thrust clustered *Saturn* booster for initial flight tests.

XLR 115 P-1, which will give the upper stage push to perform such missions as orbiting 24-hour communication satellites and sending man to the moon and back, is currently undergoing full scale developmental static run-up tests at Pratt & Whitney's Florida Research and Developmental Center at Palm Beach, Fla.

THRUST CHAMBER of XLR 115 is lifted onto test stand for static firing.

Its first use will be as the second stage of *Centaur,* which will have the Convair *Atlas* for its first stage, and optional use of JPL's 6 K, a 6,000 pound thrust storable propellant engine, for its third stage.

Upon receipt of the Pratt & Whitney engine, Convair has about one year, under present scheduling, to design and fabricate the second stage, and to integrate and test the complete *Centaur* vehicle before delivery to NASA.

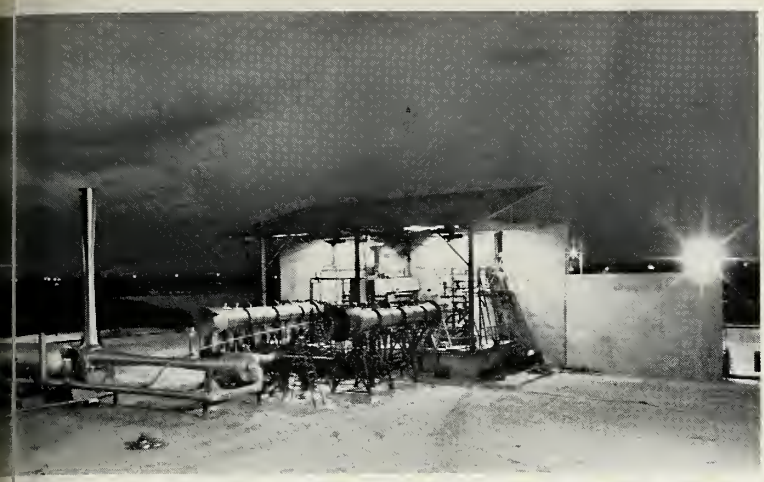
• **Six vehicles slated**—The six *Centaur* vehicles NASA has contracted for are staged to come through in intervals of about two months during 1961 and 1962.

Project *Centaur* was funded for $22 million by ARPA in FY 1959 and for $42 million by NASA in FY 1960. Estimated individual cost of the first six *Centaur* vehicles is $7,500,000.

Early development of liquid hydrogen as a rocket fuel has been carried on for some years by NASA's Lewis Laboratories at Cleveland, and by the Air Force.

The low molecular weight fuel has a heating value of some 2.8 times that of kerosene. Its specific impulse when used with liquid oxygen is 391 compared to 300 for a LOX-kerosene combination, an improvement of about 40%. In spite of its low density and attendant large tank volumes, liquid hydrogen's better fuel economy allows for great increases in payload weights.

Before liquid hydrogen could considered seriously as a space vehi fuel, methods had to be devised whe by it could be produced with exacti standards of purity in great quanti and could be handled and transport safely.



The U.S. Air Force, project sup visor of *Centaur* under ARPA, a retained in this role by NASA, beg large tonnage production of high pur hydrogen under contract to **Air Pro ucts Inc.,** at the U.S. Air Force Pla No. 74 in the Florida Everglades, r far from Pratt & Whitney's West Pa Beach facility. Other hydrogen pla initiated by the Air Force are an A Products, Inc. plant at Painesville, O and a **Stearns-Roger Manufacturing C** plant at Bakersfield, Calif.

AF Plant No. 74 combines cru oil, air and water to generate the g and then uses expansion turbines remove energy and liquefy it.

The liquefied gas is then shipp in Dewar tanks enveloped in nitrog to users. At the Pratt & Whitney W Palm Beach installation, the Air For currently is piping the fuel over distance of nearly half a mile in vacuum-jacketed pipe system.

The problems Pratt & Whitney fa in developing the first practical liqu hydrogen engine center around t fact that the cyrogenic material has boiling point of –422F°.

• **Quick disconnect necessary**—Since the Pratt & Whitney engine w be fired after the *Atlas* booster h carried it far into space, the fuel w have to be kept cold during the bas booster phase or the pressure in t tanks will rise to bursting point. Oth problems besides insulation inclu the necessity of keeping lines a

WILIGHT VIEW of Pratt & Whitney's double test stand for liquid hydrogen ocket engines showing the big tubes through which the engines fire.

PRATT & WHITNEY technicians prepare for an XLR 115 engine test.

umps from freezing, and the necessity making quick disconnects.

To counteract these problems, the ratt & Whitney test facilities simulate e space conditions under which the ngine will be fired by the use of yogenic plumbing, high-pressure gas rge systems, and a whole new techology of test instrumentation.

Rather than develop one 30,000 ound thrust engine for *Centaur*, P&W ngineers found it advantageous to uster two gimballed 15,000 lb. thrust ngines.

The XLR 115 P-1's components, nd full scale developmental models

HRUST CHAMBERS for *Centaur* ngine take shape in Pratt & Whitney's ssembly area.

are currently being tested on four large horizontal test stands constructed without government subsidy by Pratt & Whitney. The stands are designed to test engines up to 300,000 pounds of thrust.

A fifth and larger vertical test stand, jointly financed by the government and Pratt & Whitney, will have a capability of static testing a complete space vehicle, including engines and propellant tanks. This stand will be ready this fall—in time to begin the vertical testing of XLR 115-P-1.

The P&W engine will have a start-restart capability in flight, with sets of hydrogen peroxide rockets providing upper-stage altitude control during the coast period. The coast period, plus the high energy propellant, give the P&W engine a gain in payload weight of approximately 50% over *Vega* for similar missions.

Straightforward engineering progress should increase the thrust of XLR 115 in the near future from 15,000 lbs. of thrust to 20,000 lbs. of thrust.

• **Three more families**—Beyond the *Centaur* engine, P&W engineers are planning three families of upper stage liquid hydrogen eingines, one ranging from 10,000 to 30,000 lbs. of thrust, one from 30,000 to 100,000 lbs. of thrust, and one from 100,000 to 300,000 lbs. of thrust.

NASA has already indicated that engines from both the second and third families may be used on top of the 6 million pound clustered booster *Nova*.

And P&W engineers feel that progress in hydrogen engines will come with such rapidity that *Nova's* second and third stage hydrogen engines may be completed before the mammoth clustered booster is ready for them.

Though a liquid hydrogen-liquid fluorine rocket engine would be the ultimate chemical rocket engine, P&W engineers do not believe that the highly toxic oxidizer will ever replace liquid oxygen in liquid hydrogen engines.

They point out that liquid hydrogen's impulse is only slightly higher with fluorine than with oxygen, and there would be few missions which would require exploiting this advantage. On the other hand, hazards introduced by fluorine toxic and corrosive qualities should prevent its use as a propellant for manned missions.

DuPont Constructing Metals Research Plant

WILMINGTON, DEL.—**DuPont** will build a center for development research in niobium, niobium alloys and titanium at its Baltimore plant.

The installation, to be completed by the fall of 1960, will contain equipment to forge, extrude, roll, draw and heat treat all the refractory metals—such as tantalum, zirconium, tungsten and chromium. But it will concentrate on niobium and titanium at first.

F. H. Weismuller, general manager of DuPont's Pigment's Department, said basic research on other refractories will continue "while we engage in large-scale testing . . . of metals that are closer to commercialization."

The unit will be at a plant where DuPont has manufactured titanium dioxide white pigment for 28 years. The company has been interested in niobium, since known as columbium, since 1957, when it entered a joint development program with **Thompson Ramo Wooldridge Inc.** of Cleveland.

Inert-Gas Brazing Room Proposed

Aerospace Industries suggests manufacturers study joint establishment of 'space room' for high-temperature work on metals

LOS ANGELES—An industry group suggests it may be feasible to set up a jointly sponsored "space room" capable of providing a total inert-gas environment for welding and brazing metals.

The **Aerospace Industries Assn. of America** advanced the idea last week in its 1959 annual forecast of trends and requirements. The association proposed a study of the project's feasibility.

The report made no estimate of the cost. However, one engineer familiar with the association's thinking said such a facility could easily cost 10 or 15 million dollars. The engineer, who preferred to remain anonymous, said the idea is for a room on the order 40′ x 50′ x 6′ in size, where metals could be worked at temperatures up to 3500°F. The room would be used for both manufacturing and research.

Another idea being kicked around, the engineer added, is that equipment in the room should be entirely remotely controlled. This would have the obvious advantage that it would not be necessary to keep atmospheric temperatures down to those tolerable to human workers. Otherwise, they would have to be equipped with asbestos clothing and air helmets. The air in the room would be argon or some other inert gas.

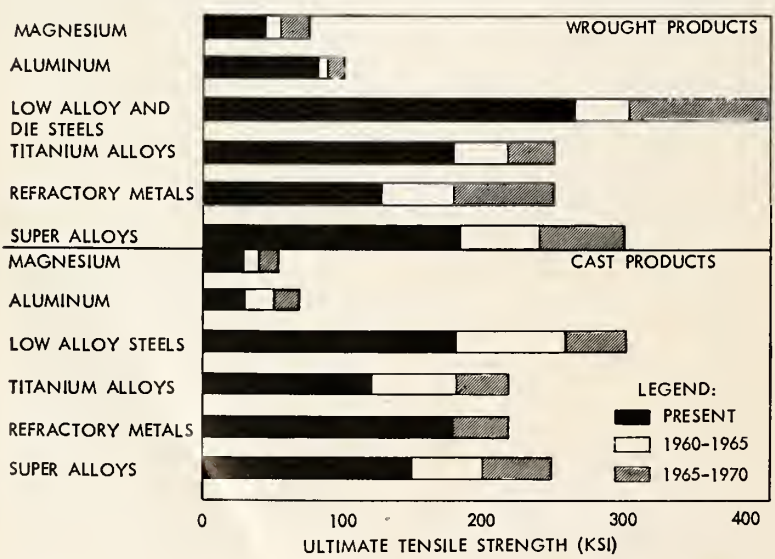
No consideration has been given to how the cost might be apportioned. It may not be possible to finance it without government sponsorship, the engineer said. As yet, however, no approach has been made to any government agency.

The industry group's report also forecast requirements within five years for missile materials that will withstand brief exposures to temperatures of 3000°F and within 10 years to 5000°F.

In addition to these stern demands, Aerospace Industries called for development of new materials and methods in ever-shorter time spans. The report outlined the needs of the coming decade in assembly and joining, metal shaping, materials removal, plating and cladding, and heat treatment.

• **Combined processes**—Trends in assembly and joining are toward brazed and welded structures and indicate particular need for equipment development in this area, the report said. Combined processes will be necessary—for instance, welding and machining in a welding positioner.

The two chief problems will be achieving the very close tolerances required and brazing, welding and heat treating in a controlled atmosphere. To produce a stress-free, dimensionally accurate unit and locate details throu high-temperature processes, precisi sub-assembly tooling will be needed. A sembly tooling and manufacturing w be required for joining large sub-asse blies already in the hardened con tion. For welding and localized he treating during final assembly, portab equipment and techniques must be d veloped.

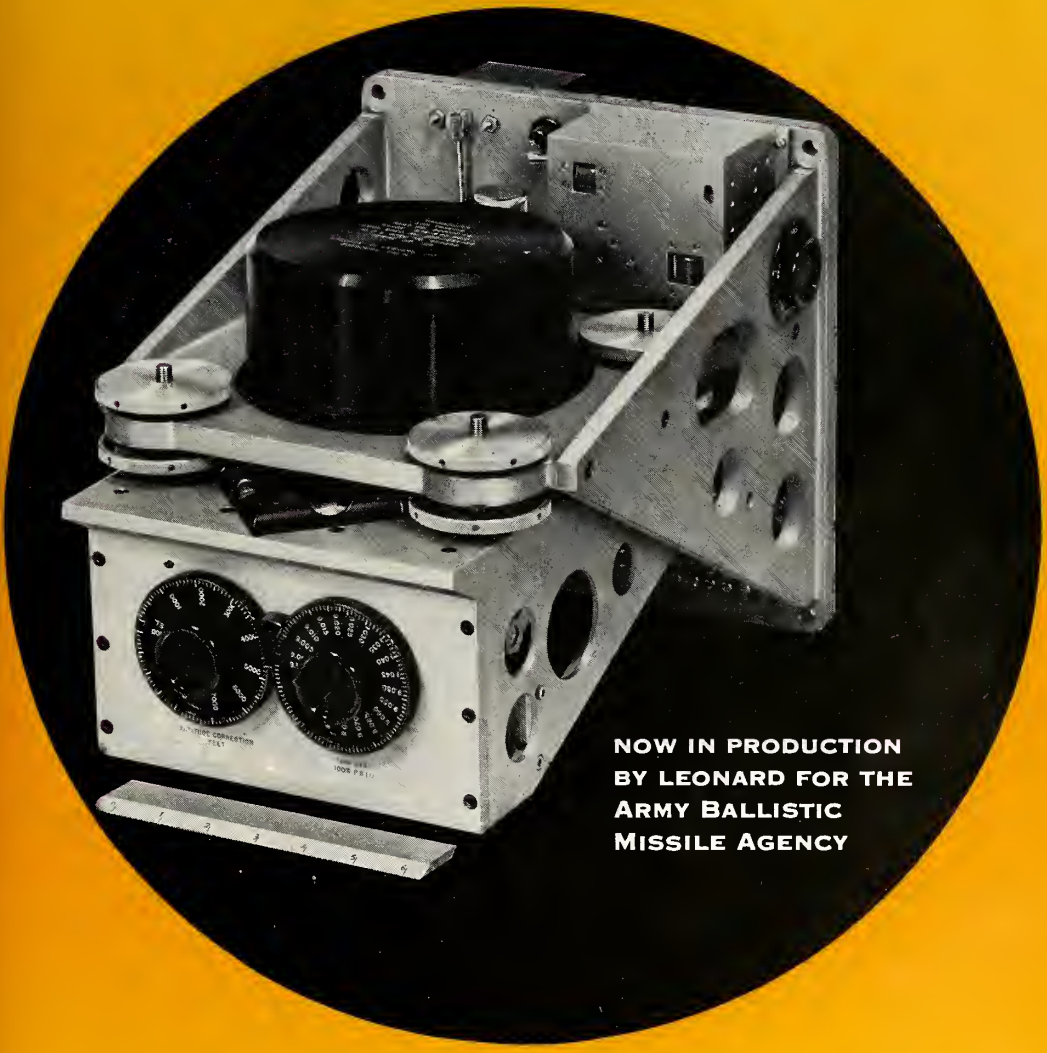


Aerospace Industries forecast ne for a method of joining metals witho heat. The group suggested an approa by use of metallic compounds plac in the joints, with fastening accor plished by a chemical reaction trigger by gas.

In metal shaping, the associatio predicted a demand for fabricatio techniques and equipment that w place the metal as close as possible its final configuration. This will con as more emphasis is placed on develo ing high-strength steels with yields 300,000 psi and titanium alloys wit yields of 200,000 psi.

• **Temperature barrier**—In materia removal, Aerospace Industries predicte that operations such as shearing, blan ing and machining, now performed room temperature, will have to be don with materials or tools heated or at sub zero temperatures. Since some meta and almost all ceramics and cerme cannot be machined with ordinar tools, these jobs will require cerami tools, ultrasonic machining or electric discharge machining.

Trends in plating and cladding in dicate the demand for automatic sys tems to control the processes, the asso ciation declared. The report called fo development of nondetrimental platin and cladding processes to withstan temperatures of 1200°F.



The industry association forecas demands in heat treatment for mini mum-mass materials for tempering an fixtures to control parts at treatin temperatures. Equipment for annealin or heat treating large component above 2000°F also will be required Sources using radiant heating or induc tion coils may be needed for treatin "localized" areas of assemblies to large for furnace treatment. The re port suggested resistance heating migh solve this problem.

ANTICIPATED increase in mechanical properties of wrought and cast alloys.

NEW LOX TANKING COMPUTER SYSTEM

WITH 1/10% OVERALL ACCURACY

NOW IN PRODUCTION BY LEONARD FOR THE ARMY BALLISTIC MISSILE AGENCY

OTHER RECENT CONTROL PROJECTS BY LEONARD INCLUDE:

What Can Withstand Re-entry Heat?

Bell Aircraft engineers find coated molybdenum, dense silicon carbide and coated graphite best for leading edge of boost-glide plane such as Dyna-Soar

LOS ANGELES—Coated molybdenum alloy, dense silicon carbide, and coated graphite are the most promising materials for the leading edge of the wings of a hypersonic global boost-glide plane such as *Dyna-Soar*.

Two **Bell Aircraft Corp.** engineers made this report at the recent national summer meeting of the Institute of the Aeronautical Sciences. The engineers, Frank M. Anthony and Harry A. Pearl, did not mention *Dyna-Soar* by name in their paper, "Selection of Materials for Hypersonic Leading Edge Applications." But their reference to a manned plane with range of 22,000 miles made it clear they were discussing that project.

In a "typical trajectory," they declared, such a craft would reach a peak altitude of 300,000 feet six minutes after launch, at which time the vehicle velocity is 25,400 fps and a range of 700 nautical miles has been traveled. During the ensuing descent, when vehicle weight is balanced by lift plus centrifugal force, a range of 21,900 miles is traveled in 105 minutes.

The end of the glide is assumed to come when altitude falls to 85,000 feet and velocity drops to 1200 fps. From this stage on, the flight is considered to be in the landing phase.

Dynamic pressures and temperatures each peak twice during such a flight, once during boost and once during descent.

• **Critical conditions**—These data show that three potentially critical flight conditions exist—high dynamic pressure combined with moderate temperature during boost, high temperature combined with low dynamic pressure during glide, and high dynamic pressure combined with low temperature during landing. However, Anthony and Pearl report, studies have shown that air load stresses are not a major consideration in selecting hypersonic leading edge materials. The real problem is high temperature.

In the typical *Dyna-Soar* flight, the Bell engineers estimate that maximum temperatures will range from 2600° to 2900°F, when the benefits of geometry and material characteristics are considered.

They screened materials for oxidation resistance, thermal conductivi thermal expansion, thermal emissivi tensile strength (metals) and modul of rupture (non-metals).

Molybdenum and its alloys w given a favorable report because high thermal conductivity, low coe cient of thermal expansion, high mod lus of elasticity and high mechani strength at elevated temperatures. T metal oxidizes rapidly, however, temperatures above about 1200°F form a corrosive oxide that is volat at about 1500°F. Some alloys poss higher mechanical strength and high crystallization temperatures but truly oxidation-resistant alloy has be developed.

Anthony and Pearl reported th an 0.5% titanium, 0.07% zirconiu alloy developed this year is appreciat stronger than other alloys and has recrystallization temperature of abo 2900°F—the upper limit of the te perature range for a *Dyna-Soar* lea ing edge. The short-time ultimate te sile strength of this alloy is 54,000 at 2400°F and 14,000 psi at 3000°F

• **Silicon coating**—A good coati

TABLE I COMPARISON OF TEMPERATURES AND THERMAL STRESSES FOR VARIOUS MATERIALS

1 INCH DIAMETER, 10° WEDGE ANGLE, 60° SWEEP.
$W/SC_L = 100 = 0.9$ 22,000 fps 241,000 Feet

Material	Temperature, °F Maximum	Minimum	Thermal Stresses, psi Tension	Max. Tension	Max. Compression	Tension (Bending) Ultimate Average	99%	Compression Ultimate
¼ Ti Alloy of Molybdenum	2,620	2,070	2,260	7,500	26,100	26,000	.....	17,000
obium Alloy	2,810	1,980	2,200	2,960	4,700	25,000	.....	..0
nse Silicon Carbide	3,060	1,840	2,100	10,350	25,000	18,000	6,920	52,000
ated Graphite, Type I	2,660	2,100	2,240	420	1,610	6,000	1,130	12,000
ated Graphite, Type II	3,290	1,770	2,100	1,620	15,900	4,350	800	.....
rmet, Type I	2,960	1,880	2,140	4,420	690+	46,500	34,400	0
rmet, Type II	2,960	1,880	2,140	5,200	9,650+	65,000	46,400	3,000
lybdenum Disilicide	3,040	1,850	2,120	4,930	2,780+	28,700	14,700	4,500

* For non-metallics measured bending strength on ¼" x ¼" x 5" specimens has been used for tension and compression stresses were taken equal to 3 times the bending values. For metals tension and compression allowables were assumed equal. Since scatter is small only average values for metals are used.

+ Values are low because modulus of elasticity becomes extremely low. In general this would indicate large plastic deformations. Therefore, stresses do not indicate a true picture.

r molybdenum, they said, is vapor-eposited silicon, which reacts with the etal to form molybdenum disilicide. he final coating is a graded mixture "alloy" composed of relatively pure olybdenum disilicide on the outer rface with greater concentrations of se material distributed through it as e proceeds below the surface, they plained. The bonding is chemical.

Silicon carbide is an exception nong carbides in that it is quite re-stant to oxidation. Like all carbides, licides and graphite, it has a high elting point. Anthony and Pearl re-rted that silicon carbide modified aterials, made experimentally by hot essing techniques, have modulus of pture of about 70,000 psi at 2500°F.

The **Carborundum Corp.** says it oduces a self-bonded form of this bstance (KT silicon carbide), which ins only 0.51 mg/sq cm in 5 hours oxidation when exposed to air at 92°F. Carborundum says the ther-al conductivity is 293 BTU/sq ft/-/hr at 1832°F, much higher than ost other ceramics and non-metals.

Graphite has high thermal conduc-ity and high thermal emissivity. hus, Anthony and Pearl reported, an ception is made to the general rule at it is undesirable to coat a ceramic aterial with another ceramic to pro-ct it against oxidation. Graphite also s desirably low modulus of elasticity d coefficient of thermal expansion. lthough its mechanical strength is ry low, it increases with tempera-re up to about 5000°F. Present rms of graphite do not approach eoretical density; thus it is expected at the mechanical strength will be creased in the future.

They said coated graphite is su-erior because of low weight, easy bricability and low modulus of elas-city. However, its strength is variable d the coatings are unreliable.

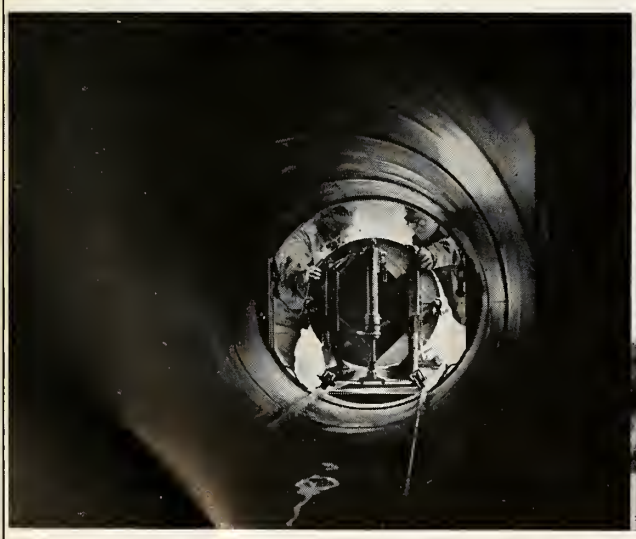
The investigators sought to obtain ata on material with the same process istory. Although it might seem that some information is available from technical literature and need not be obtained again, they pointed out that different processing can result in different properties. For example, they asserted that the effect on mechanical and chemical properties of applying a coating to a material may vary considerably from those of the bare metal.

• **Other materials tested**—In addition to the materials mentioned, the Bell engineers also tested a ternary niobium alloy, pure tungsten, silicon carbide bonded graphite, cermet type I (chromium, molybdenum, aluminum oxide), cermet type II (chromium, tungsten, aluminum oxide) and molybdenum disilicide. Tables I and II give the resulting thermal expansion data and comparison of temperatures and thermal stresses for the materials. Figs. 2 and 3 show thermal conductivity and thermal expansion plotted against temperature for each of the materials tested.

Below about 2400°F, Anthony and Pearl noted, niobium alloy appears to be advantageous because of lower density compared with molybdenum. For high emissivity, a coating would be necessary but the protective oxide formed would make it unnecessary to have oxidation protection of expendable components. However, protection of reusable components would be necessary to avoid embrittlement caused by subsurface contamination.

The two cermets have similar properties except that their thermal conductivity is lower than niobium. Thus, operating conditions would have to be less severe.

Molybdenum disilicide is also promising for temperatures up to 2400°F, they declared. This substance does not need a coating because it has a relatively high thermal emissivity, about .8, and its oxidation resistance also is excellent.



The Bell engineers said tungsten and coated graphite appear to be the most promising materials for use above 3100°F. But they added that much work is needed to advance the state of the art to the point where the materials can be used with confidence under such conditions. They noted, however, that for the leading edge of a boost-glide airplane of global range, temperatures ranged from 2600° to 3100°F for the materials considered.

Anthony and Pearl called for continued development in materials. Specifically, they urged more thorough definition of properties, improvement of processing techniques to reduce variability—particularly non-metal strengths, oxidation protection of coatings and extension of fabrication capabilities.

TABLE II THERMAL EXPANSION DATA

Material	Temperature Range (F)	Unit Expansion (in/in x 10^{-3})	Coefficient of Thermal Expansion (in/in°F x 10^{-6})

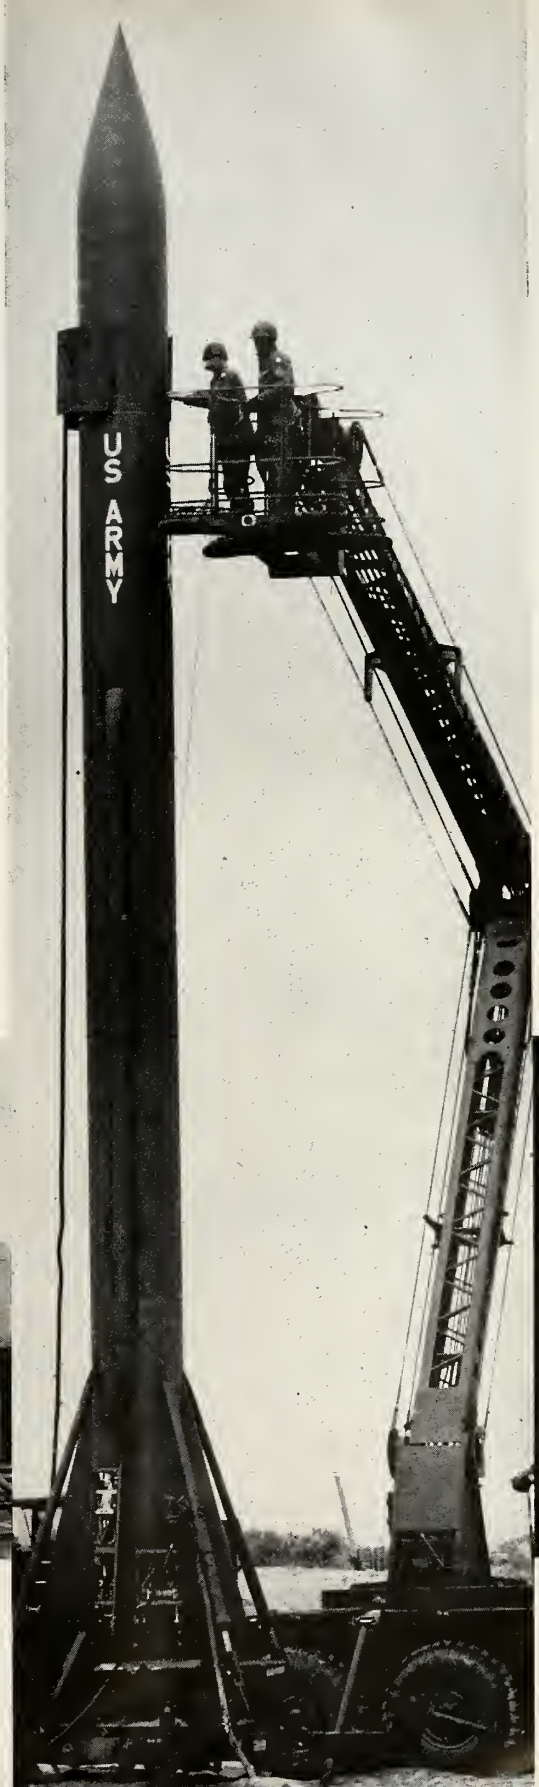
About the earthly side of the Corporal missile. The Army's Corporal mis sile is a surface-to-surface mobile artillery weapon. It's operational and it' in production. Tremendous quantities of materials fabricated into numerou pieces of ground support equipment operated by Army personnel are require to launch the Corporal with split-second timing and accuracy. And virtuall all of the steel material required can be purchased from one source — Unite States Steel. Whether we're talking about carbon steel, high-strengt low-alloy steel, alloy steel or Stainless Steel, steel fence, electrical cable

How thin and light can you make the shipping container for a rocket, and still have a strong, impact-resistant shell? The transportation industry specialists in strong, lightweight construction have overcome this same problem with the help of United States Steel.



This Corporal transporter is made of steel. Why? Because this has to be a rugged piece of equipment to withstand the abuse of moving the missile over all types of rough terrain.

cement or wire rope, United States Steel maintains the technical services to provide the proper assistance to cope with any problem on these materials for ground support. When a ground support program is ready for the drawing board, consult **United States Steel**

USS is a registered trademark

Technicians are carried to the "brain" of the Corporal missile on a "cherry-picker." Its boom is similar to that of an industrial crane. United States Steel representatives are constantly working with the manufacturers of cranes and power shovels to develop more efficient strength-weight ratios and better rigging.

Where Are We Going in Fuel Handling?

The cryogenic engineer still must be a jack-of-all-trades with industry having to gear up for multi-million-pound thrust boosters

by S. David Pursglove

WASHINGTON—The past year has seen many developments in propellant handling. New equipment and new materials such as corrosion-proof alloys and plastics already have been discussed in "new product" sections of magazines, and they have been widely advertised.

The developments we want to discuss here, however, are not machines and materials as much as ideas and techniques. Much of the equipment announced recently probably will be replaced by newer products before too long. However, the recent thoughts of missilemen—some pointing to new trends in thinking—will stay with us and should be examined.

The missile industry has encountered new problems, too, during the past year. However, even these problems represent progress: they signify that engineers are discovering and describing their problems—a first step toward solving them.

Solutions still call for brute force engineering at many stages; there's no easy way out yet. The cryogenic engineer, for example, must be an intellectual jack-of-all-trades. He must understand heat transfer and liquid flow. He has to know all about pumps, instrumentation, and the properties of his materials. Engineers still are faced with the problem of accurately topping a tank of cryogenic oxidizer, although a fairly new device now makes the job a little easier.

The industry is still faced with the nightmarish task of gearing up for multi-million-pound-thrust boosters and their formidable handling problems. This has introduced a new type of handling problem. It's no longer a matter of getting a missile to a launch site and then worrying about fueling it. Soon, the problem of moving the missile to the site will be just as big as—possibly bigger than—the fueling problem. This applies to solid-propellant missiles as well.

Cryogenic engineers must be at home in these areas:

- **materials properties**
- **insulation techniques**
- **liquid flow**
- **pumps**
- **heat transfer**
- **instrumentation**

For that matter, we don't have to wait for the advent of super-size solids to see that the old argument that "solids don't have any problems like liquids do" is out of date and not true. In the past year there has been such a clamor for greater sophistication in solid-propellant missiles that a whole new area of handling-engineering is opening up.

High-energy fuels based on boron still offer problems, but these soon may be solved by the simple withdrawal of boron from the fuels picture. The same is true of free radicals. In the past year it has become obvious that free radical propulsion is on the way out.

• **Real breakthroughs**—On the positive side of the picture for the year past, things are very bright. Thinking has been penetrating and dynamic. Many of the developments to which newspaper writers have applied the term "breakthrough" really have been genuine breakthroughs.

One of the most important events recently is something that built up over a period of time, and without fanfare. It is the unspoken, but nevertheless definite, acknowledgement in missile circles that LOX will continue for a long time as our primary oxidizer. This allows the kind of advance planning that has not been possible while there has been so much talk about replacing liquid oxygen with various "exotic" oxidizers. Eventually, fluorine may take over in some missiles, bu this still is in the future—and probabl on a limited scale.

The National Bureau of Standard has made it possible for liquid hydro gen to be handled much like an other cryogenic. This gives new hop to scientists and engineers who war to use H_2 as the "ultimate fuel." Ne high insulation powders and vacuur insulating techniques further the caus of liquid hydrogen, as well as help th entire cryogenic propellant field.

As an example of some seriou thinking that has been devoted to pro pellant handling problems, engineer point to **Arthur D. Little's** announce ment of a large-scale cryogenics se vicing system. And, almost witho fanfare, the National Bureau of Stanc ards got its cryogenic data cente under way.

The cryogenic engineer still mu be at home in many fields, but abov all, he must be an engineer. He mu know approximately the same thing that are known by an engineer wh designs home refrigerators, but th emphasis has to be different.

Robert B. Jacobs, chief of the cry ogenic equipment section, Nation Bureau of Standards, has this to sa in the April ARS Journal:

• **Principles the same**—"Cryogeni problems can be solved through appl cation of the same basic principle which have been successfully employe for many years in mechanical, chemic and electrical engineering. Situations i which new principles (e.g. supercon ductivity) arise are very rare. No mally, the significant deviations cryogenic problems from the mor familiar ones are caused by chang in emphasis or differences in order magnitude; design difficulties are usu ally the result of insufficient knowled of properties of materials."

As an example, Jacobs suggests th the engineer who understands the bas phenomena occurring in a centrifug

ump can predict performance and avitation characteristics for a liquid ydrogen pump just as reliably as he an for a cold water pump.

Although the differences between old water engineering and cryogenic ngineering may be only differences in mphasis, they are very important. acobs points out that the engineer ho designs valves for operation at mbient temperatures is interested in ydraulic efficiency and leak tightness ross the seat and through the stem acking. When he takes on the design f a valve for handling a cryogenic ropellant, he has the same interests, ut some become more important: dif-erential contraction, freezing of pack-ng materials, impact strength, insula-on.

Jacobs points out six areas in hich the cryogenic engineer must be articularly well versed:

• Materials properties, not too ritical at room temperature, become ll-important at extremely low tem-eratures. In missile work, low tem-erature strength is needed and, with-the missile, material density be-omes important.

• Insulation techniques have to be familiar to the cryogenic engineer his own name. He must be on inti-ate terms with conventional, powder, nd vacuum techniques. In ground andling of propellants, he has to de-de between insulation and no insula-on—sometimes no insulation is pre-rred for the sake of economy and eed. It is up to the cryogenic engi-eer to make the decision.

• Flow of liquids is a function of any considerations, all of them ap-lying equally to ambient temperature nd cryogenic engineering. Cold flow resents additional problems involving ansient phenomona that take place uring cryogenic equipment cool down.

• Pumps, and what happens to em at low temperatures, must be nderstood thoroughly. The problems volved in pumping LOX are about e same as those involved in pump-g cold water, at least on paper. But acobs feels we need additional studies to cavitation characteristics.

• Heat transfer considerations are ll-important in cryogenic engineering, ut do not involve any new principles. owever, Jacobs warns of contradic-ons between much published heat ansfer data.

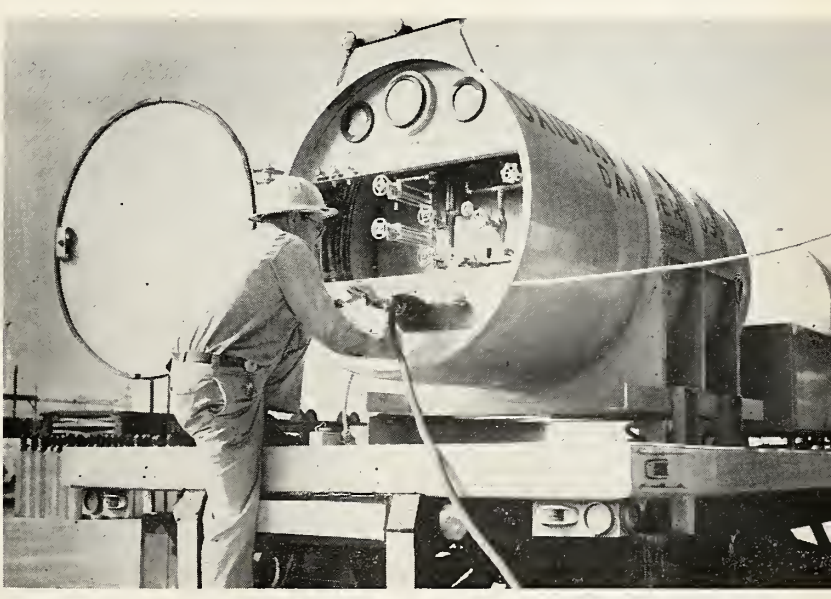
Instrumentation is an important ea for the cryogenic engineer con-rned with fueling a missile. His udies of instrumentation must be anted toward pressure, temperature, ow, liquid level, and static mass easurement. Cryogenic instruments, nd the materials of which they are made, have to take into account the effects of low temperature and high vacuum.

Jacobs makes it relatively easy for the cryogenic engineer to bring himself up-to-date in his field through a 56-entry bibliography of references in his survey of "Recent Advances in Cryogenic Engineering. Particularly valuable are these references: a new book published this year by D. Van Nostrand, "Cryogenic Engineering," by R. B. Scott; a series of articles by R. J. Corruccini, "Properties of Materials at Low Temperatures," in *Chemical Engineering Progress*, June, July, and August, 1957.

The Cryogenic Data Center is now in operation at the Cryogenic Engineering Laboratory, National Bureau of Standards, Boulder, Colo. Its purpose is to make information available to all persons concerned with cryogenics. Jacobs says it probably will not be completely up-to-date for about two more years, but it is currently rendering whatever services it can.

• **Fill 'er up?**—It may sound strange, but one of the biggest problems still faced by missilemen is that of filling a missile tank to the top with a liquefied gas. Assume all handling problems have been solved, then it's fairly easy to fill a tank part of the way. It's another thing to fill it all the way, or to top it.

Daniel A. Heald, senior design engineer at **Convair Astronautics,** described the problem recently to a meeting of the Society of Automotive Engineers. For example, he says, a missile's mission may call for rapid loading and firing. It seems like a small enough problem to get 0.5% accuracy on propellant weight at launch, or to fill the LOX tank to 98% of capacity to assure maximum range.



Just try to do it. Here is what Heald says we run into with a missile system with a large vertical airborne tank:

"The ground loading system, which must be considered an integral part of the whole, is a remote, high-capacity system with extensive automatic controls. Why not just weigh the filled missile on load cells, which have an advertised accuracy of 0.1%? This approach may have to be abandoned when one considers that the gross weight of the launcher system may nearly equal that of the missile, that misalignment of the missile and forces from cross winds introduce appreciable side loads which necessitate lateral load cells and complicate resolution of weighing systems, that calibration of such a complex system is difficult, and accurate load cells are expensive, and temperature sensitive, and that the propellant is rapidly boiling away."

Heald had developed a more practical technique:

"Calibrate the vessel so that the volume is known for a given liquid height; then knowing the density and level, the propellant load can be calculated."

This still leaves the problem of boil-off, but even that has been partly taken care of by a LOX tanking computer that **Servomechanisms, Inc.,** put into production around a year ago. SMI says the tanking computer meas-

SIGNIFICANT advancement in the transportation of fluorine both in liquid and bulk was made by General Chemical which designed this trailer transport.

Little tackles fueling time . . .

ures, controls, and indicates the level of LOX in tanks.

Loading is rapid and accurate, SMI says, due to a two-mode control system. The first mode permits high pumping rates until 98% of tank capacity is reached. Then the second mode takes over and controls a proportioning valve which adds the LOX necessary to fill the tank to within 0.1% accuracy. The second mode also provides continuous topping during standby to compensate for boil-off.

• **High-speed effort**—The problems involved in handling cryogenic liquids are at the bottom of most valid arguments against liquid-fueled ICBM's. Thanks to these problems, liquid fueling times are longer than we can afford in case we need to use missiles for retaliation.

In 1955, the Air Force asked **Arthur D. Little, Inc.,** to study fueling time problems and try to develop a reliable high-speed fueling system. A. D. Little's R. B. Hinckley and R. E. Kendall described the resulting system at the San Diego meeting of the American Rocket Society in June.

The system had to meet these requirements:

(1) Be capable of loading an *Atlas* within the available reaction time (interval between detection of a hostile ICBM in flight, and the time of its impact on target). This meant it would have to be capable of LOX transfer rates up to 5000 gpm, and fuel transfer rates up to 3500 gpm.

(2) Be fully automatic to eliminate human error and relieve control personnel of routine detail.

(3) Use only standard, off-the-shelf industrial components.

(4) Load the missile to an accuracy of 0.5% by volume.

A. D. Little discovered that the largest proven LOX pump available had a capacity of only 500 gpm—10 pumps in parallel would be required.

The research firm decided not to use pumps at all, but to use a pressure transfer system instead. Thus, the key to the system involves transferring the LOX under a pressure head of gaseous oxygen. Helium was ruled out because of the then national shortage which is being slowly alleviated. Nitrogen was ruled out at the time because of the unknown effect on LOX of nitrogen contamination due to nitrogen condensing in contact with the LOX. Subsequent studies at A. D. Little show the nitrogen contamination not to exceed 0.5%, Hinckley and Kendall report.

• **Good results**—Tests were run at Edwards AFB. A dummy missile LOX tank was used. Here are the results:

The system demonstrated fully automatic loading, topping and draining. LOX flow rates were greater than 5000 gpm, and transfer pressures were lower than expected. The system was controlled to an accuracy of 0.5%. The system could be cooled down in the time available—critical parts of the system were cooled sufficiently for transfer in less than three minutes. The topping system maintained the LOX level, and even changes in wind velocity resulted immediately in a new topping valve position. The system is fail safe as proved by deliberate malfunctions.

The system is applicable to fuels as well as LOX. It probably will be applicable to other oxidizers, too. However, it may be a decade or more before anybody has to start worrying about wide-spread operational transfer systems for other oxidizers. In the past year, whenever the matter has come up, industry leaders and top military officials have said, or strongly hinted, that LOX will be the operational oxidizer in our missile program for some years to come. It still is the safest, most economical, most readily available oxidizer for missile use. It is stable, non-toxic, non-corrosive and, in an emergency, it's easy to get rid of.

• **Future and fluorine**—However, surveys of this sort always end with a look at the future. That which has been said about LOX does not den that fluorine someday will find use a an oxidizer for some missions. Thi day is coming closer, thanks to **Be Aircraft's** continuing study of fluorin and thanks to **Allied Chemical's** ne developments in fluorine handling (se M/R May 11, p. 42).

Allied makes it possible to sh liquid fluorine almost as readily a LOX. However, it still is a dangero substance when it escapes, calls f special handling techniques at laun sites, and is corrosive. But NASA hard at work trying to develop ne materials that can take the punishme of liquid F_2—materials immune gaseous F_2 already are available.

Fluorine may someday be one-ha of a system already touted as the gre chemical propellant system we'll ev have—fluorine-hydrogen.

Just as the past year has seen r markable advances in fluorine handlir techniques, so have many of hydrogen problems been conquered. **Linde Con pany's** new super insulation techniqu make liquid H_2 storage easier. Hov ever, the real breakthrough has be discussed in M/R's Propulsion Eng neering many times. That is the ne National Bureau of Standards proce for converting unstable hydrogen stable hydrogen, thus eliminating bo off due to heat released in the natur transition from the unstable form the stable form.

Converted liquid hydrogen stor in Linde Company's new super ins lated tanks almost never boils away.

The theory is there. Now we ne hard-headed engineering and we'll ha an unbeatable propellant system. Har headed engineering, money and time

OUTSTANDING cryogenic research is being undertaken by the NBS-AEC Cryogen Engineering Laboratory in Colorado.

BRITISH ASTRONAUTICS

- **Pye Ltd. Develops Tank Missile**
- **Corporal Fired from New Missile Range**
- **Scorpion Engines Extending Aircraft Life**

by G. V. E. Thompson

LONDON—One of Britain's leading lectronics manufacturers, **Pye Ltd.** of ambridge, has developed a powerful hort-range guided missile intended to eplace the armour-destroying heavy un currently carried by tanks. The 0 lb. missile has a 5 ft. tailless body tted with cruciform wings, and is jet- eered. Simple and robust in construc- on, it is also easily stored and has a ng shelf life.

The size chosen is thought to be e best compromise possible between e requirements of ease of handling d high chance of kill per hit. The issiles can be transported in quantity a light vehicle, from which they can e fired. Alternatively, it can be car- ed by one or two men for short stances and ground-launched, firing d control needing only one man.

In either case, launching is from lightweight, zero-length launcher built om tube. Line-of-sight command con- ol is employed; the controller can use noculars or a periscopic monocular hich can be switched instantaneously om low to high power magnification ithout loss of target reference as the issile travels away from the launcher.

The control is a simple hand-held ystick. Its signals are shaped in a) lb. ground control unit and trans- itted to the missile by a wire link. he control unit can launch and con- ol several missiles consecutively. Op- ation of the joystick needs little skill; simulator is being developed as a aining aid, but one of the advantages the weapon system is that only a ort practice time is needed to achieve oficiency.

• **New missile range opened**—A w British guided weapons range has en opened. It is situated in South ist in the Outer Hebrides, a group islands off the West coast of Scot- nd. There was considerable contro- rsy when the establishment of the nge was first suggested, most of the jections being on account of the anges in the primitive way of life on e island that would follow. However, any of the crofters themselves seem to have welcomed the employment that the construction of the range has provided.

The first missile to be fired from the range was a *Corporal*, supplied in 1956 by the U.S.A. for use with the British Army. Apart from two civilians from the American manufacturers, all the personnel taking part in the firing were drawn from the Army: and had been trained at the School of Artillery, Larkhill.

The first *Corporal* carried an inert warhead and travelled for more than 50 miles over the Atlantic Ocean. In wartime, Britain's *Corporals* would be fitted with nuclear warheads supplied from America.

• **Napier's rocket engines**—The *Scorpion* series of rocket engines built by **D. Napier & Son Ltd.**, members of the **English Electric** group, are being used as powerplants for both missiles and aircraft. They work on the "thermal ignition" principle: high-test peroxide is catalytically decomposed into superheated steam and oxygen; this mixture enters the combustion chamber at high temperature and pressure, kerosene is injected and ignition occurs spontaneously.

Single, double and triple-chamber engines are in production; all have the advantages of compactness and low weight. Routine testing of pre-production engines at altitudes of up to 70,000 ft. and temperatures of −70° to +40°C has been done in a Canberra jet bomber fitted up as a flying test bed.

The flexibility and precise control overthrust possible with *Scorpion* makes it ideal for powering target missiles. It is also suitable for air-launched short to intermediate-range missiles, such as the "stand-off" bomb.

Single *Scorpion* engines are installed as boosters in present-generation interceptor fighter aircraft, the HTP being carried in nitrogen-pressurized underwing tanks. For the "last-generation" all-weather fighters (such as English Electric's Lightning), Napier's have designed a rocket power pack that is interchangeable with the standard long-range kerosene tank carried by the aircraft.

The pack attaches to the aircraft at two points, is of skin and stringer construction and incorporates a Double *Scorpion* engine. HTP is carried in an integral tank forming the front part of the shell of the pack, and kerosene is drawn from the tanks of the aircraft. On the top of the pack is a kerosene inlet, a nitrogen-charging connection and the electrical connections to the control panel in the cockpit.

In combination with the advanced air-to-air missiles now being developed, this power pack is expected to give the semi-obsolescent fighters a new lease of life.

• **Short** *Seacat*—For many years the standard close-range weapon of the Royal Navy has been the 40mm gun. This is now to be replaced by the surface-to-air missile *Seacat*, now being developed by **Short Brothers & Harland Ltd.**, of Belfast, Northern Ireland.

News that Short had been awarded a development contract for *Seacat* was first released in April, 1958. Two months later, speaking in the House of Lords, the First Lord of the Admiralty described *Seacat* as a most ingenious weapon with a novel type of direction which gave very high promise. In Dec. 1958, the Parliamentary Secretary to the Admiralty indicated to the House of Commons that there would be a considerable number of these missiles in service by the early 1960's.

Security on *Seacat* is still strict, but a full-scale model of the missile and a film of a test firing were shown for the first time at the recent Paris Air Display.

Powered by a solid propellant motor, *Seacat* is designed to be instantly ready to repel attack and is highly maneuverable. Apart from its use by the Navy, it will also provide an anti-aircraft armament for small ships.

A variant of the missile is being developed for use by land forces as a replacement for light field artillery. This is to be known as *Tigercat*. Several Commonwealth and N.A.T.O. countries have expressed interest in both missiles.

Detection of Nuclear Explosions in Space Possible by Optical Means

Two spectroscopes mounted in satellite proposed as method of surveillance

by Savo Ćorić

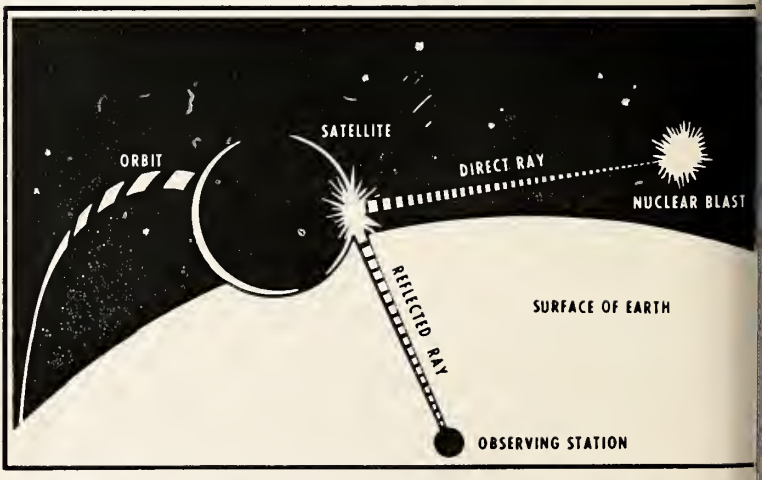
KOBLENTZ, GERMANY—Were it not for the existence of Van Allen radiation belts and solar flares, detection of nuclear explosions in space by means of orbiting satellites equipped with radiation-measuring instruments would be relatively simple. For space is a near-void in which radiation and fission products from such an explosion expand freely without any hindrance—unlike the earth's atmosphere, where they remain confined to a limited area.

In the radiation belts, however, any man-made radiation may pass unnoticed because of the very high level of radiation of the belts themselves. For this reason, an existing project, designed to supervise space with orbiting satellites in case an agreement on a nuclear test ban is reached among the nuclear powers (U.S.A., Great Britain and U.S.S.R.), would not attempt to send satellites into the radiation belts.

It plans instead to orbit six satellites below radiation belts (under 600 miles) and six others above the belts—in a 40,000-mile orbit. Each satellite should be equipped with Geiger-Mueller and scintillation counters to pick up gamma and neutron radiation produced in a nuclear blast. The satellites' radio transmitters would then broadcast the findings to an international network.

But a nuclear explosion produces many other phenomena which might possibly be used for more reliable and efficient detection. If, for example, the radiation-counting instruments of the aforementioned and similar projects were replaced or supplemented with optical instruments using spectral analysis to analyze the optical phenomena particular to a nuclear blast, the detection of such blasts would be by no means hampered by radiation belts.

• **Advantages**—The proposed optical detection would have following advantages over radiation-counting methods:



1. Blast-monitoring satellites could be launched into much lower orbits, that is with much less fuel and by much smaller rockets;

2. Reliability. Radiation-measuring instruments would be swamped, even above the radiation belts and at auroral latitudes up to any altitude, by charged particles hurled into space by solar flares. So it would be easy for a would-be violator to carry out undetectable nuclear-weapons tests one or two days after such a solar flare has been observed on the sun—when the oncoming solar gases reach the vicinity of earth. The proposed optical detectors would, of course, not be affected by such radiation; neither would they be optically fooled by such flares or any other light flashes unrelated to a nuclear blast;

3. Aided by favorable atmospheric conditions (i.e., a good visibility) th optical detectors would also detec nuclear blasts taking place in the atmos phere and even on the ground.

• **Details**—T h e optical-detectio equipment would be mounted in spinning satellite. It would consist o two spectroscopes viewing the spac through the same slit. Each spectro scope would be followed by a scree and a photoelectric sensor (a photocel or a solar battery).

One screen would be pervious onl to such Fraunhofer lines of the sola spectrum which would be identical wit the lines of the emission spectra of th most abundant chemical elements o the nuclear bomb or its fission prod ucts (uranium, plutonium, barium, etc.) the other screen would let pass to it sensor only those Fraunhofer line identical with spectral lines of som chemical elements not to be foun either in a nuclear bomb or among it

EXPLOSIONS far off under the horizon could be detected by receiving the flash reflected by the outer surface of the satellite.

ission products in appreciable quantities (the Fraunhofer lines are not dark, hey only appear so in relation to much righter continuous solar spectrum).

Furthermore, the Fraunhofer lines eaching both sensors must be selected o prevent detection equipment from he influence of either atmospheric or errestrial light sources, natural or rtificial, which emit line spectra aurorae, lightnings, ionized vapors of lisintegrated meteors, extended fires, as-discharge lamps). Thus these Fraunofer lines will not be identical—at sual temperatures of the light sources —either with the spectral lines of the onstituents of the atmosphere or with he lines of the chemical elements to e found in meteors, in organic compounds or in the plasma of a glow amp in appreciable quantities.

This means that both sensors will e sensitized by solar spectrum and he spectra of terrestrial and atmospheric light sources which emit a continuous spectrum (incandescent lamps, ncandescent solid meteors), while only ne sensor will respond to the line pectra of the nuclear bomb components and its fission products.

The outputs of two sensors are mplified and connected to a differential ircuit where the pulses provoked by he solar spectrum—as well as those enerated by the continuous spectra of errestrial and atmospheric light sources —cancel and only such pulses which re produced by the spectrum of a uclear explosion pass to the transitter. They are either transmitted imediately to earth or stored on a magetic tape for later transmission.

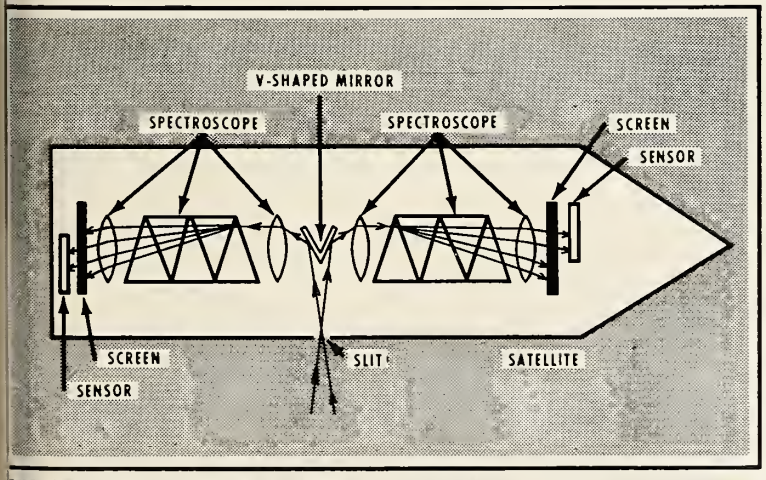
The differential circuit could consist of a simple transformer with two rimary windings connected in phase pposition. Each sensor would feed one primary winding and all pulses which are common to both sensors, that is those produced by the solar spectrum, cancel while only the pulses generated by the nuclear explosion would be transmitted to the secondary winding of the transformer.

By this means, changes in the luminosity of the received sunlight, caused both by the changing attitude of the spinning satellite and the optical phenomena on the sun itself (i.e., sunspots and solar flares), would not influence this detection equipment for their effects would always cancel in the differential circuit, and only the pulses produced by the spectrum of a nuclear explosion would be recorded.

This detector will be influenced not only by the emission but also by the absorption spectra of the nuclear-bomb components. The emission spectra will be provided by the flare of the explosion itself and by the subsequent glow of the ionized vapors of the nuclear-bomb components and its decay products. The absorption spectra will appear when the detector is receiving the sunlight which passed through a "cooled-off," non-glowing cloud of such vapors.

This cloud will absorb only the light of the Fraunhofer lines of the solar spectrum which are particular to the elements to be found in the cloud. These lines will, therefore, appear darker in the detector than the other Fraunhofer lines which are not affected by the vapor cloud. As the former lines are received by one sensor and the latter lines by the other sensor an unbalance will appear in the differential circuit and this unbalance will produce a signal which will be transmitted by the transmitter.

The absorption spectra will thus make it possible to detect later the nuclear explosions which took place while the satellite was out of sight, far off under the horizon. When the satellite is orbiting in the shadow of the Earth this type of detection will be, however, ineffective.



• **Looking around corner**—The same equipment—plus a telescope and a spectrograph—could be used in a ground installation to observe orbiting satellites in quest of nuclear-explosion flashes reflected from the surface of the satellites.

In this case the resulting signal, produced by a nuclear blast in the differential circuit, would trigger the photographic camera of the spectrograph so that the entire spectrum of a nuclear-bomb explosion would be photographed. This would make it possible not only to detect a nuclear explosion but to identify the nuclear device itself—A-bomb or H-bomb. The same spectrogram would also reveal the construction of the nose cone as well as its constituents.

In favorable weather conditions, this method could detect all nuclear blasts in space above and below the satellite itself as well as above the tangent drawn from the satellite to the earth's surface away from the observing station. When visibility was bad, the equipment could be taken up by planes.

All big satellites can be used advantageously for this type of detection and especially the big balloon-satellites (they have the largest surface to weight ratio). The moon itself might be included.

Finally, both types of detection could be used for spotting big forest and prairie fires in remote areas. All that would be necessary would be to replace the screen pervious to the spectral lines of the nuclear blast with a screen transparent for the spectral lines of an element which is found in any organic compound. This is the element carbon.

WO SPECTROSCOPES with associated screens, sensors and circuits would suppress unlight signals and transmit only nuclear blast signals.

Lockheed's X-7 Missile Enshrined at AFMDC

ALAMOGORDO N.M.—The **Lockheed** *X-7* ramjet-powered test missile has been enshrined at the Air Force Missile Development Center in New Mexico where it set the Free World's speed and altitude records for air-breathing vehicles.

It was over the New Mexico desert test range of the AFMDC that members of the Lockheed-designed and developed *X-7* family flew in excess of four times the speed of sound—in the neighborhood of 3000 miles per hour —and reached a record (still classified) altitude at the edge of the upper atmosphere.

Magnetic Tape Recording Sales Booming

This year should see 700,000 units sold but most promising future application will be in astronautics for photo-reconnaissance

by Robinette E. McCabe*

REDWOOD CITY, CALIF.—One of the fastest growing industries in the United States is the magnetic tape recording industry. Since the appearance of the first tape recorder on the American market just twelve years ago, few devices have spread so far so fast.

Its success is attested by today's status of the industry, which has mushroomed into a multimillion-dollar business, with gross sales for 1958 exceeding $72,000,000 for 410,000 units, according to the **Electronic Industries Association.** Although future estimates vary, it has been predicted that between 650,000 to 700,000 recorders will be marketed in 1959, boosting overall sales to $140,000,000.

First adopted for radio and home entertainment purposes, the tape recorder has spread in all directions until now it is a basic tool for advanced scientific activities, contributing heavily to research and military programs in missile development, satellite tracking, and related laboratory instrumentation procedures. Less known than for its brilliant entertainment contributions, this complex area holds great promise for the future of magnetic tape recording.

Tape equipment manufacturers refer to this area as the "instrumentation" field. These applications have been a major factor behind the recent burgeoning of the industry, and current trends indicate that the next few years will bring even more extensive progress in this direction.

The fertility of this field can be shown from the growth of the **Ampex Corporation** whose concentration in this area accounted for 50% of the total instrumentation sales in the United States in 1958. Less than ten years ago, the company was doing a gross annual volume of $350,000 a year. In 1958, the company's volume was $44 million.

• **Forces behind use**—Like any major development, the application of the magnetic tape recorder in such a spectacular manner has been the result of a practical as well as theoretical expediency. By the end of World War II, a storing element—a "gadget with a memory"—was badly needed: scientific, industrial, and defense agencies were swamped with data vital for emergencies and the solution of immediate problems.

The technical advantage of magnetic tape as a recording medium is attributable to:

1) Its capacity to record any phenomena which can be converted to an electrical impulse, over a wide frequency range with minimum distortion.

2) It will store more information per unit length than any other medium.

3) It requires no processing (no chemicals are required to *develop* it), and thus immediate reproduction is possible.

4) The time base can be altered—which is something no other medium provides. This permits events to be recreated on playback either faster or slower than they actually occurred (using a 10:1 contraction rate, for example, an hour of missile test recording can be reproduced in 6 minutes).

In many cases, these four characteristics of the tape recording process permit the attainment of results which cannot be achieved in any other way.

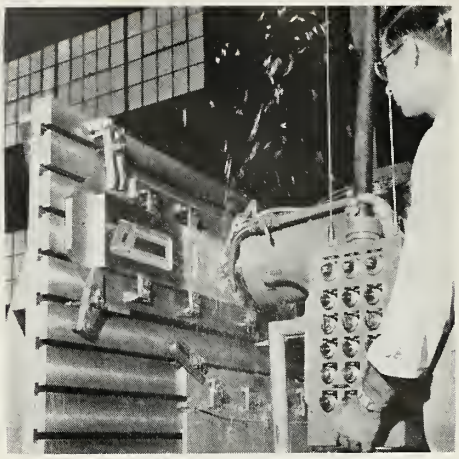
• **From wire to tape**—The first magnetic-recording device was demonstrated experimentally at the Paris Exposition in 1897 by Valdemar Poulsen, a Danish scientist. Acclaimed the electrical marvel of the age, it nevertheless remained relatively obscure and undeveloped until World War II.

During the war, both U.S. a German scientists attempted to repr duce magnetic recorders suitable f military use in recording sound a coded messages. The Americans co centrated on developing a wire corder, but the Germans concentrat on magnetic tape. When Germany s rendered, Allied technical teams d covered magnetic tape recorders many of the enemy's military and gc ernment broadcast installations.

Several units were shipped to t United States where it was demc strated that magnetic tape had greater versatility than wire. For o thing, tape can be edited. This is r feasible with wire since it cannot spliced without distorting the magne signal. And, where ease of manipu tion is a major factor, the reason tape's popularity is obvious.

The first practical recorders audio use were introduced in t United States in 1948. The units we immediately successful and thousar of machines were installed in broadc and sound studios.

• **Instrumentation next**—Almo simultaneously, missilemen recogniz the potential of magnetic tape. In l 1948, the Naval Air Missile Test Ce ter at Point Mugu, California, had audio-type recorder modified for te metering and used as a "back-u or check, for strip-chart recorders. soon became the primary method recording the missile flight test data acceleration, fin flutter, rate of f consumption, flight curves, tempe tures, and a dozen other vital elemen



The problem in the missile fi was clearly defined: more and mc information in less and less time. T manufacture of tape and other reco ing components was sufficiently a vanced to meet the need. Magne tape's pre-eminence for this testi rests in its ability to capture millic

* Ampex Corporation.

← **AMPEX MR-100 tape survived *Thor* flight and nine days exposure in Atlantic.**

→ **RECORDERS are being used extensively for machine control. Here's close up of Giddings & Lewis Profiling Machine.**

f separate measurements in relatively hort periods of time. Receiving the utput of dozens of transducers on and ithin the system, it can be used to easure almost any variable at any oint.

• **Development**—To accommodate issile requirements, an intensive delopment program (which is still goig on today) was undertaken. Because he amount of information that can be tored per unit length of tape depends n the width of the tape and the numer of tracks on which the data is nscribed, bandwidths were increased rom the normal 15 kc, which is satisactory for audio use, to 100 kc and eyond.

Tape widths were increased from 4 to 1 inch, which is the width of ost computer tapes. (For most instruentation purposes, 100 kc and 1″ pe is satisfactory, although in teleision recording bandwidths as high as megacycles can be recorded successully, and 2″ wide tape is used.)

The upward trend in channels of nformation increased from a single hannel, to 7 channels, to 14 channels, o 16 channels, and to 32 channels per nch of tape.

The tape speed was increased for wo reasons. First, because the amount f data that can be inscribed per unit f time depends upon the speed of the ape and, secondly, because high ransfer rates for computer and telemery applications demand higher speeds. Although the speed at which tape noves past the recording head in home achines is generally 7½ or 3¾ inches er second, tape handler speeds are as igh as 150 ips for computer and elemetry use.

The result of the improvements is n evidence at missile testing installaions. In a typical use, a single facility or handling test data transmitted from *Atlas* and *Thor* ballistic missiles, utilizes 23 laboratory-type instrumentation recorders and is capable of correlating as many as four million measurements in three days' time.

Additionally, it has proven to be an instrument of immense scope in the missile field for it is used in several ways.

• To guide the missile. It activates electronic devices which control the path of the missile.

• To recover information from space. Miniature missile recorders ride in the missile nose cone and radio outer-space information back to receiving stations.

• For data reduction. The recorder is used with computers and other automatic data-handling devices to reduce the data to usable form.

Sizes and weights of these recorders vary according to their specialized purposes, but all of them are rugged. One sturdy little missile recorder recently survived a U.S. Air Force missile flight and 9 days in the Atlantic Ocean, yet was able to perform perfectly when retrieved from the water and tested. Used on a *Thor-Able* missile flight that carried a **General Electric**-developed plastic sphere, the recorder was imbedded in the nose cone. Before the cone struck the water, the recording unit was thrown free to fall independently.

Surviving the tremendous vibrations and shock of the launching and re-entry periods, as well as exposure to the water, it performed to specifications as soon as a new tape reel had been installed.

• **Flight testing**—Magnetic tape nearly revolutionized data acquisition for aircraft flight testing programs. In the early days of flight tests, the pilot would read the instruments on his control panel and note his observations on a pad strapped to his knee.

As design techniques were refined, test engineers required more extensive data and introduced more automatic methods of data acquisition to free the pilot from his primary mission of flying the plane. Measurements were brought to dials mounted on a panel which was photographed by a motion-picture camera. Pen-and-ink graphic recorders and other devices permitted continuous recording of high-frequency information, such as vibrations and flutter.

Many of these techniques are still in use today and serve a purpose. But, as in the missile industry, the demand for more and more measurements and a more rapid reduction of these measurements to usable physical quantities upon completion of the flight, required the use of more modern techniques.

Tape's ability to store over 8 million measurements during a 2-hour test flight on one standard 10½″ reel of tape proved so appealing that tape recorders are now used in all major aircraft laboratory and test facilities, both commercial and military. **The Boeing Aircraft Company,** in employing it in the KC-135 jet tanker flight testing, samples each of 420 separate measurement points at the rate of 2.5 times/sec.

If these measurements were to be recorded on photo panels, or on oscillographs, several weeks of concentrated effort, involving large numbers of persons, would be required to reduce the data by manual means before the design engineer would have the significant numbers to either correct or improve the design. In accelerated aircraft programs, time lags of this magnitude are too costly to be tolerated.

• **Machine control**—Also, recorders are being used extensively in the aircraft and missile industries in quite another way. This is for machine control. Because you can electronically record motion on tape, many milling machines

no manual control required . . .

and profilers now take their cues from recording systems.

If you were to walk into a spacious bay at **Convair Division** of **General Dynamics Corporation's** big San Diego Plant 2, you could see a massive skin miller gnawing methodically at a 10′ by 30′ plate, removing 25 pounds of metal in 15 minutes flat. Down the road a few miles at **Rohr Aircraft Company's Chula Vista works,** a horizontal profiler makes metallic mincemeat of a rough aluminum forging.

There is no manual control at either machine, but there is nothing haphazard about the paths followed by the cutting tools. It is instead precision machine tooling, called "numerical control"—or machining by numbers. Like the roll that controls a player piano, magnetic tape provides an accurate system of guidance. Through digital recording, information can be transferred at rates up to 90,000 characters per second, permitting machining techniques far beyond the capability of human hands.

• **Video tape**—But the refined and accurate recording of sound was but the first step. An event almost as great as development of the tape recorder itself occurred in 1956 with the addition of a picture to tape.

The first machine was demonstrated in Chicago at the National Association of Broadcaster's Convention. Despite the fact that the machine was priced at $50,000, it received an immediate welcome in the television industry and now stations equipped with these units are able to reach 95% of the television sets in America.

The addition of a picture to tape was pioneered by the Ampex Corporation which, as of now, is still the only company to deliver production units of television recorders to the television industry.

But even more interesting is the fact that even before the machine was in production for commercial television purposes, the prototypes were sold for instrumentation purposes. One of the first three prototypes went to the White Sands Proving Ground where the Army Signal Corps is using it to track missiles. A highly classified project when it was first proposed, the U.S. Army recently announced its successful use on hundreds of missile firings.

The radar signals are picked up at five stations strung out over the 4000-square-mile range. Because radar signals are in a frequency range still too high to be recorded by any known means without conversion, a radio receiver converts them to a lower frequency. Yet the amount of conversion that can accurately be accomplished is limited, and this leaves the high-frequency radar signals still out of range of most recorders. A Videotape (TM Ampex Corp.) recorder, with a frequency response up to 4 mc, does the job. In the period since this first prototype was pressed into use, many other Videotape recorders have been sold for instrumentation purposes.

Taking a cue from colleges and universities across the country, rocket and missile installations are using them for educational purposes, too. At the Redstone Arsenal in Huntsville, Alabama, for instance, twice each month by means of closed-circuit television, senior Army officers are taught the complicated business of rocketry—a teaching program produced for the Army by the **TelePrompTer Corporation.** One end of the classroom is in Huntsville, and the other end is 278 miles away at Fort Knox, Kentucky.

• **Its future**—Applications involving telemetry (the transmission of measurements), static testing of rockets and missiles, laboratory research, medical recording, and machine tool control form the foundation of today's instrumentation business. For the future, it is expected that it will continue to serve in all of the categories where it is presently being used. Also, it is envisioned that it will radically expand in some of the areas as the government moves toward more missile and space projects, with vast research and development programs geared to these activities.

One of its most exciting future applications will be in space. And the new tape method—magnetic photography—is certain to be used. Even now, plans are being considered for a space recorder for a proposed flight involving photo-reconnaissance of Mars. This test envisions the launching of a rocket from the earth that will take a little over two years before its return. During this time, it will circle Mars, with the recorder photographing the surface as the space vehicle passes by. The photographic information will be radioed back to earth as the space vehicle returns near the earth's atmosphere.

However, the airborne picture recorder will not have to wait for a trip to Mars to prove useful. Equipment is now being built that will permit tape's use for operational missions which include intelligence reconnaissance, weather reconnaissance, and infrared photo-mapping. Since these wi be airborne recorders, with recordin ability only, there will be a correspond ing increase in ground reproductio and data processing equipment fo these missions. Even conservativ studies indicate that this field ma dwarf all previous applications.

It is assured that the testing o military and commercial aircraft—witl its attendant use of the recorder—wil continue over the coming years. It addition, the arrival of the commercia jets for public transportation, brough more business for the recorder. Th Federal Aviation Authority has aske for a jet performance and crash re corder, designed to withstand the intens heat and shock of an accident, for al jet airliners. Also, the FAA may us tape to activate electronic devices use in new air traffic control systems.

• **Problems**—Future space record ing will require surmounting hundred of problems, but today two of th biggest appear to be improved syste fidelity (accuracy of performance), an miniaturization of equipment.

Fidelity limitations of the record ing system are primarily centere around the tape. The mechanical fea tures and electronic component relia bility of the tape recorder can als limit the system, but by far the big gest drive for improvement is centere on the tape, and on the record, re produce, and erase heads which com in contact with the tape. For it is fel that the steady improvement of th magnetic heads may help to overcom some of the inherent characteristics o the tape.

To discuss the problem require some elaboration on the structure o magnetic tape and the recording proc ess. All tape consists of a non-mag netic base which supplies mechanica strength. Since the thickness of th base material varies from 0.0005″ t 0.0015″, it must be of considerable strength or it would support no stress at all.

Favorite base material for instru mentation uses is Mylar, a **Du Pont** manufactured plastic. Chemically, it is polyethylene terephthalate, formed by the condensation reaction between ethy lene glycol and terephthalic acid. A polymer with an oriented molecular pat tern, it exhibits a smooth surface, uni form thickness, and a resistance to high temperatures and humidity. To this Mylar base is added the magnetic iron oxide particles, ground to a micro scopic size. They are combined with a binder and applied to the base with pre cision equipment.

The tiny magnetic heads in a re cording system perform three vital functions. The record head converts in formation—in the form of encoded

electrical signals—into a pattern of magnetization upon the tape. The reproduce head reconverts this magnetization pattern into electrical signals again, to be decoded and put to an array of practical uses. The erase head obliterates old information, leaving the tape clean for further use.

It is an extremely sensitive technique, and herein hides the problem. For, in spite of all reasonable precautions, the surface of the tape does not end up entirely smooth and homogenous. Small defects manifest themselves by instantaneous lapses or reduction in signal level, which are referred to as "drop-outs."

The most serious of these are "nodules" or clusters of oxide particles which form along the surface of tape. As these nodules pass across the head, they cause the tape to be lifted away from the head and result in defective recording. A similar difficulty will occur if a foreign particle of dust is permitted to find its way onto the surface of an otherwise perfect tape.

Illustrative of the reliability problem are the difficulties experienced with Videotape. The extreme fidelity demanded of Videotape, which must accept ten times more information per unit area than audio tape, produced an inordinately high rejection rate when the tape was first introduced.

In addition to achieving a reliable, flawless surface, positive steps will have to be taken to extend tape's environmental limits. The physical properties of Mylar are relatively unaffected throughout the temperature range of −20° to +80°C. It remains flexible without signs of embrittlement at temperatures as low as −60°C.

But as the temperature is increased above 80°C, it behaves like an elastimer, finally melting at about 250°C. Several new resins that appear to be potentially useful have appeared recently. For example, polyurethane, an isocyanate derivative, can be produced in forms not unlike conventional plastic products, and some manufacturers claim its useful range to be as low as −60°C and as high as +200°C (the magnetic iron-oxide material presents a problem only at about +400°C when it reverts to nonmagnetic form).

As might be expected, the size and weight of mobile recorders for missiles and aircraft has been ever downward. Completely transistorized systems, lightweight metals, and miniature mechanical components have been used. These techniques have helped, but equipment will have to be shrunk much further.

There no longer appears to be a question of whether the magnetic tape recorder can serve as a useful tool in rocket and missile applications, but rather how it can serve the best.

Engineering and management opportunities in...

RCA SYSTEMS SUPPORT PROJECTS

RCA offers expanding opportunities in Weapon Systems Support projects. This work involves program planning, advanced operations analysis, systems analysis, equipment development and design, and systems integration. Experience is desired in the many areas of systems support—checkout and test equipment, logistics, and training.

Exceptionally fine professional and management positions are available to EE's, ME's, Mathematicians, and Physicists with at least five years of experience.

Salaries are excellent; opportunities for advancement, unlimited. Benefits are among the best in the industry. Several current Systems Support Project areas are:

Aircraft electronics systems

Military and civil digital communications systems

Missile systems

Space vehicles and space stations

New Techniques Aid Electronics Cooling

Basic methods of heat dissipation in components are the same but the applications can vary. Here are the principal cooling methods.

by Hal Gettings and Charles D. LaFond

WASHINGTON—Electronic components cooling is a part of equipment overall cooling design that must complement the system or it might just as well be eliminated. Where system cooling transfers heat to the ultimate sink, components cooling transfers unwanted heat in such a manner that it can be picked up by the greater heat exchange mechanism.

Basic methods of heat dissipation are the same—only the applications vary:

- Cold plate mounting (air, liquid or evaporative)
- Direct forced air convection
- Free convection to ambient air
- Radiation heat transfer

Other methods, such as direct liquid cooling, could be used but these are the most commonly encountered.

• **Cold plate cooling**—A common and often quite satisfactory method of cooling electronic equipment is by conduction or cold plate cooling. In a recent paper by Mr. J. R. Baum, a senior staff member of the **Motorola, Inc.**, Mechanical Engineering Laboratory at Phoenix, Ariz., the application of cold plate cooling to an airborne radar receiver/transmitter was described. It was emphasized, however, that the design method provided the same general approach employed in all cold plate cooling of electronic equipment.

The method was chosen in this instance for several reasons. Pressurization of the unit for electrical reasons was a requirement. The most severe temperature—altitude requirement established for the equipment was 131°F at 10,000 feet. The equipment had a total power dissipation of 430 watts and was designed for operation in ambient temperatures up to 131°F for continuous operation and 160°F for short periods of time.

It was estimated that if no cooling provisions were made in the equipment design the unit would have at least a 100°F rise over the ambient temperature in the external surface. In addition, the maximum electronic component temperature rating was 185°F. Because of pressurization, direct forced-air cooling through the equipment could not be used.

To support the cold plate conduction cooling, forced air was to be employed for cooling the component mounting structure. This was accomplished by employing a split casing mounting bulkhead. This was installed horizontally and separated to provide the space through which ambient air could be forced by means of small external blowers. To better utilize available space and for better air distribution two small blowers were employed rather than one large unit. To increase the efficiency, a series of fins parallel to the air flow were used to provide maximum heat transfer.

• **Forced air convection**—The term "forced air convection," usually refers to the use of blowers or externally supplied cooling air for circulation within the electronic equipment. Thus a source of moving air is available for cooling, but without the refinements of cold-plate construction.

Air velocity over a dissipator can be increased by the use of baffles or ducting to direct and increase the local velocity of the available air over the desired area. A short dimension in the flow direction is desirable and this may dictate the baffle orientation.

Where no central forced air circulation exists, it may still be necessary to provide for high rates of local heat dissipation by use of small blowers. A number of miniature blowers are available to meet a variety of situations. The choice would be based on the required velocity, space, and other requirements.

• **Free convection**—Probably the most common method of getting rid of heat in electronic equipment is by free convection. Where components are mounted on metal chassis of larg area, in room ambients, usually no ser ous problem exists. With higher am bients and denser packaging, the prob lem can become acute.

One common decision to be mad in orientation of the dissipator i whether it should be mounted hor zontally or vertically.

In general, Motorola has foun that vertical surfaces with the shor dimension vertical are the most de sirable. A series of short vertical fin very close to the component i effective. This configuration also min mizes the distance from the componen to the dissipator and reduces th accompanying internal thermal resist ance of the dissipator. Because of th extremely low value of convection hea transfer, there is a need for providin maximum dissipating area and mini mizing thermal resistance up to the dis sipating area.

• **Radiation heat transfer**—Radia tion heat transfer is important with fre convection, since it can be of the sam order of magnitude as the convectio term. In considering radiation hea transfer, emissivity and shape factor are the only terms capable of being in creased.

The shape factor is fixed by th overall orientation of the dissipato with respect to its surroundings. Thi is a function of the particular con figuration and cannot be easily altered

The emissivity factor is a direc function of the finish, or radiatin "color," of the dissipator and the re ceiving surfaces. A highly emissive finish such as flat black is desirable Surface finish is one factor often over looked where the heat transfer can b increased with practically no effort. T attain the best possible surface fo radiation, a high emissivity surfac should be provided on both the dissi pator and receiving surfaces.

• **Electron tube cooling**—Majo cause of failure with miniature electron tubes, revealed by exhaustive investiga

ions by many manufacturers and the government, is excessive operating temperatures. To reduce this failure cause, a number of cooling methods have been utilized.

Where component density is not a problem, an airflow directly over the tubes has been successful.

In high-density packages adequate cooling is a great problem. In addition, the metal tube shield used for electrical shielding tends to add to the problem.

Motorola has determined after extensive testing that the use of heat dissipating shields and inserts can help to minimize this difficulty. A substantial improvement in thermal performance results. Also, the investigation showed that horizontal types were considerably more efficient than vertical types.

The most common method of utilizing these tube heat dissipators is to employ some form of clip, shield, or mount to grip the tube envelope. This provides a means of conducting heat to the chassis, cold plate, etc.

• **Power transistor cooling**—Generated at the collector, heat in a power transistor must be transferred to the ultimate sink through a thermal path between the sink and junction. Thus it behooves the design engineer to understand the limits of various mounting methods.

The design of most power transistors provides for the best possible internal thermal path between junction and base. Also, the base is provided with sufficient area for proper heat transfer to the dissipating device.

Of the various methods of heat transfer, cold plate cooling offers the fewest problems in transistor mounting. If the transistor is mounted without an electrical insulator, only the bare surface contact resistance is present. Addition of an electrical insulator such as mica or Mylar will further increase the resistance to heat transfer.

For various insulators, the contact resistance is the governing factor rather than the insulator thickness. In general, the mating surfaces should be as smooth as possible with maximum contact pressure. Minimum insulator thickness should be used, consistent with electrical requirements. If possible, a conductive grease should be applied in the joint. The use of a surface-treated thin metal washer, such as anodized aluminum, appears to have some merit.

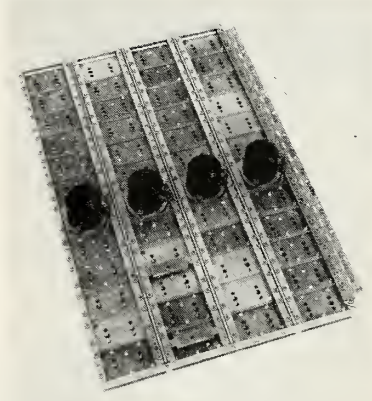
The use of a highly thermal-conductive material is the best method of assuring efficient dissipator performance. Consistent with weight and space requirements, a large enough cross-sectional area should be used to increase conductance. When weight limitations are involved, thermal conductivity and material density must be considered together. On this basis, it has been found that for the same weight the conductivity of magnesium and aluminum are superior, in that order, to copper. This is true in spite of the fact that magnesium and aluminum have a lower thermal conductivity than copper. Where space alone is a consideration, then thermal conductivity will govern.

The distance between the transistor base and the midpoint, or average temperature point, of the dissipator should be kept to a minimum consistent with the thermal conductivity and thickness. This particular point must be considered, together with the necessity for having sufficient dissipator surface area. For example, if an increase in horizontal dissipator area is required in a particular case, then the thickness or material conductivity must be increased proportionally. Failure to do this can increase the resistance to heat transfer in the dissipator at the same rate that heat transfer from it is being increased —with no net gain.

One approach to this problem is to provide a dissipator configuration (such as vertical finning) so that the distance between base and average temperature point may be kept short with no loss in area.

In some cases the designer can choose the method of dissipating the heat to the ultimate sink. If this is the situation, the selection of dissipator and cooling methods go hand in hand. It is assumed that the dissipator provides the conductive link to the final method of dissipation to a sink. So-called conduction cooling still requires final dissipation to the ambient air or to a coolant fluid at some point.

• **Miniaturized IR cooler—Arthur D. Little, Inc.,** of Cambridge, Mass., has developed a tiny cooling device which super-chills infrared detection equipment to 60° Kelvin (−350°F). It employs a new refrigerating technique which may prove to be a significant scientific achievement.



The eight-ounce min-IR cooler resulted from a two-year research project into extreme low temperature equipment conducted by Dr. Howard O. McMahon and William E. Gifford at Arthur D. Little, Inc. Cambridge research and engineering company. It was unveiled at the 1959 National Missile Industry Conference in Washington, D.C.

Development of the system for infrared applications is being conducted by ADL and **Hamilton Standard, Division of United Aircraft Corp.,** Windsor Locks, Conn.

The heart of the system is the cooling head which is inserted into or preferably made integral with the IR cell dewar. System operation is based on regenerative precooling of

THIS Arthur D. Little-developed min-IR-cooler is a low-pressure, closed-cycle refrigeration device developed for use with IR detection equipment.

THIS environmental conditioning system by AiResearch utilizes a series of modules to serve as a cold plate.

WEIGHING two pounds, this Dunham-Bush ethylene glycol-to-air heat exchanger has capacity of 5460 BTU/hr (1600 watts).

wider range response . . .

relatively low pressure gas and performance of work by the gas during expansion.

The closed system consists only of a compressor and the cooling head. The cooling head contains inlet and exhaust valves, expansion piston, regenerator, and cylinder.

In operation, helium gas expands from 300 psi in a ¼" diameter cylinder, 2" long. A tiny plastic piston is the only moving part of the unit below room temperature. The cold end of the tube refrigerates an infrared cell to 60° Kelvin. (Cooling infrared detectors to extremely low temperatures increases their sensitivity and makes them responsive to a wider range of IR wave lengths.)

Since gas cooling is achieved through an expansion work cycle and not through the Joule-Thomson effect, porous plug clogging difficulties are eliminated and maximum system pressure (and thus component size and weight) is greatly reduced. Hamilton has stated that the closed system presents no limitations on stand-by or service operative periods and is logistically simple.

This device is considered to be the first satisfactory miniature refrigerator for extremely low temperatures.

The same principles used in the min-IR-cooler are being applied by ADL to other areas of low temperature.

• **Peltier cooling**—The practicality of applying Peltier cooling to a telemetry package has been shown by Ray Marlow of **Texas Instruments, Inc.,** in a paper presented at the American Rocket Society's Semi-Annual Meeting in San Diego in June.

To optimize performance in a missile-borne telemetry system, components must be protected against extreme or sudden temperature variance. The operating characteristics of transistors and diodes are particularly influenced by operating temperatures.

If the package is provided with thermal insulation, heat build-up resulting within the system must be controlled by some means of disposal. This is particularly true in a satellite having a long flight time. Also, during long pre-flight checkout operation of missiles, this problem is manifest.

Marlow suggests that here Peltie cooling and heating appears to offer solution in airborne or missile elec tronic equipment.

The Peltier effect is achieve through the direct conversion of elec trical energy to thermal energy by pass ing an electrical current through tw semiconductors in series. One junctio of the thermoelectric element become cold and the other hot, depending o the direction of the current. The col or hot junction will provide an environ ment in which the electrical compo nents will operate with increased reli ability in a telemetry package.

The great advances in semiconduc tor materials in the past years hav permitted improved performance o the Peltier effect. The use of thi method of component cooling coul provide a thermal environment tha would lengthen component life expec tancy. Reliability is inherently hig since there are no moving parts in volved.

Marlow indicated that the limitin factor of Peltier cooling is the materia itself used to make the thermoelectri thermo-elements. But, he believes th use of Peltier cooling and heating wil increase with the advance of the state-of-the-art in semiconductor materia fabrication.

propulsion engineering

By M/R STAFF

Solar sail propulsion. . .
will be a reality "fairly soon." T. C. Tsu, advisory engineer, mechanics department, **Westinghouse Research Laboratories,** believes that a solar sailing project can be "realized fairly soon without extensive research and development." He discusses the characteristics and advantages of "Interplanetary Travel by Solar Sail" in the American Rocket Society Journal, June. Tsu presents solutions to the equations of motion and optimization of sail tilt angle. He also computes travel time and general performance compared with chemical and ionic propulsion.

Think of a solar sail vehicle . . .
as a rocket with unit mass ratio and an infinite propellant reserve, says Tsu. He refers to R. L. Garwin's paper, "Solar Sailing—a Practical Method of Propulsion within the Solar System," Jet Propulsion (ARS Journal), March 1958, for figures on cost and feasibility. "The solar sail is of negligible cost," Tsu summarizes, "and is perhaps more powerful and less difficult than many often-cited and competing schemes." A solar sail operates by the pressure of sunlight falling on a sail made of ultra-thin aluminum foil or aluminized or silvered plastic sheet. This is the radiation pressure principle, known to physicists and parlor trick fans for many years.

Advantages of solar sails are numerous . . .
The ship's mass remains constant; sail force is available for the ship's entire journey; neither fuel nor other propellant is needed; no powerplant is needed, and consequently there are no waste heat disposal problems. Although the force is very small compared with that available from chemical rockets, Tsu points out that the force is available for as long as it is needed.

"A trip to Mars or Venus can be made . . .
in less time by solar sail than by chemical rocket," says the Westinghouse engineer. A solar sail can return to earth or make in-flight navigational corrections whenever necessary. Since it moves at a non-uniform speed under a non-central force system, the sail's contents are not entirely weightless. However, the weight of a load would be much less than on earth.

New oxidizer data handbooks . . .
are available from a leading manufacturer of rocket propellant oxidizers, **Allied Chemical's** General Chemical Division (40 Rector St., N.Y.C. 6). Allied offers a 29-page bulletin on fuming nitric acid, both white and red, properties, corrosion data, storage and handling directions. The company also offers a bulletin on both gaseous and liquid fluorine, and a work on chlorine trifluoride, which also includes data on the other halogen fluorides. These data booklets supplement the existing Allied library on oxidizers: Handling elemental fluorine gas in the laboratory, liquid fluorine unloading procedure, chlorine trifluoride vapor pressures.

USSR is bragging about chemical progress . . .
made since the Communist Party central committee meeting a year ago last May. That was the meeting at which Russia decided to accelerate chemical industry development, especially production of synthetics. The Soviet Embassy (Washington) says the industry has "overfulfilled the 1958 plan for gross output." Production was 13% over 1957 production, and the first five months of 1959 show production up 11% over 1958, the embassy statement says. Included among the items cited, are jet engine compressor blades.

Alcohol from crude oil . . .
is up, the Russians say. Last year, the USSR produced 26 million decaliters of alcohol from crude oil. Although the Embassy release does not spell it out, there is a strong hint that the majority of Russia's alcohol in the past had been produced by the fermentation process.

Sonic Burning Control Sought for Solids

Resonance burning, a phenomenon that has bothered rocket engineers for years, may be put to good use. **Acoustica Associates Inc.** of Plainview, N.Y., says it has received a $85,188 contract from NASA to study the possibility of controlling the burning rate of solid rockets through high-intensity, ultra-high-pitch sounds.

David Gross, an Acoustica engineer, said a threshold effect indicates that the control might become operative at a pitch upwards of 10,000 cycles a second. This is a just barely audible note than can be produced on a violin but is about 1½ octaves above the highest note on a piano. The human car is sensitive to pitch up to about 15,000 cycles.

Gross said research by the Russian T. M. Kurbansky and Americans at Georgia Tech seems to show that the burning rate of typical solid propellants can be increased 3 to 10 times by such sonic mixing. At present, the only control available for solid rockets is the on-off type.

Acoustica is a developer of ultrasonic sound equipment used for industrial cleaning and liquid gauging.

ABMA technicians have come up with their own version of "rock and roll." This shake table can put 30,000 pounds through a rotary action providing up to 90,000 pounds gross vibrating force. The facility is about 10 ft. in width and can accommodate vehicles with wheel bases up to 50 ft.

New Regulations Up On Operational Status

New regulations now in the process of coordination by Air Force headquarters will give major weapon system management responsibility to the Deputy Chief of Staff (Operations). Under the new rules, "general operational requirements" will be abandoned in favor of "required operational capability documents" which will be the responsibility of Deputy Chief of Staff (operations).

Since there is still a necessity to evaluate the technical requirements of proposed weapon systems, Deputy Chief of Staff (Development) will issue "system development requirement (SDR)" and subsystem development requirement.

After that it will be up to the Deputy Chief of Staff (Operations) to determine the feasibility of producing a new weapon system, after first determining that the proposal meets both the required operational capability and the system development requirement. At this point, he will order a new system into production by issuing a new "Specific Operational Requirement" and "Operational Support Requirement" document.

By this new method, AF hopes to establish tighter AF management control over new weapon systems. However, official statement indicates that there will be no change in procurement practices.

E-B Gets Contract

Electric Boat Division of General Dynamics Corp. has been given a contract to build the aiming system for the nation's largest radio telescope being constructed by the National Radio Astronomy Observatory in Greenbank, W.Va.

Aerojet-Stauffer Make Alloys

Development of a "new family" of metals for solid rocket casings has been achieved by **Aerojet-General Corp.** and **Stauffer-Temescal Co.** of Richmond, Calif., M/R has learned. The new alloys, of tantalum and tungsten, can be produced cheaply, machined normally, and still withstand the tremendous heat of solid rocket motors.

Aside for the rare metal rhenium, the two components of the new alloys have the highest melting points of any known metal. The joint-effort program carried out by Aerojet and Stauffer-Temescal has produced ingots measuring 5" in diameter and 42" long, from the electron-beam furnaces at Stauffer-Temescal.

The alloys have a melting point which falls between 5430 and 6150 degrees F. The melting points of pure tantalum and tungsten. The tensile strength of the worked 90% tantalum, 10% tungsten alloy at room temperature is 150,000 psi, and at 4500° F. the strength is still about 15,000 psi.

The tantalum/tungsten alloys are very resistant to chemical attacks because of the extreme purity imparted to the alloys during electronic-beam melting. The ingots are worked and fabricated using conventional steel-mill equipment and methods, and are machined by Standard Machine Tools.

Direct re-cycling of scrap has reduced costs of the finished shapes of the alloys. The development program was headed by J. A. Griswold and C. L. D'ooge, project engineers in Aerojet's program of developing solid-fueled propulsion for *Polaris* FBM. Stauffer-Temescal Company is owned by Stauffer Chemical Co. and Temescal Metallurgical Corp.

Centaur Guidance To Be Pure Inertial

Minneapolis-Honeywell has won a $5.4 million contract from **Convair** to develop and produce a pure inertial guidance system for NASA's *Centaur* space vehicle. System will incorporate a variation of Honeywell's "mig" (miniature integrating gyro) that must be capable of putting either 9000 pound payload in 300-mile orbit or "soft" land 1000 pounds on the moon.

One of the companies now engaged in DOD's GLIPAR (Guide Line Identification program for Anti-Missile Research) program is **Technical Operations Inc.**, which has $127,000 contract to develop any "unorthodox" long-term anti-missile approaches. Program is studying everything from "death rays" to anti-gravity devices.

New milling technique utilizing chemicals—but different from conventional chemical milling processes—is disclosed by United States **Chemical Milling Corp.** The company says tolerances of sheet metal can be improved through its "Chem-Tol" method so that the variation of metal thickness is less than ±0.001 inches.

15 *Delta* Engines

Multi-million dollar contract for 15 liquid powered engines for NASA's *Delta* deep space mission rocket has been awarded **Aerojet-General Corp.** by **Douglas Aircraft Co.** Deliveries of the second-stage engines will extend over a two-year period and will be similar to those used in *Vanguard* and *Thor-Able* program. Aerojet says while associated with these programs this particular engine has had a perfect record of nine for nine to date.

NASA is buying 20 modified Navy pressurized flight suits for $75,000 from **B. F. Goodrich Co.** for its *Mercury* astronauts. Evaluation team members wore the suits for as long as 24 hours before the selection was made.

Standard Tests Methods For Relays Proposed

The American Standards Association has virtually completed a proposed industry-wide code establishing standard test methods for relays. The code, first ever to be drafted by industry, will be circulated for comment and approval following a review meeting in New York in September.

Hazeltine Acquires Wheeler Laboratories

Hazeltine Corp. of Little Neck, N.Y. has acquired **Wheeler Laboratories, Inc.**, in a move to double its engineering department. The Laboratories now are wholly-owned subsidiary of Hazeltine.

Wheeler Laboratories' experience has been in microwave, antenna and related fields in the *Nike-Ajax, Nike-Hercules, Titan, Thor, Nike-Zeus* and *Terrier-Tartar* projects.

Hazeltine recently established a test and engineering center in Indianapolis and started construction of an engineering laboratory in Greenlawn, N.Y.

contracts

MISCELLANEOUS

$324,000—Consolidated Systems Corp., Subsidiary of Consolidated Electro-dynamics Corp., Monrovia, Calif., for an automatic data recording and monitoring system to be installed at Thermo Structures Laboratory at Sunnyvale, Calif. (Subcontract from **Lockheed Aircraft Corp.**).

NASA

Aerojet-General Corp., has received "multi-million" dollar contract for the production of 15 liquid powered engines similar to those used in *Vanguard* and *Thor-Able* programs for use in varied NASA space experiments.

$100,000—Applied Science Corp., Princeton N.J., for airborne statistical telemetering equipment for project *Mercury* capsules. (Subcontract from **McDonnell Aircraft Corp.**).

NAVY

$3,500,000—Reaction Motors Div. of Thiokol Chemical Corp., Bristol, Pa., for production of the *Guardian II* pre-packaged rocket engine.

$2,000,000—Pratt & Whitney Aircraft Div. of United Aircraft Corp., East Hartford, Conn., for development of nuclear aircraft engine hardware.

$1,921,672—Convair Div. of General Dynamics Corp., Pomona, Calif., for *Terrier-Tartar* shipping containers and handling bands.

$100,332—Aerojet-General Corp., Sacramento, Calif., for 5KS-4500 X112A rocket engines (reloads) and 5KS-4500 X112A3 rocket engines (new).

AIR FORCE

Scaife Company, Oakmont, Pa., has received a contract for additional *Falcon* missile motor cases, bringing the current orders on this item to almost $400,000. (Subcontract from **Thiokol Chemical Corp.**).

$3,596,026—Gas Industries, Inc., Allentown, Pa., for oxygen, nitrogen. (three contracts).

$875,000—Summers Gyroscope Co., Santa Monica, Calif., for spare parts on the Phase II Vertical Gyro Indicator.

$740,250—Lewyt Mfg. Corp., L.I. City, N.Y. for coordinate data monitor.

$299,906—Melpar, Inc., Falls Church, Va. for weather data record viewer, spare parts, and special test equipment and applicable data (ground support equipment).

$234,646—Stanford Research Institute, Menlo Park, Calif., for design and construction of parabolic antennas.

$117,208—Union Carbide Corp., Linde Co. Indianapolis, for liquid oxygen converters and engineering and maintenance data.

$105,169—Thompson Ramo Wooldridge, Inc., Cleveland, for nuclear regenerative fuel cells.

$97,350—Plasmadyne Corp., Santa Ana, Calif., for investigation of the production of millimeter and sub-millimeter electro-magnetic waves.

$95,985—Convair Div. of General Dynamics Corp., San Diego, for spare parts for center missile bay door equipment assembly.

$88,823—Barnes Engineering Co., Stamford, Conn., for radiation measurements from major missiles.

$88,748—American Institute for Research, Pittsburgh, for development of optimum methods of organizing and presenting SAGE operator job information in semi-training equipment.

$74,739—Schulz Tool & Mfg. Co., San Gabriel, Calif., for operational development of nozzles and adapters for pressure serving advanced missiles and aircraft.

$73,677—Parker Aircraft Co., Los Angeles, for operational development of missile propellant servicing couplings for use on advanced missiles and aircraft.

$68,326—Stanford Research Institute, Menlo Park, Calif., for research directed toward the use of satellite radiation observations in numerical weather prediction techniques.

$56,414—General Communication Co., Boston, Mass., for radar beacons.

$51,948—Elkton Div., Thiokol Chemical Corp., Elkton, Md., for *Cajun* rockets.

$49,626—Aerolab Development Co., Pasadena, Calif., for component parts of the *Nike-Cajun* rocket system.

$39,935—Lowell Observatory, Flagstaff, Ariz., for research directed toward the study of the property of the planets.

$34,982—North American Aviation, Missile Div., Downy, Calif., for research directed toward study of geophysics of the moon.

$34,531—Regents of the New Mexico College of Agriculture and Mechanic Arts State College, N. Mex., for rocket instrumentation engineering services.

ARMY

Aerojet-General Corp., Azusa, Calif., has been named the prime contractor for the design of a six-million-pound-thrust rocket test stand to be constructed at Edwards AFB, Calif. (Amount not disclosed.)

$14,320,690—Sperry Rand Corp., Sperry Utah Eng. Lab., Salt Lake City, for *Sergeant* missiles.

$5,347,428—Convair, Div. of General Dynamics Corp., Pomona, Calif., for feasibility study. (Two contracts).

$3,569,388—Douglas Aircraft Co., Santa Monica, Calif., for repair parts, launching equipment and missile technical representative services. (Three contracts).

$2,000,000—Aerojet-General Corp., Downey, Calif., for further flight testing of two SD-2 Drone systems including design improvements and manufacture of AN/USD-2 surveillance drones.

$1,973,000—California Institute of Technology, Pasadena, Calif., for research and development. (Two contracts).

$1,504,250—Western Electric Co., Inc., N.Y., for development of production equipment for the mechanized production of semi-conductor devices for the *Nike-Zeus* program.

$924,717—Cubic Corporation, San Diego, Calif., for electronic measuring system.

$390,582—General Electric Co., Cincinnati, for fabrication, static and wind tunnel testing of tip turbine, liftfan propulsion system and design and fabrication of wind tunnel model.

$373,269—North American Aviation, Inc., Canoga Park, Calif., for design and development.

$356,265—Paul Smith Construction Co., Orlando, Fla., for construction of G/M launch facilities.

$306,775—Consolidated Systems Corp., Monrovia, Calif., for digital acquisition system.

$274,015—Radioplane Co., Div. of Northrop Corp., Van Nuys, Calif., for supplies and services re missile targets.

$234,614—Aerojet-General Corp., Azusa, Calif., for warhead.

$221,858—Biltmore Construction Co., Clearwater, Fla., for construction of FPS-26 radar tower and facilities at MacDill AFB, Tampa, Fla.

$215,816—Domestic Film Products Corp., Millersburg, Ohio, for air supported tents for *Nike-Hercules*.

$195,114—RCA, Moorestown, N.J., for research and experimental work in connection with radar parameter measurement and improved operation of instrumentation radar sets.

$190,391—U.S. Amalgamated Constructors, Inc., Tampa, Fla., for construction of flight simulator training building at MacDill AFB.

$189,000—Electro Plastic Fabrics, Pulaski, Va., for air supported tents for *Nike-Hercules*.

$187,900—Irving Air Chute Co., Inc., Lexington, Ky., for air supported tents for *Nike-Hercules*.

$179,529—The Berger Bros. Co., New Haven, Conn., for air supported tents for *Nike-Hercules*.

$154,927—Motorola, Inc., Scottsdale, Ariz., for telemetry sets.

$110,250—Bomac Laboratories, Inc., Beverly, Mass., for electron tubes.

$99,431—Aeronutronic Systems, Inc., Glendale, Calif., for study ground effects air-cushion vehicle.

$99,428—General Electric Co., Syracuse, for research and development work to perform modes of failure and reliability prediction studies of pulse cables.

$86,050—Radio Corp. of America, Harrison, N. J., for electron tubes.

$82,583—Raytheon Co., Waltham, Mass., for electron tubes.

$80,635—Tung-Sol Electric, Inc., Newark, N.J., for electron tubes.

$68,598—Aerojet-General Corp., Azusa, Calif., for analysis of fuel developments and rocket engine designs.

$66,776—Minneapolis Honeywell Regulator Co., N. Hopkins, Minn., for *Honest John* adaption kit components.

$60,000—Unit Research, Inc., Cambridge, Mass., for study of wind shear measurements.

$48,103—Bridgeport Brass Co., Hunter-Douglas Div., Riverside, Calif., for redesign of rocket and launcher.

$45,750—Wallace O. Leonard, Inc., Pasadena, Calif., for transducers.

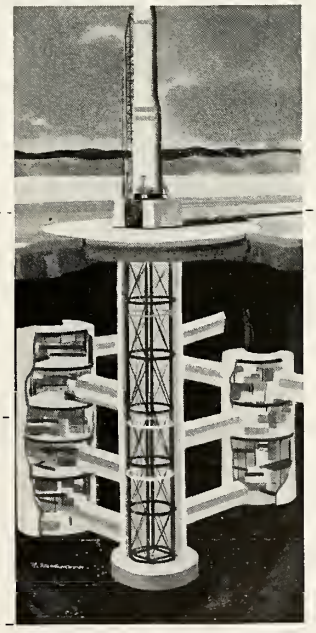
$44,990—North American Aviation, Inc., Missile Div., Downey, Calif., for study of satellite rendezvous.

$44,800—Firestone Tire and Rubber Co., Los Angeles, for guided missile.

$30,800—Firestone Tire and Rubber Co., Los Angeles, for guided missile.

BIDS

Purchasing and Contracting Div., White Sands Missile Range, N. Mex., ORDBS-P&C-A: Mounts for camera, single precision axis, capable of supporting cameras up to 300 lbs. Contractor shall furnish all labor and material in construction of the mount—9 ea.—IFB-ORD-29-040-60-34—Bid opening 16 Aug. 1959. Bid sets available through 16 Aug. '59.



Dayton Air Force Depot, Gentile Air Force Station, Dayton, Ohio. Att: Directorate of Procurement and Production:
Tube electron Klystron type 6BM6A in A/W Spec MIL-E-1D, dated 31 Mar. 58 and ISS MIL-E-1/746C dated 30 Nov 56 S/N 5960-355-7269—3000 ea.—IFB 33-604-60-131B—Bid opening 7 Sept. 59.
Capacitors fixed and variable identified by manufacturers part numbers, 24 items—various quantities—IFB 33-604-60-121B—Bid opening 7 Sept. 59.
Tube electron transmitting RETMA type 673 S/N 5960-669-6864, 275 ea. Tube electron planar triode type 6280/416B in A/W MIL-E1/366A (Navy) Except that qualification approval is not required S/N 5960-NSL, 3400 ea.—IFB 33-604-60-8B—Bid opening 12 Aug. 59.

U.S. Army Engineer District, Norfolk, Ft. of Front St., Norfolk, Va. Construction of Langley *Bomarc* facilities, flight "B" Langley AFB, (A) Twenty-eight launcher storage buildings on piling: Buildings are about 62'x23' with structural steel framing and combination of metal and precast concrete panel siding. These buildings have a sliding roof and required mechanism to open them in a short time. (B) Composite building: Metal building about 160'x160' on piling; (C) Electrical distribution and communication systems; (D) Distribution systems for hot water, low pressure compressed air; (E) Water distribution system; (F) Roads and hardstands; (G) Chain link fencing (2150' plus or minus); (H) Site prep. grading and seeding; (I) storm drainage system.—IFB ENG-44-110-60-1—Bid opening 28 Aug. 59.

1939
Ets-Hokin and Galvan installed "Mousetrap" rocket launchers on U.S. Navy sub-chasers.

1956
EHG pioneered in the installation of electronic systems of test and launching complexes for Intercontinental Ballistic Missiles.

1959
EHG has now installed or serviced the electrical and electronic phases on most of the ICBM complexes in the United States.

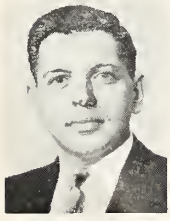
Burt Ramsay, chief engineer, technical, has been named director of Engineering, Amelco, Inc. with **Roger R. Boy de la Tour,** assistant chief engineer, technical, succeeding Ramsay at the electronics firm. Ramsay joined Amelco two years ago after leaving the Canoga Corp. where he worked on development of various missile support systems, solid state amplifiers and power supplies. Boy de la Tour came to Amelco in December 1958 from Lear, Inc.



David A. Young, who was Aerojet-General's first employee when the company was founded in 1942, and recently chief of ARPA's space technology program, has been named director of Corporate Long Range Planning Division by Aerojet. Young, a graduate of CalTech, served in various positions at Aerojet, including chief of the Rocket Physics Department of the Research Division and assistant chief engineer of the Liquid Engine Division in charge of nuclear projects.

Charles C. Goodrich, as Douglas Aircraft Co.'s representative at the Army's Redstone Arsenal, will operate from a new Douglas office to be established in Huntsville, Ala. He will maintain technical liaison with the Army Ordnance Missile Command and the Army Guided Missile Agency. Goodrich has been at White Sands Missile Range for the past five years and, since last fall, has been project engineer for the *Nike* series at that location.

Dr. Leonard S. Sheingold of Sylvania Electronic Systems, division of Sylvania Electric Products Inc., has been named a member of the U.S. Air Force Scientific Advisory Board. Dr. Sheingold, who is manager of Sylvania Electronics' Applied Research Laboratory, has held many active and advisory appointments to governmental scientific groups including DOD's Weapons Systems Evaluation Group, the Operations Research Office of Johns Hopkins University and the Office of Naval Research.

Russell A. Kimes, director of American Machine & Foundry Co.'s General Engineering Laboratories, has been appointed a divisional vice president of AMF's Government Products group. He will also continue as director of engineering, responsible for the operation of AMF's Alexandria division in Alexandria, Va., the Greenwich Engineering division, and the Mechanics Research division in Chicago. He will work out of G.E.L. headquarters at Greenwich, Conn. Kimes came to AMF in 1946 as assistant works manager of the Buffalo plant.

Fred Rauschenbach, former sales manager of Martin-Baltimore, has joined United Electro Dynamics, Inc. as manager of Development Planning in charge of company expansion and market development. Rauschenbach, whose 16 years in the Marine Corps includes work in guided missile development, was later assistant project engineer on the *Lacrosse* missile for Martin-Baltimore and also spent a year with ACF Industries, Avion Division, directing the weapons systems department.

Dr. John M. Salzer has joined the technical staff of the vice president, Engineering, Ramo-Wooldridge Division of Thompson Ramo Wooldridge Inc. Formerly director of systems at the Magnavox Research Laboratory, Dr. Salzer worked in systems investigations, promotion of military products, supervision of projects in missile guidance, control computers, data processing, communications systems, and special studies. Prior to that he was with Hughes Aircraft Co.

David I. Margolis, former assistant treasurer of the Raytheon Manufacturing Co., has been named assistant to the president of International Telephone and Telegraph Corp. From 1952 to 1956 he was security analyst for Josephthal & Co. of New York City. Three engineers have been promoted to senior scientists at ITT Laboratories, Nutley, N.J.: **Richard E. Gray,** former senior project engineer c the Radio Communication Laboratory and **Henry F. Herbig** and **Malcolm C Vosburgh,** former executive engineers c the Wire Communication and the Avioni Systems Laboratories. They will work o development and application of ne scientific theories and laws.

Dr. Ray P. Dinsmore, authority o natural and syn thetic rubber an vice president c research and deve opment for th Goodyear Tire Rubber Co., ol served his 45th yea with the firm re cently. Dr. Din more's colorful ca reer in research ha been highlighted by award of the Colwy Gold Metal for 1947, awarded by the In stitution of the Rubber Industry for h work in synthetic rubber research and i development and application to product and the Charles Goodyear Medal for 195 by the Rubber Division of the America Chemical Society.

Appointment of **Julian J. Kliolz,** vic president, to serv on the board of d rectors, was an nounced by Asso ciated Gaskets, In Other appointmen by the firm: **Josep J. Locastra,** pla superintendent an **Paul Gordon Am brose,** productio manager. Kliolz b came a vice president in 1948 when h came to the firm from the H. O. Canfie Rubber Co., where he was assistant pr duction manager. Locastra also came fro Canfield, starting there in 1923 and worl ing in almost every department of th organization. Ambrose has been assista production manager at Associated Gaske since 1957.

Robert E. Lehman has been appointe manufacturing ma ager of Pulse E gineering, Inc., ele tronics firm, aft 12 years at Lenku Electric, where h was variously tran former productio foreman, transfor er design enginee manager of th transformer desi group, and manager of the transform standards group.

letters

Quality Important

To the Editor:

We have read with interest the excellent article, "Notch Sensitivity Will Crack," which appeared in the June 2 issue, page 15. The article, however, makes little mention of the importance of the quality of the basic materials used in rocket cases.

While **Allegheny Ludlum's** role has been as a basic supplier of special cleanness air melt and more importantly, consutrode vacuum melt plate, sheet, and forging billets, and we have not entered into the fabrication or testing of completed casings, it is our understanding that there is increasing verification that the cleanliness and freedom from even minute internal flaws is extremely important in insuring maximum bursting strengths. We are also informed by our customers that the high-strength, low-alloy grades melted to extreme cleanliness standards and consutrode vacuum melted to very low inclusion counts offer considerable advantage in the ability to form such materials in the severe spinning operations involved in certain designs.

J. B. Henry
Manager, High Temperature
Alloys & Valve Steels
Allegheny Ludlum Steel Corp.

We will deal with this in future articles.

Overindulged?

To the Editor:

Your editorial, "Wake Up and Live," in the June 22 issue was a superb summary of what has happend in the aircraft industry to cause the current rash of symptoms. It's like the man who has eaten the best rich food for years—and now has the gout.

Keep up the good work. It takes guts to tramp on people's toes, but it is necessary and good at times.

Larry L. Booda
CDR, U.S.N.R.
Navy Department
Washington 25, D.C.

Clarification Pleases

To the Editor:

"New England's Missile Boom," by William E. Howard, in the July 6 issue of M/R, was another fine article that helps clarify this thing called the "missile industry . . ."

W. E. Green
Metal Fabricators Corporation
73 Pond Street
Waltham 54, Mass.

New Missile 'Bible'

To the Editor:

Your superb July 20 issue—the Third Annual Engineering Progress Issue and World Guided Missile Encyclopedia . . . will forthwith become our "bible" as we continue to work with manufacturers of missile and rocket components . . . You and your staff are to be congratulated on a major contribution to the dissemination of knowledge in this field.

D. J. Duffin
Duffin-Hughes Associates
Public Relations
1518 Walnut Street
Philadelphia 2, Pa.

Congrats on Editorial

To the Editor:

May I be permitted to compliment you on your outstanding editorial in the July 13 issue of MISSILES AND ROCKETS, of which I am a subscriber, headed "Components Reliability: What's Needed?"

Perhaps I am so keenly enthusiastic about your editorial for the reason that I have sung the same song for many, many years—frankly, without too much in the way of results. Your editorial provides much needed ammunition for designers in the missile field, to say nothing of highspeed supersonic aircraft.

As a designer of switches and thermal controls, mostly in the aircraft and missile fields, for the past 30 years, I feel that today we know how to make our respective components right, but there never seems enough time to do the job; and if it is approached, our companies who are naturally commercially minded are appalled at the cost of such devices. Generally speaking, they listen politely and agree in principle but very little is done towards authorizing the research and engineering necessary to do the job with a component that simply will not fail.

It is my feeling that if it is necessary to use a three karat diamond to do the job, we certainly should use the diamond for it is most assuredly impossible to compromise on materials or engineering structure where the minute components necessary are all the more needful of the type of work that goes in an ultra-precision timepiece.

I am trying to get together as many articles on this subject as I possibly can to provide a scrapbook of information and I hope influence on others. Therefore, if possible, I would like to receive as many reprints of this marvelous editorial as you could possibly send me. Also if you have any data along these lines; that is, other reprints of a similar nature, I would very much appreciate receiving it.

L. W. Burch
Consulting Engineer
Metals & Controls

Attleboro, Mass.

Omission

To the Editor:

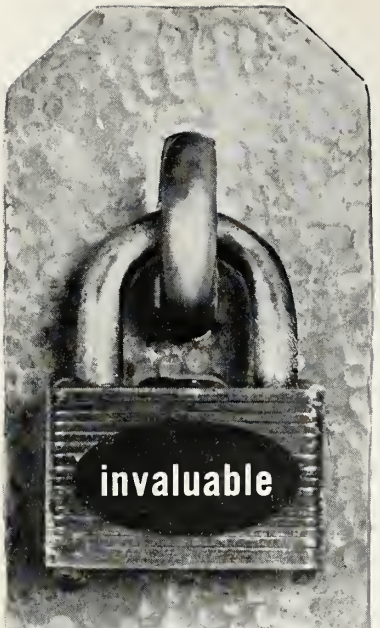
The article, "Boston—'Hub' of space research" by William E. Howard in the July 13 issue fails to note that the "Golden Semicircle" of missile/space manufacturing becomes nearly a full circle when you consider the contribution of General Electric's plant in Lynn, Massachusetts, eight miles northeast of Boston.

Surely, the men who build the accessory power system for the *X-15*, the turbopumps for the *Vanguard* first-stage engine and who are now at work on equipment for future space vehicles, deserve a place on the wheel of the Boston area's space industry.

Paul Schratter
Manager, Product Information
Aircraft Accessory Turbine Dept.
General Electric, West Lynn, Mass.

We regret the omission.

THE MOST!



TO SAY THE LEAST . . .

for high-performance slip rings, brushes,

commutators and switching devices

No one understands the extreme importance and value of vital test film better than CFI. For this very reason, our security system, devised to handle classified film, is the model for the industry.

CFI CAPABILITIES also include the knowledgeable handling of all of your film requirements with the utmost care... for sales and test data films, training films, and visual aids, 16 or 35mm.

CFI's EXPERIENCE with many major aircraft and missile companies and related organizations enable us to recognize the need for uncompromising quality and fast action.

CFI FACILITIES are the finest... complete and modern. Improved processing techniques are constantly being developed at CFI, advancing the state of the art.

CFI KNOW-HOW has been accumulated in its 40 years as the nation's largest and most progressive organization with complete lab facilities in both Hollywood and New York.

COMPLETE INFORMATION is available. Write or call for a representative.

missile business . . .

By WILLIAM E. HOWARD

Very quietly the Small Business Administration is casting a hard look at the "fee" end of DOD cost-plus-fixed-fee research and development contracts. Some strong complaints have been voiced by small firms over DOD policy on fees. They claim the profit margin is too little—in some cases non-existent. The SBA wants to know the extent of the problem; how many small firms are being squeezed out of military R&D competition simply because they can't afford to risk going into the red.

Some small outfits get caught in a jam . . .

They take on R&D projects knowing that they are potential money losers. But they also know that if they don't take them, they will be cutting off their source of work and in the end will have to shut up shop. There is always a chance that a losing proposition may turn into a more lucrative follow-on contract or a bigger related research project. When a company hits a string of losers, however, merger with a big corporation with a strong cash position sometimes becomes the only way out.

The SBA is against the merger trend . . .

now prevalent in the missile industry. The main purpose of this Federal agency is to play mother hen to a brood of small businesses. It wants to see small business thrive—to help little ones grow into big ones.

SBA now is wondering whether DOD is thwarting its mission. M/R has learned that SBA has hired some outside consultants to look into the situation. One problem investigators are up against from the start is finding out precisely what DOD's policy is on fees; who fixes them and why they vary.

Recent Congressional testimony by Perkins McGuire . . .

assistant secretary of defense for supply and logistics, indicates that fees fluctuate rather widely from a token fee of $1 to 10%. A DOD survey shows that the average for all the armed services is somewhere between 6% and 7%. For a small firm working on a $100,000 contract, the fee would run to $6000 or $7000. This doesn't yield much of a profit after taxes and operating overhead are deducted.

Where the SBA inquiry will lead, and what it will turn up, is still a matter of conjecture. But it is a safe bet that any pertinent findings will wind up in the hands of the small business lobby to press for action by either the Administration or Congress.

Historically, Congress has always regarded . . .

anyone who does business with the Government with suspicion. The idea seems to be prevalent that any industry's pockets are automatically lined with gold as soon as the ink dries on a contract. The SBA is going to run into this fixation if it tries to bring about any revision in present policy toward fees.

Why it is perfectly legitimate for a manufacturer to make 15% or all he can in the consumer market, yet practically criminal if he nets more than 2% on a military contract is difficult to understand. Congress has never explored this "double standard" from the viewpoint of how it may affect our research effort and technological progress. And it will be interesting if someone can convince lawmakers that this might be a fruitful field of investigation.

SBA might do well to build a case on the importance . . .

of small company R&D in the missile/defense effort. Contributions from this segment of industry are truely impressive. And there is plenty of evidence to support the thesis that some of the country's best brains function most efficiently when they are in a small company—and when the profit motive is strong.

—when and where—

NASA Budget Cut is Dangerous Economy

If some pollster were to query the 436 members of the House of Representatives with a question which would read like this:

"Do you want the United States to have a space program commensurate to her place in the world of nations and second to no other country on earth?"

The replies undoubtedly would add up to virtually a unanimous "yes."

Why then did the House cut $68 million from the budget of the National Aeronautics and Space Administration early this month before sending it to the Senate? In the words of NASA Administrator T. Keith Glennan:

"During the hearings on our fiscal 1959 budget request, some members of Congress raised serious questions about our not having requested far greater sums than we felt, after careful study, that we needed to organize NASA and initiate the (space) program.

"What has happened since then to give anyone a sense of complacency? For I can only interpret the action of the House as an indication of a lessening in the sense of urgency which has been expressed so often on the floor and in Committee.

"Have we—who started serious work in the space field six or seven years *after* the Soviets were pouring unlimited funds and their best brains into the drive to dominance in space—suddenly achieved some enormous advantage?

"If so, I would like to know about it. I would sleep better at night."

NASA is requesting a fiscal 1960 budget of $485,300,000. In addition NASA has requested $45,000,000 in supplementary funds for 1959.

The House Committee on Appropriations cut the combined requests by $45.5 million.

The House itself, on points of order, further reduced both requests by $22,725,000—a reduction of $68,225,000 in all.

What could these cuts mean to NASA? In the words of the administrator and his qualified associates:

Vega—drastically cut back. *Vega* is a modified three-stage *Atlas* capable of putting a 5800-pound satellite in orbit to make television surveys of the moon, among other things. It is an essential preliminary for moon flight. Budget funding: $42.5 million.

Centaur—retarded. *Centaur* is similar but more powerful than *Vega*, designed to put 8000 pounds in orbit or to soft-land a 730-pound scientific load on the moon. Budget funding: $41 million.

Nova—eliminate or drastically reduce. *Nova* is the 1½-million-pound-thrust, single-chamber engine, producing in time a 6 million-pound-thrust cluster necessary to carry manned expeditions to the moon. Budget funding: $30.2 million.

Rover—reduce. *Rover* is the nuclear rocket for space travel.

Mercury—probably slowdown. *Mercury* is the manned satellite project.

Tracking and data acquisition networks—delayed. As necessary to space probes as precinct support to a Congressman.

New personnel—reduced by 15%. People are skills and training and competence. Without them no project can be accomplished.

What is likely to happen in the Senate or in Senate and House compromise?

The $22,725,000 lost on the points of order technicality will probably be restored. But the $45.5 million cut by the House Appropriations Committee will probably be lost entirely or at best partially restored. And, in the words of one high NASA official, the loss of even $20 million would affect the projects listed above.

The NASA budget request seems to us more than ordinarily reasonable. Some $100 million of it goes to support NASA research centers. Less than $375 million is new money for the space field. Compare this to a $40-plus *billion* defense budget in these days of a cold war where Russia uses her space exploits as an instrument of power politics; when she has convinced much of world opinion that success—or failure—in the space field is a measure of a nation's scientific progress.

At the risk of stepping on Pentagon toes, we would say—and earnestly—that the value of the United States of placing a man in space first, or of making a landing on the moon first—that either of these things is of more value to this nation in the cold war than a squadron of intercontinental missiles —which costs just about $100 million.

We believe that Administrator Glennan and his associates at NASA are doing a good and conscientious job. They don't pretend to have a magic formula for space exploration. If someone has such a formula they would like to see it.

Furthermore, we believe the NASA budget is honestly and tightly prepared. If for no other reason —and there are other reasons—the budget is too small to be otherwise.

AIR FREIGHT EXCLUSIVE

Radar keeps deliveries on time—another United Air Lines "extra" at no extra cost

United, as the only coast-to-coast airline with all-fleet radar, can promise you unmatched delivery performance and a smoother ride for fragile shipments. Whether your shipment goes by DC-6A Cargoliner or one of the 900-plus daily passenger flights, on-time schedule dependability is improved by radar, a feature customers appreciate.

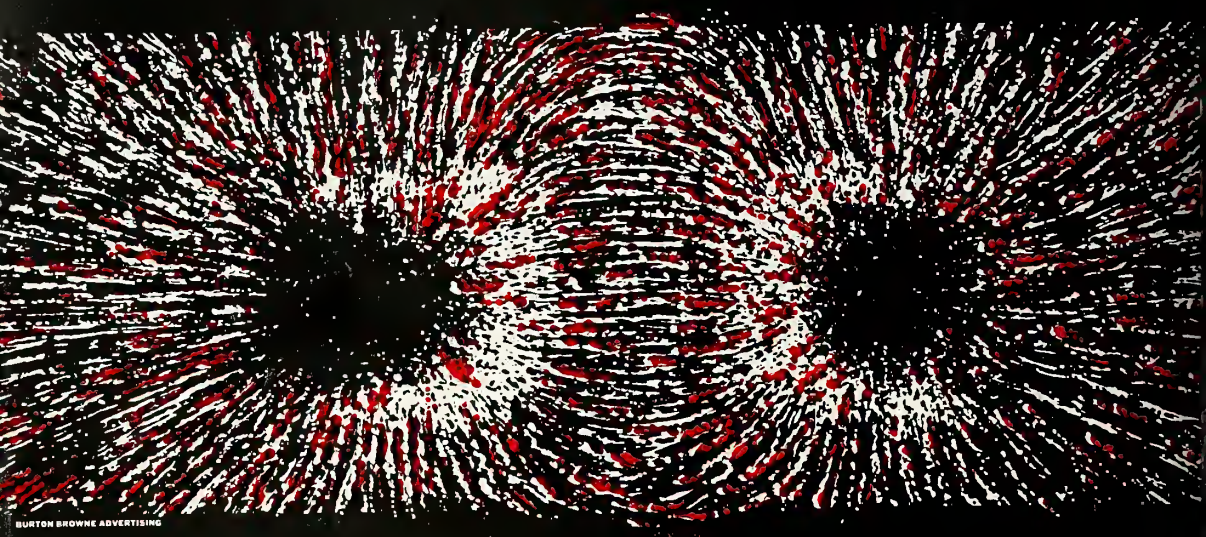
AND MORE "EXTRAS"

Reserved Air Freight guarantees you space aboard any United flight on as little as three hours' notice.

Personalized service—a follow-through feature, monitors your shipment from origin to destination.

Door-to-Door service—a convenient United feature for minimum handling, maximum speed.

Centralized cargo control insures that there'll be space on the flight you want when you want it.



FREE BOOKLET

Tells how United Air Lines saves shippers money, provides better service. How about you? Just write to Cargo Sales Division, United Air Lines, 36 So. Wabash Avenue, Chicago 3, Illinois.

YOU PAY NO MORE FOR EXTRA CARE WHEN YOU SHIP UNITED AIR LINES

FARADAY the FIELD and FREQUENCY RESONANCE

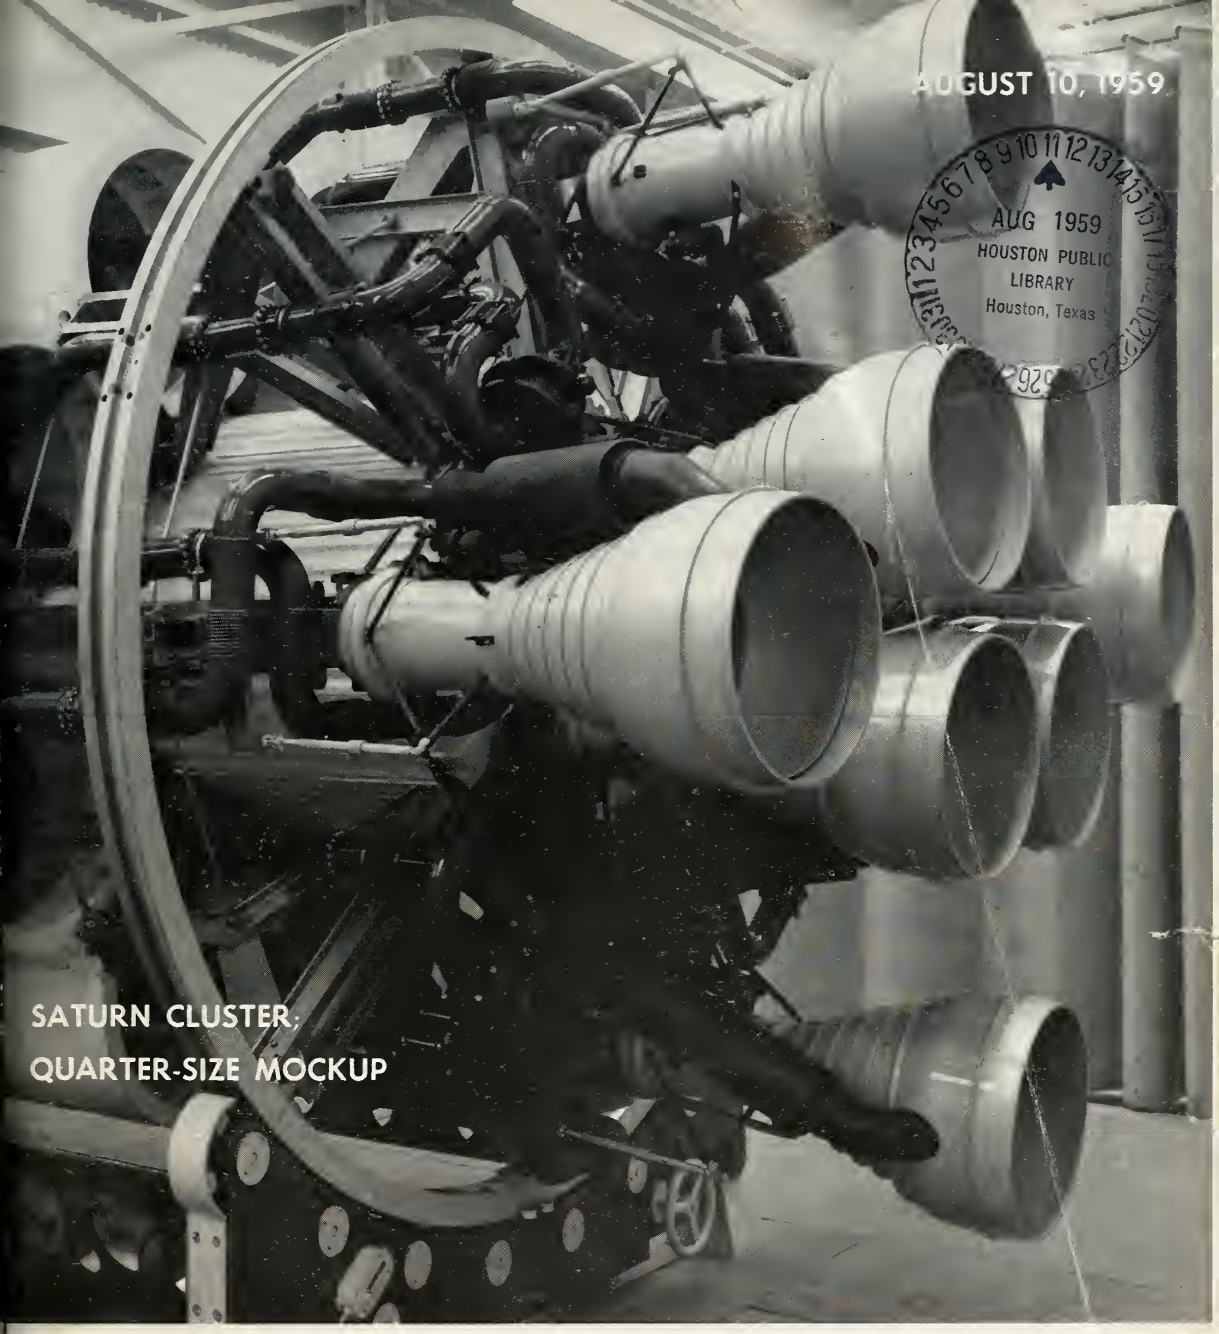
BURTON BROWNE ADVERTISING

Creative Imagination took Michael Faraday from the experimental discovery of the induction of electricity to the theory of "the field"—foundation of all the new physics including relativity.

Creative imagination at National Co. has taken the known unvarying resonance of the Cesium atom and translated it into a frequency producing instrument with a stability of frequency of 1 part in 10^{11}—this is man's most accurate measurement of time.

The applications and adaptations are many-fold and still largely unexplored.

National Co. is a community of minds and talents that enjoys the challenge and the prestige of success in such advanced fields as multipath transmission, noise reduction, correlation techniques for signal processing, Tropospheric scatter systems, Ionospheric scatter systems, molecular beam techniques, long range microwave transmission, and missile check-out equipment using microwave and digital techniques.



National Co. has grown with the Tradition of New England electronics. Your needs and problems receive exceptional attention at National Co. because, here, *creativity is required, recognized and rewarded.*

UNDER-SEAS WARFARE (USW) . . 24

AN AMERICAN AVIATION PUBLICATION

3 generations of airborne digital computers (but we can't show you their configurations)

In the photo above, the three ARMA computers have been intentionally deleted. But the cut-outs accurately represent the relative size of the three generations of ARMA airborne digital computers.

The larger size has been *in production* since 1957. The middle-sized one (a quarter the size of today's) will be in production in 1960. And the micro-miniaturized version in the engineer's hand will be operational in 1962—only .3 cubic feet in volume.

A production line unit of ARMA's curren model has operated in excess of 4000 hour without a component replacement. And th 1960 and 1962 versions will have reliabilit factors at least equal to this.

With this program of miniaturization ARMA has made the digital computer truly airborne. ARMA . . . Garden City, Nev York. A division of American Bosch Arma Corporation.

THE S. S. White Industrial Airbrasive® Unit

Not that we advise doing this to your fine crystal glassware, but it seemed to us a dramatic way to show you the versatility and the cool, shockless cutting and frosting action of our Industrial Airbrasive Unit.

Cuts as fine as .008" or large frosted areas are equally easy to make with this amazing industrial tool. A gas-propelled stream of abrasive particles quickly slices or abrades, as needed, almost any hard, brittle material, such as fragile crystals, glass, oxides, metal, minerals, ceramics.

Applications range from printed circuits, wire-stripping potentiometer coils, and cleaning off oxides... to shaping or drilling germanium. Every day new uses for the Airbrasive Unit are being discovered.

Send us your most difficult samples and we will test them for you.

SEND FOR BULLETIN 5705A . . . Complete information.

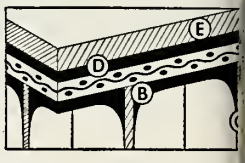
Materials Memo

3M reports on SNAP III . . . heat reflective tape . . . adhesive welding



Many of the 27,000 different products manufactured by Minnesota Mining and Manufacturing—the 3M Company—have proved valuable in missile manufacturing and space research. Here is information on newer products . . . and up-to-date ideas and applications for some established products:

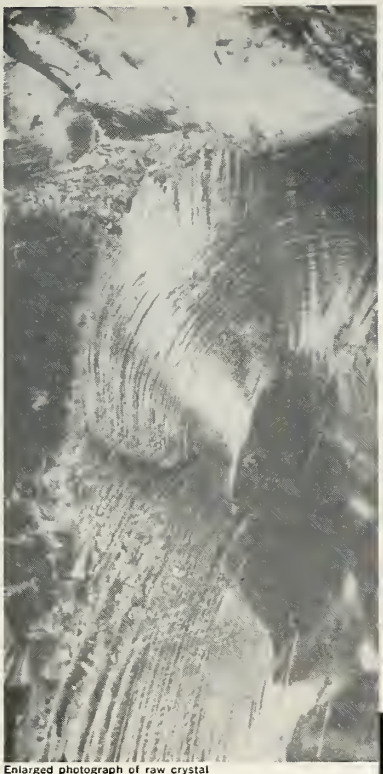
■ **SEEBECK & PELTIER, 1959:** Over 100 years ago, in 1829, the German physicist, Thomas Seebeck, discovered that heat applied to one junction of two dissimilar metals in a circuit would produce an electrical potential. The reverse of Seebeck's effect was discovered in 1834 by Jean Peltier when he found that a current passed through the junction of two dissimilar conductors caused heat to be absorbed or given off. Because of the poor conversion efficiencies of available materials, applications of these principles have, until recently, been limited to temperature measurements. But about 10 years ago, a major breakthrough led to the development of new and more efficient conductor materials. Now the Seebeck Effect is headline news: The 1959 development of the first working thermoelectric generator, SNAP III, designed and built by 3M for the Martin Company and the AEC. This unit directly converts heat of radioactive material into electrical energy. Depending on the isotopes used, a 5-lb. generator could provide 5 watts of electricity for one to many years. For comparison, 1,500 lbs. of batteries would be needed to supply 5 watts for one year. Peltier's principle, on the other hand, has led to development of a new 3M Heat Pump. Because of the wide-spread interest in these materials, we now offer a test kit that will let you experiment with heat pumps yourself. Kit contains an assembled Model E-8 heat pump; four extra "P" type elements; four extra "N" type elements; complete instructions—is available for $75. Send your purchase order to Electrical Products Division, 207-1, Dept. 1442, 3M Co., 900 Bush Ave., St. Paul 6, Minn.

■ **HOT TEMPERED TAPE:** One of the latest of the more than 370 pressure-sensitive "SCOTCH" Brand Tapes has unusually good heat-reflective properties. No. Y-9014 can protect plumbing and other hardware from high intensity radiant heat; protect thermally sensitive materials from 5000° F. radiation for short periods. Basic construction is glass cloth laminated to highly-reflective aluminum foil, with a specially compounded pressure-sensitive silicone adhesive. It stands up well under continuous duty at 500°. (Under development: Tape that will withstand 800-850° F.!) You can find this tape liberally applied in engine compartments of some of our big-birds. And wouldn't it be useful in and around high-temp air-breathing jet airplane engines? For complete information on this, or any of the other "SCOTCH" Brand Tapes, call yo 3M Industrial Tape salesman, or write: Missile Indust Liaison at the address below.

■ **SPACE AGE ADHESIVES:** The last 10 years ha seen adhesive technology move a long way from anim glue and gooey surgical tapes. Today adhesives are i creasingly regarded for structural joining. As example Today most helicopter blades are fabricated with structur adhesives. Intricate castings are now being made in sever simple parts which are then bonded together to form t whole. Advanced aircraft and Missiles are built with a hesive bonded honeycombs. And 3M research has led t way in these new advances in adhesive technology. Yo 3M AC&S salesman will be glad to give you the comple story. "AC&S", incidentally, means "Adhesives, Coatin and Sealers." There's more to the operation than just sticking things together!

GREATER BOND AREA: One side of "3M" Composite Adhesive Film (a) is coated with dry filleting epoxy (b). Under heat, this epoxy turns liquid, wets deep into t honeycomb (c), then cures chemically to a high-streng solid fillet. Elastomeric adhesive (d) on the opposite si of film, bonds firmly to skin material (e). Sandwich bo has controlled thickness; is tougher and far less mes than previous sandwich construction adhesives.

■ **ABOUT "MIL":** 3M's Missile Industry Liaison is service staffed by technical personnel experienced in rocl propulsion and other phases of space technology. Th job is to translate problems of the aerospace industry those 3M specialists best qualified to solve them. If y have questions on any of the items mentioned here, would like to know what else 3M makes—or **could** ma —for your needs, write: 3M Company, Missile Indus Liaison, St. Paul 6, Minn., Dept. VAA-89.



DESCRIPTIVE BROCHURE shows cro sample of 3M Products for missile a space uses. For free copy, write: 3M C Missile Industry Liaison, St. Paul 6, Min Dept. VAB-89.

"SCOTCH", AND "3M" ARE REGISTERED TRADEMARKS OF 3M CO., ST. PAUL 6, MINN.—EXPORT: 99 PARK AVE., NEW YORK 16. CANADA: LONDON, ONTARIO.

BULOVA CRYSTAL CONTROLLED ULTRA-STABLE SHIFT OSCILLATORS

Bulova shift oscillators are all that any electronics engineer could ask for in miniature crystal controlled packages!

Consider this new Bulova custom designed 18.5mc shift oscillator. Here's an assembly of two oscillators operating at 18.5mc. One is fixed, with a 1 pp 10^7 stability. The other is a variable with equal stability, 1 pp 10^7. The shift is accomplished by means of a variable air capacitor. However, the same shift, at the same frequency, can be affected with a varicap.

This new ultra-stable shift oscillator is only one of many recent advances made by Bulova Electronics. For information on these specific units, or on how Bulova experience, in mastering component and system reliability, can help your program, write—

Department A-1361, Electronics Division, Bulova, 40-06 62nd Street, Woodside 77, New York

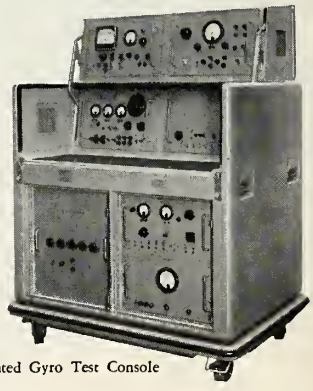
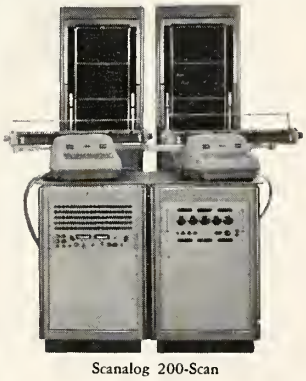
GROUND SUPPORT EQUIPMENT

A Proven Kearfott Capability – Kearfott's prominence in the design and production of ground support equipment is a result of 15 years' experience in producing precision servo systems, computers, gyro reference systems and inertial guidance equipment. Kearfott test equipment is designed on modular principles which increase flexibility and economy and eliminate the obsolescence factor since modules can be readily modified or replaced. Modules are designed to be compatible with one another, thus providing test capabilities for a wide variety of applications.



Inertial Guidance System Test Console

IN-PLANT TEST EQUIPMENT: Rack-mounted modules comprise the necessary metering circuits, signal generators and power supplies, switching circuits and junction boxes to perform the following tests on inertial reference systems:



Voltage and phase • Current • Heating cycle checks • Verticality of platform in ground erection mode • First order erection time in ground erection mode • Measurements of platform roll and pitch output angles in ground erection mode • Measurements of free drift of platform in azimuth in ground erection mode • Measurement of azimuth gyro torquer scale factor in ground erection mode

FIELD-TYPE TEST EQUIPMENT: Modularized, self-contained unit that provides all power and signal voltages to operate, test or trouble-shoot a gyro. All inputs to and outputs from the gyro are accessible at convenient jacks where connections to measuring equipment can be made, thereby enabling operator to evaluate gyro performance completely. Modules are slide-mounted for ready access if repair, modification or product improvement replacement are required. This portable equipment performs these basic tests:

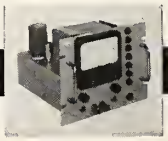
Insulation resistance • Warm-up time • Torquer scale factor measurement Gyro transfer function • Free drift • Gimbal offset drift • Continuity Signal Generator Null • Phasing • Gyro drift • Fixed torque restraint

Floated Gyro Test Console

Scanalog 200-Scan
Alarm Logging System

GENERAL PURPOSE DATA PROCESSING: This data handling system provides a reliable, precise means of monitoring, logging and performing an alarm function of up to 200 separate temperature, pressure, liquid level or flow transmitters. Manual controls are provided for scanning rates, automatic or manual logging, data input relating to operator, time, day, run number and type of run. 200 numbered lights, corresponding to specific points being maintained, provide a visual "off normal" display for operator's warning. This system has growth built in and can be expanded in capacity to 1024 points and in scanning rate to 2000 points per second.

Write for complete information on Kearfott's ground support equipment.



Engineers: Kearfott offers challenging opportunities in advanced component and system development.

Washington Countdown

IN THE PENTAGON

Put *Polaris* in cruisers . . .

This is a Navy battlecry that you can expect to hear increasingly in the months ahead. The Navy believes firing the **Lockheed** missiles from cruisers would be easier to do than firing them from submarines. And it feels that *Polaris*-packing cruisers would be a natural strategic partner to the underwater fleet of *Polaris* subs.

• • •

Two types of rocket belt . . .

may be adopted by the Army. One—a light model that can be strapped around the waist—would be used for short jumps over obstacles. The other—a more elaborate harness with bigger rockets—would be used for longer one-man hops.

• • •

An anti-submarine satellite . . .

is under study by the Navy. Details of the project are highly classified. However, the satellite undoubtedly is being looked at as a means to solve the tough detection problem. (See page 24)

• • •

Number of *Lacrosse* battalions . . .

in FY '61 is very iffy with numbers being tossed all over the park. It's definitely decided, however, to equip eight battalions this year. Two more are to be activated before December and one battalion in March, April, May and June.

• • •

Navy also requires *Mauler* . . .

and, sources say, wants to put funds into its R&D. (See p. 13)

• • •

Army's new "vest pocket" system . . .

for tactical air defense probably will soon go to NATO forces as well as U.S. units in Europe. The Army can be expected to seek at least another 30 of the mobile **Hughes** units in the not too distant future to go with missile batteries already in the field. (See page 45)

ON CAPITOL HILL

American missile shipments . . .

to NATO forces will not necessarily be cut during the next year because of congressional multi-million dollar slashes in the foreign aid program. The Administration can probably find elsewhere in the big program the $302 million it planned to spend on missiles for NATO in FY '60.

• • •

Congressmen remain pessimistic . . .

about the chances of the Administration taking up Congress' desire for ordering eight more squadrons of **Convair** *Atlases* this year. The House and Senate have made an $85 million down payment on the extra squadrons available. But the Administration has made clear that it has no intention of making the $800 million commitment for the squadrons unless the international situation should change for the worse.

AT NASA

With one *Vanguard* . . .

attempt yet to go, fairly complete figures indicate that the "work good when it works" bird costs $3 million per shot.

AROUND TOWN

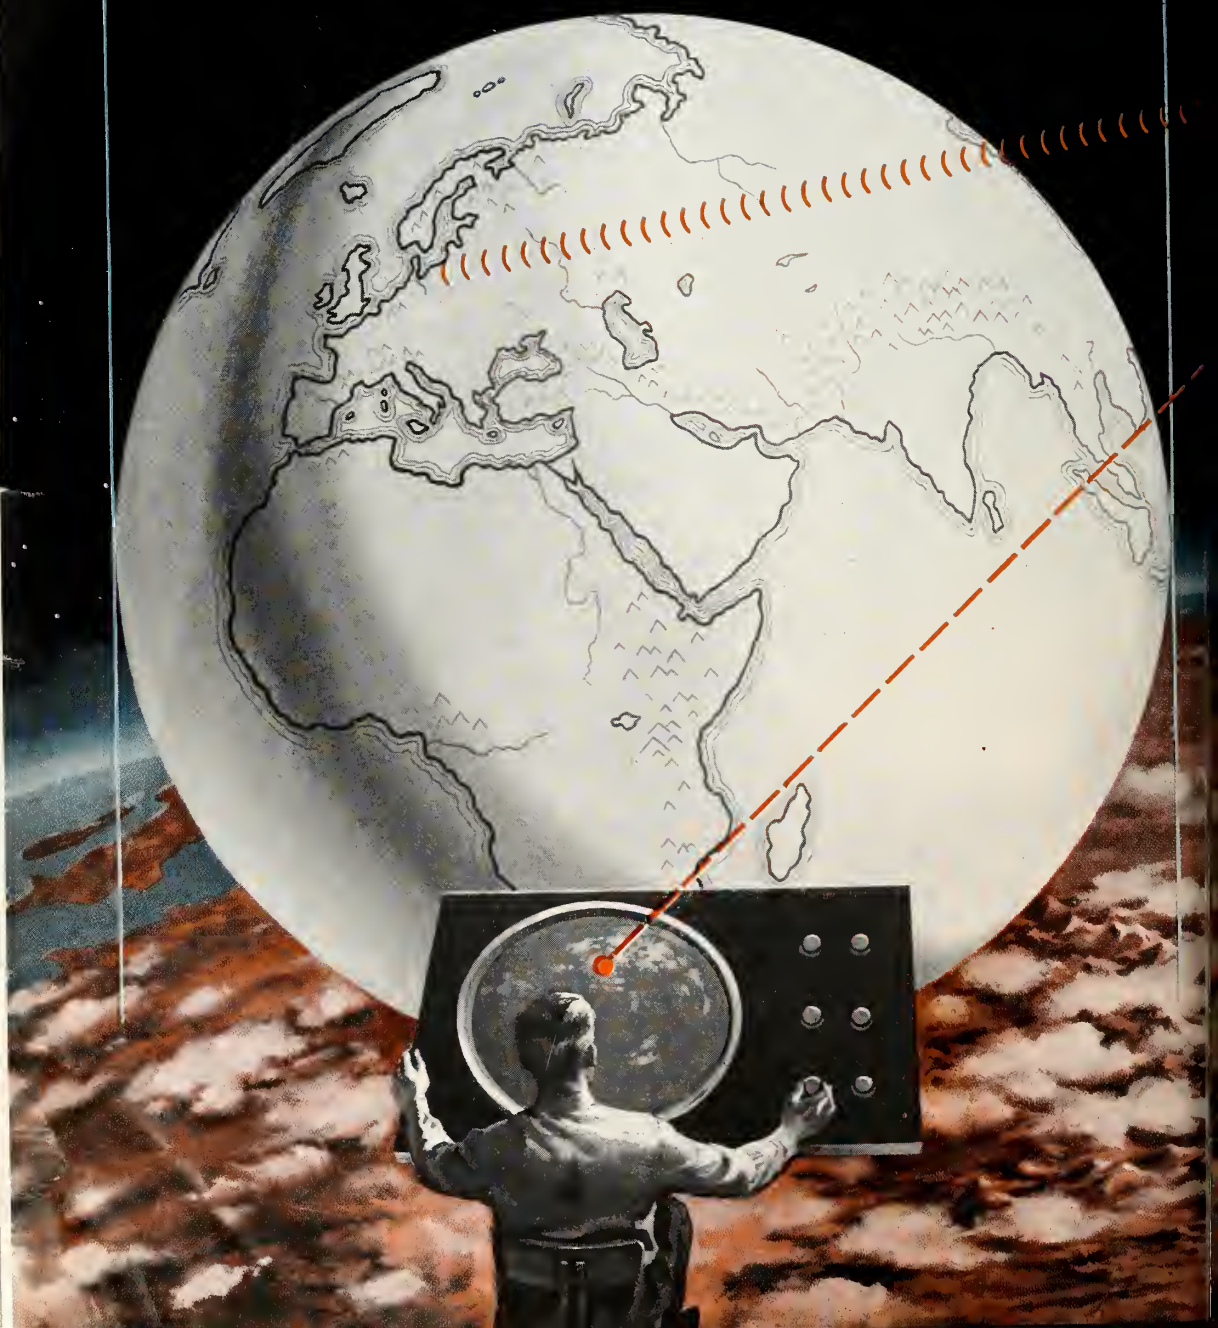
Watch for Japanese . . .

to make an official protest to the Soviet Union about Red missile firings passing over Japanese territory. The Japanese are already irritated about the Russian action several years ago banning their fishing ships from the Sea of Okhotsk and parts of the Bering Sea, claiming them to be contiguous to Russian territory. Japanese sources say that Russian missiles are landing in these waters, and that longer range missiles are passing over Japan itself.

Other reports . . .

. . . Some military and space planners are worried that Soviet Premier Khrushchev's forthcoming U.S. visit may take a lot of the starch out of U.S. missile-space efforts . . . On the other hand, Russia could decide that now's the time to announce another spectacular Soviet space achievement.

. . . The Air Force is considering establishment of a Ground Electronics Systems Center to control development of electronics systems in all AF weapons. This would split the weapon system concept.



. . . Vice President Nixon will work behind the scenes for more money for the U.S. space program in the '61 budget.

Marquardt

ADVANCED SIMULATOR-TRAINING SYSTEMS

FOR AIR AND SPACE

UNIQUE MARQUARDT CONCEPT SHRINKS EARTH TO 14-FEET

Advanced land mass simulation concept demonstrates Pomona Division capability in realistic simulators for lower-cost training of America's air and spacemen.

IN DEVELOPMENT:

A Marquardt-conceived land mass simulation system that shrinks the map scale factor to 1:3,000,000, while enabling the operator to distinguish landmarks smaller than a football field from any altitude! Application today: ground-training airmen for intercontinental missions at great savings in cost — using a single 8-foot map to realistically simulate the radar reflectivity and shadow effects of a 4,000-mile mission. Application tomorrow: training the free world's first space explorer for his safe return to earth.

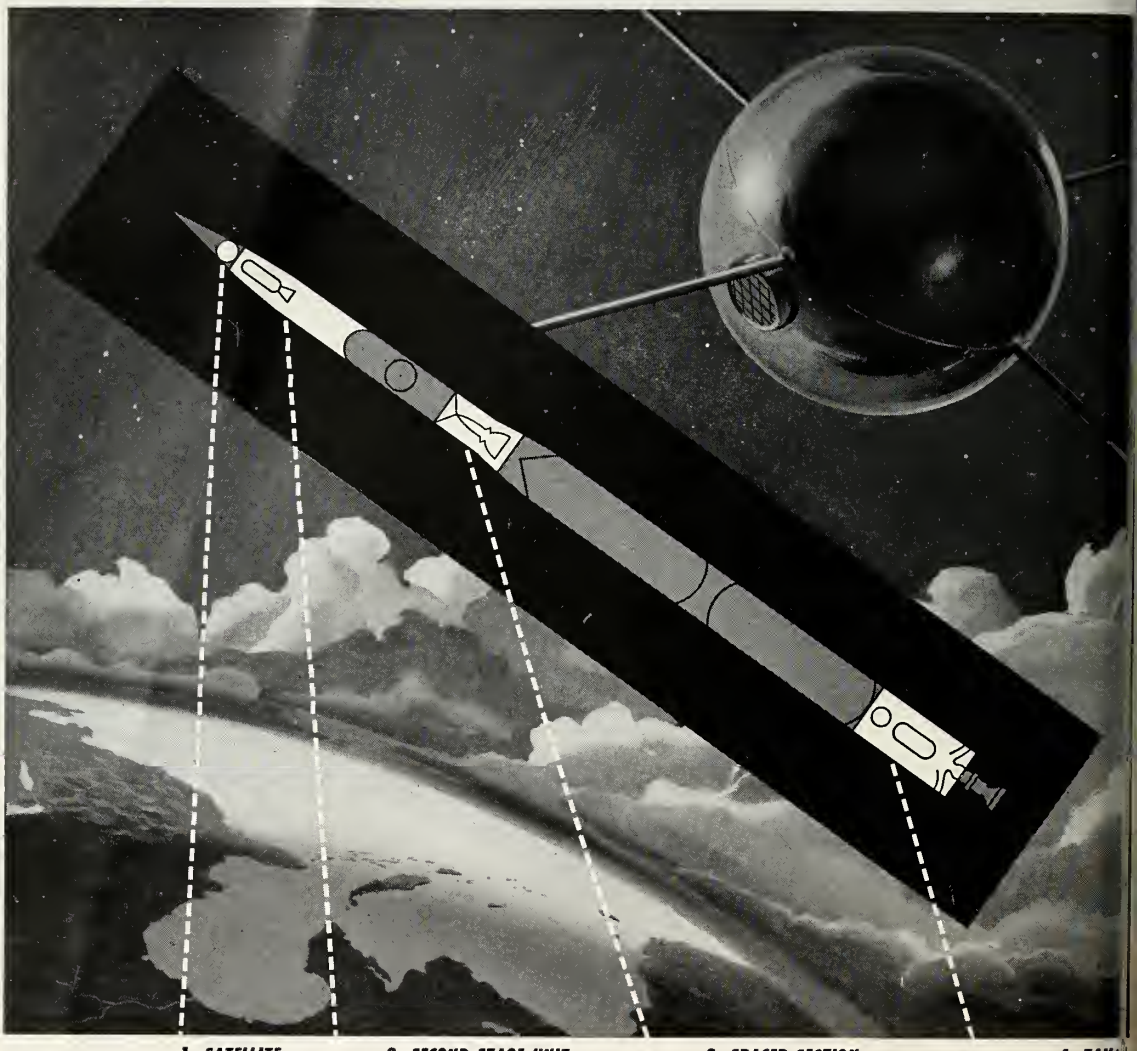
IN PRODUCTION TODAY:

Pomona Division's AN/GPS-T4 Radar Signal Simulator, a relatively low-cost training system that is simple, compact, flexible and realistic; producing synthetic target and IFF video information for radar display. Current mission: training USAF aircraft controllers to direct interceptor missions. Ready adaptability will permit the T4 to simulate missiles, radar surface targets and sonar targets.

IN THE U.S. DEFENSE INVENTORY:

The USAF's AN/APQ-T1, AN/APG-T1A, AN/APQ-T2 and T2A, and AN/APQ-T3 simulator-training systems, plus the USN's 15WV-2 AEW/CIC trainer system — all developed and manufactured by the Pomona Division and its predecessor companies. Numerous sub-systems, up-dating modification kits, adapters, spares, and a worldwide field service section add to the organization's total experience.

POMONA DIVISION of The Marquardt Corporation is an able and experienced organization with demonstrated capability in advanced research, design, development and production. The result is reliable hardware which provides solutions to the problems of training military operational personnel.



Drawing on the Corporation's overall management-engineering skills, additional facilities and financial support, Pomona Division now offers industry and the Armed Forces a unique and proven ability to get the job done—delivering vital simulator-training system both on-time and at minimum cost.

DOW | MAGNESIUM PRODUCTS

1. SATELLITE
The rigid external skin of the weather satellite is made of magnesium alloy, AZ31B. It is plated with gold and other materials to reflect heat.

2. SECOND-STAGE UNIT
The skin is made of HK31A, magnesium-thorium alloy sheet. This elevated temperature alloy must withstand temperatures of 700° F. and above.

3. SPACER SECTION
The skin is formed of AZ31B magnesium alloy sheet. Magnesium was selected for its light weight and high strength-to-weight ratio.

4. TAIL
Again AZ31B magnesium alloy chasen because it is the world's ligh structural metal.

LIGHTWEIGHT MAGNESIUM SPEEDS WEATHER ROCKET FOUR WAYS

The shell of the satellite and several parts of the Vanguard Rocket are made of standard magnesium-aluminum-zinc and magnesium-thorium alloys. Why was magnesium chosen for this project? Because it is the lightest commercially available metal that could be easily fabricated—one with a high strength-to-weight ratio and able to withstand elevated temperatures encountered during flight. Magnesium alloys met these demanding requirements, as pro by tests conducted by the Naval Research Laboratory Washington, D. C.

Industry Countdown

MANUFACTURING

***Missile A* competition . . .**
winner announcement is to be announced momentarily. Prime contract will go to **GE's Missiles and Space Systems Division.** Funding decision confirms M/R story (March 30, p. 13). While no official announcement has been made, sources inform M/R that **Convair** has go-ahead on the *Mauler* competition, an infrared homing missile for use against low-flying aircraft. *Missile A* is 65-70 mile range solid propelled successor to the *John* family.

Labor demands for coming year . . .
will include: equal pay for equal work; severance pay; per diem and expenses when relocating to another plant (now included in a **Lockheed** contract) and 15 cents more an hour.

• • •

Look for new IAM-UAW coalition . . .
to campaign for some kind of contract protection against surprise cancellations of missile/aircraft work. In forthcoming negotiations union bargainers may ask for job security provisions against sudden layoffs.

• • •

Single collective bargaining . . .
pact worked out last week by IAM-UAW will be tried out first in negotiations with **United Aircraft's Pratt & Whitney Division.** Contract expires in December; most other major contracts are up for renewal in the first half of 1960.

• • •

Keep an eye on $100 million . . .
oceanographic research program recommended by National Academy of Sciences National Research Council. It could be another good market for missile, rocket and spaceflight knowhow. Ten-year project would entail direct procurement of deep (18,000 feet) and mid-depth submarines, 36,000-foot bathyscopes and a great variety of other instrumentation akin to missile/space requirements.

PROPULSION

Best analysis . . .
of **Phillips Petroleum** withdrawal from its **Astrodyne** partnership with **Rocketdyne** is that Phillips decided small government contract profit didn't offer as good a percentage return on investment that could be obtained in normal commercial operations.

• • •

Latest model Rocketdyne X-1 . . .
from which company has developed all its liquid rocket engines now has only two basic components—turbopump and combustion chamber. A couple of years back there were 10 times that number of components.

• • •

Navy will use $3.5 million . . .
order of **Thiokol** Guardian II rocket motors for off-the-shelf stock as well as propulsion system for supersonic target drone being developed by **Temco.**

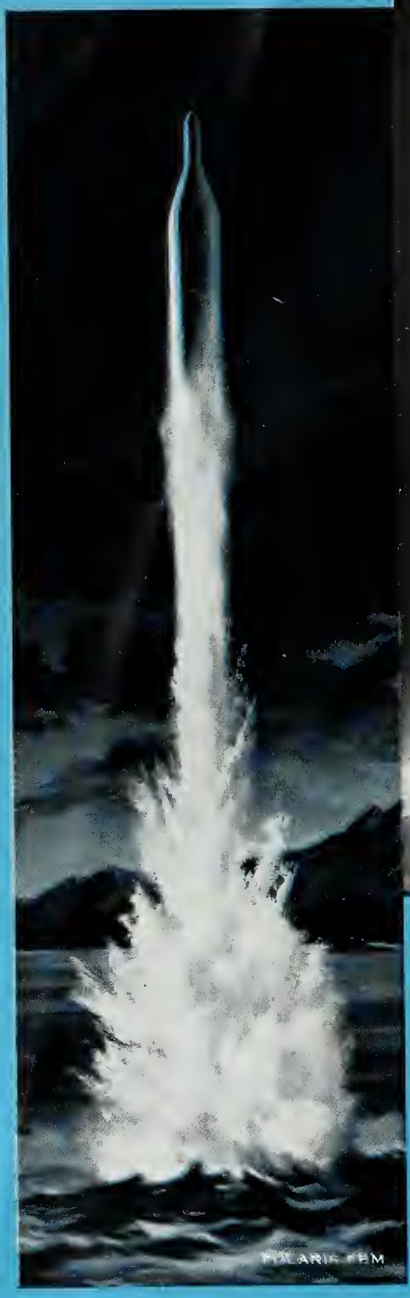
• • •

First silo shot . . .
of **Boeing** *Minuteman* with first stage solid-fueled **Thiokol** engine is due shortly at Edwards AFB. Engine will be scaled-down prototype with very limited thrust. Shot primarily will be test of configuration of the 100-foot silo.

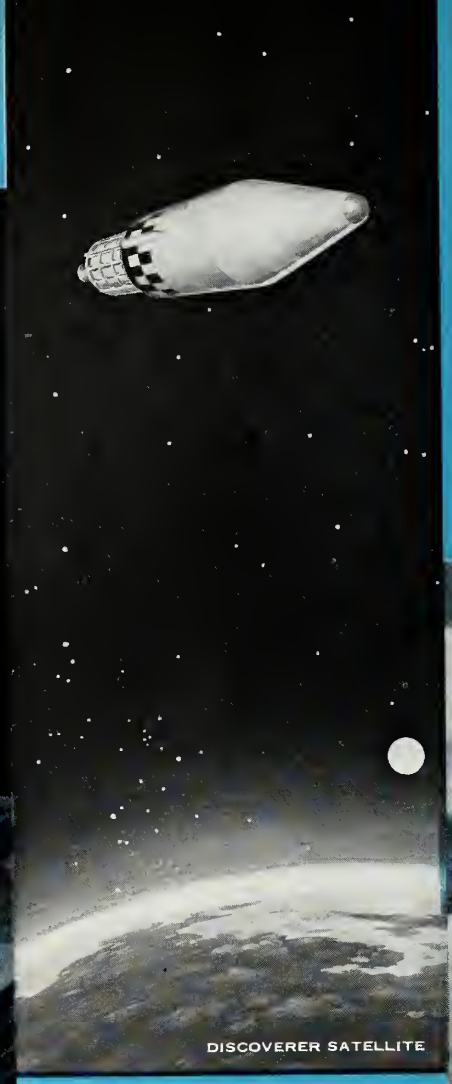
ELECTRONICS

Uninterrupted telemetry . . .
transmission during atmospheric re-entry reportedly has been developed by **Avco** scientists. Hush-hush method penetrates ionized layer which builds up around re-entry vehicle and heretofore has blacked out radio signals.

• • •

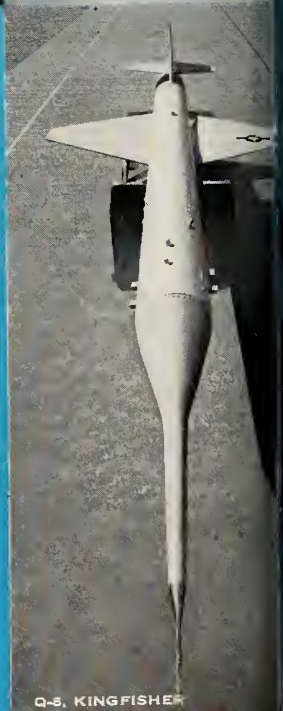


Big problem in engineering . . .
Mercury "satellite clock" programmer is gravity. **Waltham Precision Instrument Co.** must design it to operate in space where there is no gravity, and this means developing entirely new means to achieve zero gravity conditions on earth to test the device before it is sent aloft.

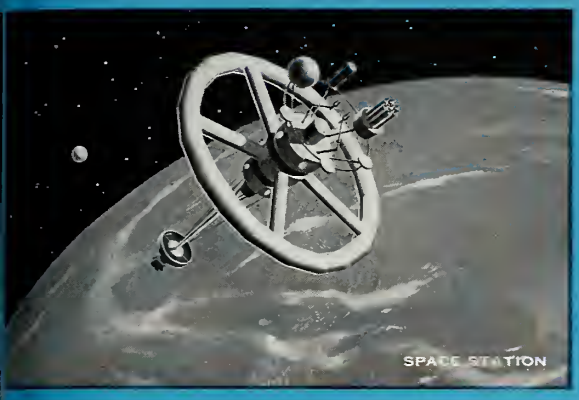


WE HEAR THAT—

Underground missile sites . . .
are being sought by British Air Ministry geologists for *Bluestreak* IRBM squadron—and perhaps for *Titan.* Trouble to date has been in finding militarily suitable locations which have proper subsoils . . .



Richard Boutelle, former president of **Fairchild Engine & Airplane Corp.,** now is reported to be a consultant to **AC Sparkplug Division** of **General Motors** . . . Merger of **Victoreen Instrument and Tenney Engineering** will produce one company with combined annual sales of $15 million . . .



Restraint reel and harness systems for *Mercury* astronauts are under development by **Hardman Tool & Engineering Co.,** Los Angeles . . . Hardware for Naval Research Laboratory sun flare investigation consists of 12 **Cooper Development** *Aspan* rockets which weigh 1760 pounds apiece and can boost a 50-pound payload to 150 miles. They require only a 60-second countdown . . .

DISCOVERER SATELLITE

Q-5, KINGFISHER

EXPANDING THE FRONTIERS OF SPACE TECHNOLOGY

■

ADVANCED PROJECTS AT LOCKHEED

POLARIS FBM—Lockheed is missile systems manager for the Navy POLARIS Fleet Ballistic Missile, under the cognizance of the Special Projects Office of the Bureau of Ordnance. Submarine-launched, the POLARIS will travel through three mediums in a single flight: water, air and outer space. With three-quarters of the earth's surface being water, practically no target in the world is outside its range. The solid-propellant POLARIS was *designed with the future in mind*—an approach that the Navy states has cut nearly two years from the original timetable.

DISCOVERER SATELLITE; MIDAS; SENTRY Designed and built by Lockheed Missiles and Space Division, the first of a series of DISCOVERER satellites was successfully placed in orbit in February. The Division has also been assigned the responsibility of systems manager for PROJECT MIDAS – an early warning system against ballistic missile attacks. The project will investigate the use of infrared sensors for detecting aggressor missiles at the moment of launch; and PROJECT SENTRY—an advanced satellite reconnaissance system. DISCOVERER, MIDAS and SENTRY are programs of the Advanced Research Projects Agency under the direction of the Air Force Ballistic Missile Division.

X-17—The nation's first successful reentry tests were conducted by the Air Force with the three-stage, Lockheed X-17 solid-propellant ballistic missile. The X-17 has pioneered many new techniques and the valuable experience gained from this program has facilitated development of other, inter-service projects, including the Navy POLARIS FBM. The Navy's history-making, 300-mile-high, Project Argus radiation explosions featured the X-17 as the vehicle.

Q-5, KINGFISHER—Developed for the Air Force, and currently being manufactured for the Army, the Kingfisher is designed to simulate enemy attacks to test the efficiency of our various defensive weapon systems. It is equipped with extensive instrumentation to register "kills" without itself being destroyed and can be recovered by parachute and landing spike to be used again, with marked savings in cost.

X-7—Lockheed's X-7 recoverable ramjet-engine test vehicle, developed for the Air Force, has established speed and altitude records for air-breathing vehicles and is also recoverable for re-use following flight.

SPACE STATION—An orbiting research facility, to serve as an advance base for space exploration, has been proposed in practical detail by Lockheed's research and development staff. The station would carry a 10-man crew. Prefabricated compartments for the rim of the wheel, the spokes, and the three hubs would be launched separately by means of ballistic missiles and guided into a cluster on the same orbit.

The successful completion of projects such as these requires a bold and imaginative approach to entirely new environments. Lockheed's programs reach far into the future. It is a rewarding future which scientists and engineers of outstanding talent and inquiring mind are invited to share. Write: Research and Development Staff, Dept. H4-29, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship required.

Pick Your War – Then Plan for It

Pentagon's new instruction on industrial readiness planning leaves it up to individual services to choose type of war and make industry gear to match decision

by James Baar

WASHINGTON—The Defense Department is dramatically demonstrating once again its inability to answer the multi-billion dollar mlitary question: What kind of war should the nation prepare for in the Missile Age?

The demonstration is made for all to see in the Defense Department's new Instruction on Industrial Readiness Planning—a detailed outline of how the three services should go about making industrial war mobilization plans.

The multi-billion dollar missile-space market is caught directly in the middle.

In brief, the Pentagon has three obvious choices on which to base war mobilization planning:

- Total all-out war. This would begin with a catastrophic exchange of nuclear weapons and could be expected to conclude shortly thereafter.
- Limited war. This would be another Korea-type war—a war fought for a relatively short period in a limited area for limited objectives.
- General war fought without the big warheads. This would be a long war involving only conventional and possibly small fractional-yield nuclear weapons.

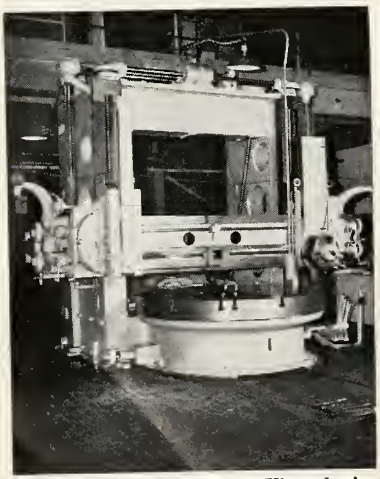
The United States could prepare to fight all three kinds of war. That is what Russia has done. Or, the United States could make a clear-cut decision on one or even two types.

But the Pentagon and the Administration have decided against taking either course at the present time. Instead, the Pentagon has clearly decided to let the decision continue to ride.

In effect, the new Defense Planning Instruction tells each of the three services to make industrial plans for whatever kind of war each believes would be the correct one to plan for under the present circumstances—budgetary and strategic.

As a result, the Air Force can be expected to proceed with its present policy of planning strictly for all-out nuclear war. This means little or no industrial war planning.

On the other hand, the Army and Navy can be expected to continue to proceed with their present policies of planning for limited and general wars fought without the big nuclear weapons. This involves millions each year.

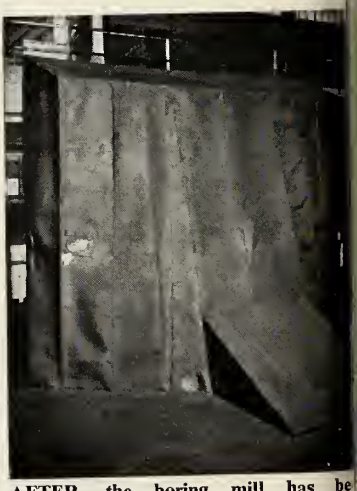


- **How it started**—Industrial war planning dates back to the early years after World War II. The governme decided that it would never again caught in the state of industrial unp paredness for war that it was in af Pearl Harbor.

Therefore, the government began vast program of stockpiling critical w materials. The services also put ir effect industrial preparedness and pla ning programs involving projects rar ing from drawing up paper mobili tion plans to mothballing factories.

The United States today has a st tegic material stockpile involving penditures and obligations totali nearly $6 billion. These include so 75 materials running from aluminu to manganese to zinc—not to for wattle and waterfoul feathers. All stored at some 216 depots and oth facilities throughout the nation.

Purchases of a number of items continuing. However, for most ite both basic and maximum objectiv have been achieved.



The Army has in reserve 73 plan for mobilization purposes—38 inacti and 35 active to varying degre Thirty-five are ammunition plan Twenty-six others for some type ordnance. Five of these are in the Arr missile program.

BEFORE mothballing, a King boring mill awaits joining machine tool reserve.

PART WAY, the boring mill is covered with protective paper and frame.

AFTER, the boring mill has be shrouded with heavy protective materi

The Army also is maintaining more han 169,000 items of war production quipment in storage. About 60% of hese items are part of plants in the rmy industrial reserve. Some are tored in big Atchison cave in Kansas.

The proposed Army budget for FY 50 provides $76 million for its in- ustrial mobilization program. But this s not a true picture of Army expendi- ures in this field. Many costs are scat- ered elsewhere.

The Navy is spending about $110 to 120 million a year on its mobilization rogram. However, the Navy is spend- ng only about $12 million on industrial obilization planning. The bulk of the oney goes for purchase of mobiliza- ion stocks and maintenance of the big othball fleet.

The mothball fleet today is made up f nearly 1400 ships of all types. These nclude 47 carriers, 15 battleships, 54 ruisers, 121 destroyers and 44 sub- arines.

The Air Force now is doing prac- ically no industrial mobilization plan- ing except for a number of very lim- ed programs. However, the new Air orce budget includes $40 million for ar readiness material. Most of this is or such rapidly consumed items as uxiliary fuel tanks for tactical jet ircraft.

• **Clarification overdue**—These learly divergent programs and the asic policies behind them has made it bvious for sometime in industry and ilitary circles that clarification of entagon policy on industrial war plan- ing was much overdue. Naturally, ny such clarification would also in- olve clarification of Pentagon policy n the far broader issue of limited vs. otal war.

But Pentagon officials faced great ifficulties in doing any such thing.

Money, of course, was and still is the main stumbling block. If there is enough cash, you can plan for all kinds of wars. But, when you have to operate under a $40 billion annual ceiling, you have to make some tough decisions.

The Air Force theory has been that the most likely war would be a total war no matter how it started. Therefore, it has argued that its limited funds should be spent on building and maintaining the most powerful force-in-being possible.

This policy is based on the conclusion that in any total war only the forces that the United States can bring into action at the beginning would have any meaning.

There would be no time to take plants, machine tools and ships out of mothballs. There would be no time to begin producing thousands of new missiles. There would be no time to order the manufacture of 50,000 planes.

Moreover, an all-out nuclear attack would make rubbish out of most advance planning along with much of the nation's industry and huge strategic stockpiles.

The Army and Navy have countered that limited wars similar to the Korean War and smaller are far more likely than total war. Therefore, industrial mobilization planning, stockpiling and mothballing of equipment are vital.

The Air Force reply is that it is not opposed to planning for such wars. But it argues that first the Defense Department should come up with an overall plan of what kind of limited war to plan for and someone should provide the money.

In any assessment of all of these arguments, it must be remembered that the Administration policy continues to be preparation for total war.

The Army's high-readiness reserve factories can be operating within three to four months. But the Army itself is not designed to meet the vast armies of Communism in any sizeable land war fought with conventional weapons.

After extensive review of all this, the Defense Department came up with its new War Planning Instruction—a broad compromise.

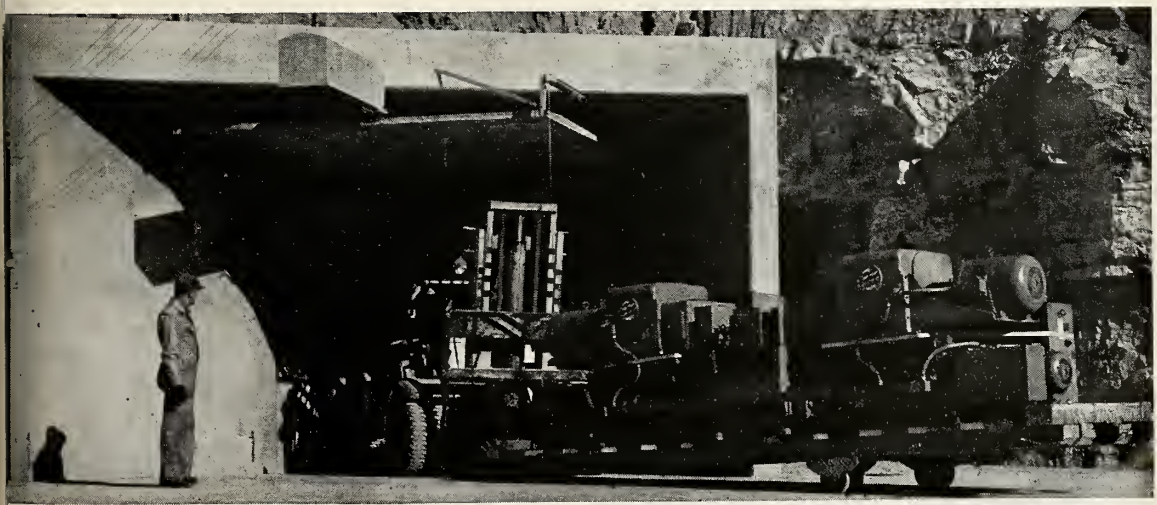
• **Possibilities**—The new instruction offers seven broad possibilities:

• Acceleration Planning. This is aimed at having current producers increase their rate of output in conflicts short of general war.

• Conversion Planning. This involves arrangements under which a manufacturer plans to produce in an emergency products that he does not normally produce.

• Compression Planning. This involves increasing a current contractor's normal production inventory so that in a national emergency he can complete a maximum number of finished products on a crash basis. The assumption in such planning is that all sources of supply have been destroyed.

• Subcontract Planning. This involves elimination of delays in an emergency.



• Supplier Planning. This is aimed at production of normally commercial items that have a military application.

• Industry Preparedness Measures. This ranges from surveys of possible production problems to operation of pilot assembly lines.

• Special Studies. These are such things as broad surveys that might be needed from time to time.

Finally, the Defense Department left open the possibility of approving any other type of planning that any of the services might believe desirable.

In other words, pick your war and plan for it.

UNDERGROUND in huge Atchison Cave near Atchison, Kansas, the Army stores part of its big mobilization stockpile.

Antennas: There's a Limit in Size

What's needed is the ability to manufacture dishes and maintain them in an exposed environment to the close tolerances required

by Hal Gettings

WASHINGTON—What's needed in antenna design and fabrication to meet the extreme range requirements of missiles and space vehicles?

For example purposes, let's cite a 600-foot monster antenna now being constructed near Sugar Grove, W.Va. Costing $60 million and scheduled for completion in 1962, the Naval Research Laboratory facility will be able to look 38 billion light-years into space.

But the design of this unit merely serves to point up the emphasis being given to the extreme range requirements necessary for tracking. Boiled down, it means antennas must become bigger—because gains require larger apertures. And they must be better—because there appears to be a limit to bigness and advancement must also come in other areas.

Long-range communications can be improved by increases in three areas, under the present state-of-the-art: transmitter power, receiver sensitivity, and antenna gain.

Higher transmitter power is being obtained with new tubes and techniques. Receiver sensitivity is being increased with MASERS and parametric amplifiers. And antenna gain is being increased by larger and more precise reflectors.

But one of the primary limitations to larger reflectors is the ability to manufacture the dishes and maintain them in an exposed environment to the close tolerances required. Accepted practice calls for a reflector surface accuracy of better than 1/16 the wavelength from the focal point to any point on the reflector. (For a 60′ paraboloid with a 25′ focus at 2000 mc this would mean ± 1/6″ deflection).

These extreme accuracies even put a strain on present instrumentation to measure conformance. However, **General Bronze** has devised a special microwave interferometer to measure accuracies within one-tenth of an inch.

• **Design problems**—Several other problems have had to be overcome in the design and construction of large reflectors. Wind and weather loads, for instance, are tremendous. These are compensated for in several ways: counter-balancing sails, spoilers, and even, in case of the BMEWS for example, by covering the entire structure with a 140′ diameter radome.

Goodyear has just announced a new seamless hypalon-coated nylon radome which, it is claimed, will withstand wind velocities up to 150 mph and temperatures from −65 to +135°F.

Mechanical requirements, too, impose serious problems. Tracking accuracies demand extreme tolerances in the azimuth and elevation mechanisms and the servo drives. **General Electric's** precise *Atlas* command guidance antenna requires a tolerance of 0.000050″ on the bearing race of the 2½-ton azimuth pedestal. Other parts are built to within 0.00001″. Such precision is usually found only in fine watches and delicate instruments.

It is interesting that, so far as is known, Russia has made no effort to develop giant antennas. They reportedly use a series of medium-size interconnected "orange-peel" types, similar to our height-finders, for long-range tracking and telemetry reception.

Conventional mechanical scanning systems are made somewhat obsolete in the massive antennas. Rotating the mass of a mechanical scanner suspended 25′ from the dish, for example, would require prohibitive construction to contain the vibration and moments generated.

This problem was solved neatly b **Radiation, Inc.** in the case of the 6(Atlantic Missile Range tracking an tennas by using a rotating dielectri lens in the feed system. This applica tion was used also in the modifie multi-frequency diversity feed for th Jodrell Bank antenna.

One recent development by Ger eral Bronze goes around some of thes limitations by using an entirely new ap proach. This is an improved "end-fire element array which, it is claimed, i superior in gain, lighter in weigh smaller and cheaper than equivaler parabolic reflector types. In addition, single array can contain as many a three different antennas with negligibl interaction.

The largest movable antenna in us to date is the 240′ radio telescope a Jodrell Bank, England. Several 8(parabolas are in use and 60-footers ar almost common.

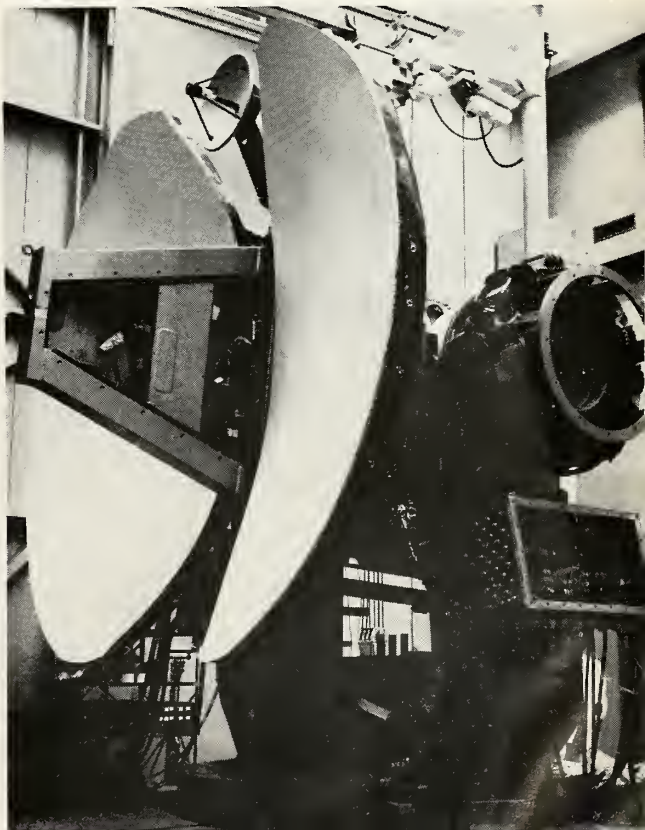
Narmco, with its "tension-truss" de sign, claims feasibility of 120′, an larger, diameter parabolas with les than 1/8″ deflection.

• **Big business**—Due to the ir creased emphasis on space communica tions, antenna design and manufactur has become a big and booming bus ness. Among the leaders in this field i **D. S. Kennedy & Co.,** which last yea did almost $14 million worth of bus ness. General Bronze reports a tota yearly volume of $10 million. **Blaw Knox's** share ran $8-10 million, an Radiation, Inc. $2 million. Goodyear' portion of the BMEWS contracts run to several million but no exact amount have been released.

Other important firms in the an tenna field include **Narmco, W. I Maxson, Philco, and Avco**—several o whom are working on classified de velopments on which no details o money amounts are available.

D. S. KENNEDY & Co.'s 120 ft. reflector swings continuously in azimuth at speeds up to six rpm.

ENERAL BRONZE's SVE tri-band tracking telemetering ntenna provides three simultaneous coincident beams on one edestal.



GOODYEAR'S BMEWS tracking antenna has spherical radome 140 ft. in diameter.

RADIATION/KENNEDY CO. TLM18 automatic tracking telemetry antenna has rates of over 7°/sec.

GE's high-precision *Atlas* tracker theoretically is accurate enough to measure an angle of one foot at 25 miles.

WESCON Trying New Method for Papers

SAN FRANCISCO—This year's Western Electronic Show and Convention—scheduled for the Cow Palace, August 18-21, promises to maintain its record as an interesting and progressive technical meeting and showplace for new developments in electronics.

Technical presentations will differ from the usual in two ways. First, each technical session will be limited to three outstanding papers in each classification. Second, each session will include a panel with several authorities on the subject being discussed plus authors of the three selected papers. The panel will comment on the papers presented, question the authors, and stimulate discussion with the audience.

Another innovation is an industrial design competition which will honor outstanding examples of electronic industrial design. Such a competition, it is hoped, will help design and packaging engineers to break away from the conventional "relay rack concept" and incorporate human engineering and visual appeal in their designs.

Not new—but unusual in such a convention—the third annual Future Engineers show will exhibit some 30 examples of outstanding work in electronics and allied sciences by high school students. These exhibits, representing nine western states and Hawaii, are selected by IRE sectional committees as the best in their respective areas. The students will compete for $2500 in scholarship awards.

To augment the technical sessions, a number of field trips to area facilities has been scheduled as part of WESCON. Selected on the basis of IRE professional group classifications, these include visits to **Dalmo-Victor, IBM's** San Jose computer center, **Hewlett-Packard, Eitel-McCullough, Lockheed, Ampex, Stanford Research Institute, Varian Associates,** and **Stanford's Biophysics Laboratory.**

A highlight for electronics industr management men at WESCON will b the annual meeting of the Weste Electronics Manufacturers Associatio The Wednesday luncheon meeting expected to attract about 350 weste industry leaders. P. E. Haggerty, pres dent of **Texas Instruments,** will be th featured speaker at the session.

An elaborate closed-circuit telev sion paging system will cover th entire Cow Palace and adjoining buil ings to carry messages and announc ments to the participants. Twelve more TV monitors will be installed i strategic locations to handle the mas ive problem of communication.

Program and arrangements for th show and convention—jointly sponsore by WEMA and the Los Angeles an San Francisco sections of IRE—ar handled by 15 voluntary committe made up of members of western ele tronics technical and business organiz tions. These committees operate und the direction of H. Myrl Stearns, chai man of the WESCON board, an B. M. Oliver, chairman of the executiv committee.

Plane-Wave Tubes Study High-Intensity Sound

ANAHEIM, CALIF.—The completion of a new series of plane-wave tubes for studying the effects of high-intensity sound on small electronic equipment has been announced by Altec Lansing Corporation. The 155-db 8-inch plane-wave tube is designed specifically to observe and determine electronic equipment malfunctioning in missiles and jets. The device is employed in establishing sensitive planes within equipment that might dictate particular mounting and location requirements. Also, support equipment, externally mounted devices, and support personnel are exposed to high-intensity noises under conditions similar to that of a free field; the plane wave tube is ide for studies of response of these el ments.

The wall of the tube confines th energy from a loudspeaker to a fr field in depth. By this energy co finement, the loudspeaker is require to generate much less energy than otherwise would have to develop establish a given energy level in a anechoic chamber.

According to Altec, these plan wave tubes are energized by compre sion type driver units. Two driver typ currently can be used interchang ably—the model 2801 high-pow unit for midfrequency testing and th model 288B driver for tests up to frequency of 15,000 cps.

ALTEC LANSING Corp. has developed a 155-db 8-inch plane-wave tube to observe and determine electronic equipment malfunctioning in missiles.

Automatic Sequencer

NEW YORK—A completely stat sequencer for control of the *Polar* missile countdown, capable of trigge ing 60 checkout operations per minut has been developed by **Magnetic Am lifiers, Inc.** of New York.

Constructed for the Missile an Space Division of the **Lockheed Ai craft Corporation,** the device is use to provide overall control of oth missile ground checkout equipment. issues its commands consecutivel compares information received in r sponse to its orders and verifies a curacy of test results.

Clustering: Big Payloads Quickly

These engines will add a greater degree of safety and reliability to manned space flight than the comparable single engine boosters

by Paul Means

WASHINGTON—The large boosters eeded to launch heavy payloads into ace during the next decade will be veloped by the technique of clus- ing.

Clustering is the method of mating isting reliable rocket engines into lger single stage with a much higher ust level. For a space program des- rately in need of larger engines, clus- ing produces the largest feasible oster in the shortest time.

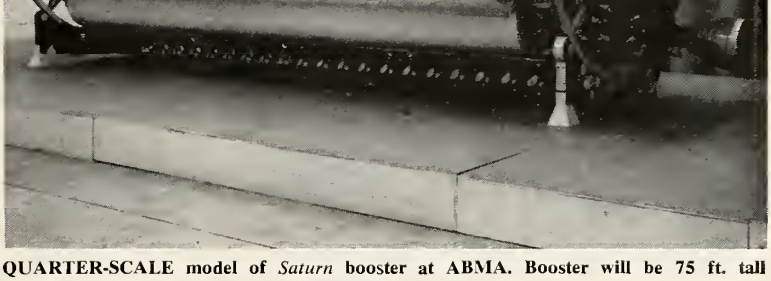
But clustering is not just a stop-gap asure. Because it can perform mis- ns or abort under guidance after lure of one or two of its engines, e clustered engine adds a greater gree of safety and reliability to nned space flight than would a com- rable single engined booster.

The concept of clustering is not w. When it became unfeasible to ild larger ship or airplane engines, ater power was produced by com- ing the efforts of more than one gine. And, as in the case of the clus- ed rocket booster, multiple engined ps and planes have a greater degree safety and reliability in that they n still operate after the failure of e engine.

• **First is** *Saturn*—The first large stered rocket engine will be *Saturn*, itiated by the Army at ABMA in rd-1958, and accepted as a project the Advanced Research Projects ency in August, 1958.

The *Saturn* booster, whose eight werful H-1 engines developed by the **cketdyne Division of North Ameri- n Aviation** will produce a combined ust of 1,500,000 lbs., has a diame- t of 22′ and a height of 5′. It is pable of boosting such sophisticated ace experiments on their way as the st-landing of a one ton payload on t moon.

Static tests of this first clustered oster will take place in December, d the first flying tests will be initiated sometime next year. The completed space vehicle, with the **Martin Co.'s** *Titan* as the second stage and a **Pratt & Whitney** liquid hydrogen engine as the third stage, could be ready in approximately two and a half years.



The eight H-1 engines are repack- aged, uprated, and simplified versions of the 150,000 IRBM engine currently in use in the *Jupiter* and *Thor*. This engine has been under development by Rocketdyne since its grandfather was used in the *Navaho*, and is also used in the *Atlas* and *Redstone*. It is the most reliable engine currently avail- able. (See M/R, July 20, page 53.)

Each engine operates independently with its own gas generator and turbo- pump. The propellant tankage is a common source for all engines. The eight outer tanks are of *Redstone* di- ameter (but not of *Redstone* length) and are clustered around the inner tank which is of *Jupiter* diameter.

Each of the eight engines operate independently, with the four outer engines movable so that they direct the course of the vehicle. They are mounted on gimbals, a part of their assembly, and have a six degree free- dom of movement on response from the guidance system.

Inertial guidance will be used, and the system will have the capability of automatically compensating for devia- tions resulting from loss of thrust should one engine fail to function. The guidance may also be able to operate step-wise shut down of the engines, allowing for a more accurate timing of first stage burnout.

• **Second is** *Nova*—The second large clustered booster will be *Nova*, whose million pound engines are cur- rently undergoing development by Rocketdyne for NASA. Initial designs cluster four of these large engines, but the payload penalty in case of an engine failure indicates that the final

QUARTER-SCALE model of *Saturn* booster at ABMA. Booster will be 75 ft. tall and 22 ft. in diameter, giving 1.5 meg thrust.

clustering: big payloads quickly . . .

configuration will use at least six engines. No firm date has been given for the completion of this booster.

The three distinct advantages of a clustered vehicle: (1) the ability to build a large thrust vehicle in a short time; (2) the reliability and safety advantages for manned flight; and (3) the great flexibility and flight control that can be maintained.

Engine development for space vehicle use operates in a cycle. The immediate need for a higher level of thrust is satisfied by clustering an existing engine of proven reliability. This can be done in a fraction of the time necessary to scale up to a single engine developing the higher level of thrust.

So a cluster of the smaller engines is used until the larger engine is developed and demonstrates a high degree of reliability. Then the larger engine is clustered, providing a booster with a higher thrust level which will be used until a still larger engine is developed, which after it achieves a high degree of reliability will be clustered . . . etc.

Therefore, at any given stage of engine development, the booster providing the highest thrust level would in all probability be a cluster.

• **More applications with cluster**—But what if it were possible to build the larger single engine in the same amount of time it took to cluster the smaller existing engines? Most rocket experts agree that the clustered engine would still have more applications because of its greater safety, reliability, and flexibility.

If, for example, one of *Saturn's* eight engines failed after launch, the following four options are available: (1) the booster could complete the mission on the seven engines with a payload that had been originally been reduced by 1/8 of full capacity; (2) the mission could be completed if part of the payload is jettisoned, (after 30 or 40 seconds of burning, the payload penalty is very small); (3) the mission can be aborted under power and guidance making possible recover of vehicle and payload (this is possible with the failure of two or more engines); and (4) the vehicle can continue into space to perform an alternate, less demanding mission.

None of the above options are available upon failure of a single engine booster. Unless the payload has an escape rocket system, both the booster and payload would be lost.

The clustered booster also achieves a greater reliability in the area of thrust decay. The characteristics of each engine may not be the same, but you can predict closer the mean value of the thrust decay of eight engines than the variance of thrust decay of one engine on a given flight. Because of this, and also the possibility of a step-wise shutdown of the engines, the clustered vehicle allows for a greater predictable accuracy from the propulsion system.

Because of the individual compartmenting of the cluster's engines, engine failures can be kept from spreading except for the rare "bomb" type of explosion.

• **Limitations**—There are limits as to how many or how few engines can be feasibly clustered. Because of the intricate relationship between the various components of a cluster, 10 or 12 engines is thought to be the largest feasible cluster. Because of the payload penalty incurred when too few engines are clustered, six is considered by some to be the minimum feasible cluster.

Saturn, whose booster clusters eight times the thrust level, must accept a payload penalty of only 12% to allow for the failure of a single engine. A booster clustering only four times the thrust level would have to accept a 25% payload penalty.

Clustering large boosters out of existing engines is not merely just clustering missiles. The parts of the missile must be fully redesigned before they go into the cluster. Many components must be reinforced because of the greater stress and pressure. Nozzles must be redesigned so that th are very short, and *Saturn's* 16 suctic lines will have to be flexible for gir balling.

Many of these problems are n within the present state-of-the-art, a must be solved through new enginee ing. The biggest problem is simplific tion of parts.

The telemetry system must have t capability of providing data insta taneously so that the vehicle aft engine failure can be kept in the m sion trajectory or switched to the abc trajectory. In a clustered engine, t guidance carries the thrust vect through the center of mass by adjusti the outer control engines.

As in all multiple fuel systems, clu ter designers must make sure that of the propellant is used up so th part of the payload does not becon unused propellant.

Clustering of the upper stages of space vehicle is slightly less desirab than clustering boosters because the is less chance of engine failure a therefore less need for multi-engine liability.

Upper stage clustering would al raise the problem of how to get f thrust from all engines instantaneous at ignition. This is done with boost clusters by clamping them down un full thrust is achieved.

• **Doubtful in solids**—Though clu tering has applications in the advanc space engines of tomorrow such as t ion, plasma, and nuclear engines, it doubtful that the principle will ev be used in solid rocketry.

One major problem with a sol cluster is that the electrical wiri together of the engines would ta place with the propellant in place. short in any of the electrical pa could mean a catastrophe.

Another problem with solid clu tering is control or determination thrust. This could be accomplished designing a grain with a small e plosive film lamination that wou rupture the propellant grain and te minate thrust. The problem with th method is that the rocket could n be restarted unless the ignition devi would also be located in the grai

The third problem with clusteri solids is that a single solid grain th could develop a million pounds thrust would probably have to be ma at the launching site because of t possibility of damage to such a lar grain during shipment.

Rapid advancements in the field solid rocketry could overcome ma or all of these objections, but prese indications are that the large space v hicle boosters of the next decade w be clustered combinations of liqu rocket engines.

AUTOMATIC TRANSLATION

Computing machines aid language research at Ramo-Wooldridge

To formulate rules for automatic language translation is an enormously subtle and complex project. Yet significant progress is being made. During the past year of research at Ramo-Wooldridge over 60,000 words of Russian text have been translated and analyzed using an electronic computer. From the beginning several hundred syntactic and semantic rules have been used to remove ambiguities that are otherwise present in "word for word" translation. Our present computer program for automatic translation is a considerable improvement over earlier attempts.

Apart from the question of translation itself, electronic computers are invaluable for language research. The expansion of existing knowledge of the rules of language, through statistical analysis, is made practical by mechanized procedures. A clear symbiosis between linguistics and computer technology has emerged.

Automatic translation research is one of many R-W activities addressed to problems of communication of scientific information. These problems are increasing at an accelerating pace. In this area, as in others, scientists and engineers find at Ramo-Wooldridge challenging career opportunities in fields important to the advance of human knowledge. *The areas of activity listed below are those in which R-W is now engaged and in which openings also exist:*

Missile electronics systems
Advanced radio and wireline communications
Information processing systems
Anti-submarine warfare
Air navigation and traffic control
Analog and digital computers
Infrared systems
Electronic reconnaissance and countermeasures
Basic and applied physical research

USW: A $4-Billion Yearly Market

Many missile companies are realizing that this great technological challenge is as important as space flight and in the next few years will be just as expensive

by The M/R Staff

WASHINGTON—Missiles are—among other things—a matter of markets. And one of the most demanding and untapped missile markets today is USW (Under Sea Warfare). It already accounts for $4-billion a year in Navy spending—including some $2-billion in direct procurement and 85% of the cost of fleet operations.

Proportionately, over the next decade the USW market will grow as much, if not more than the spaceflight market. And, that growth will draw heavily on missile, rocket and spaceflight technologies—as many companies are beginning to realize.

Though at the opposite end of the altitude spectrum, USW is every bit as important as space flight, and, over the next few years, it will become every bit as expensive. Probing the depths of Earth's oceans is no less a technological challenge than reaching up into depths of solar space. The nuclear-powered deep-diving submarine poses the same problems of closed self-sufficient environment as does the interplanetary space ship.

As an environment for missiles, the same basic problems exist: High velocity flight—200-to-300 knots; complete three-dimensional maneuverability; greater and greater operational depths (altitudes); missiles that operate entirely in the water realm; missiles that go from water to air, from water to air to surface, from water to air to underwater; underwater missiles to intercept and destroy other underwater missiles; missiles that decoy attacking missiles away from their targets; drones that are used for practice and training; unmanned advanced warning, detection and tracking units, etc., etc.

• **What USW includes**—USW now includes strategic bombardment of land targets, anti-surface ship activities (both merchantmen and military ships), and, most important of all, ASW—Anti-Submarine Warfare. In fulfilling these missions, use is made of aircraft, surface vessels, other submarines, and weapons—in being or planned. T mention a few:

Polaris, Subroc, Asroc, Weapo Alfa, Mark 37, Mark 39, and *Mark 4* torpedoes, *Regulus* I, missile min and depth charges.

However, the ocean is a strange an mysterious place. We know less abou its depths than we do about the surfac of the moon. Yet it poses as great threat to our national security as do space—perhaps even greater. And i turn, knowledge and supremacy of th oceans demands many of the sam technologies as does the conquest c space.

The submarine first started in Nav service 58 years ago. And even throug World War II it was essentially a su face vessel which could submerge t make its attack. Otherwise, it was surface vessel. Its hull was efficient o the surface; inefficient underwater. It powerplant was designed primarily fc surface operation. On the top of th sea it ran on diesel engines. Under water it ran on batteries—which ha

Market Needs in USW

—Submarines capable of 50-to-60-knot underwater speeds.

—Torpedoes and missiles able to go at least five times that fast in submerged pursuit of their prey.

—Sub-carried anti-missile-missiles to intercept 200-knot torpedoes and other high-speed ASW weapons.

—45-knot hydrofoil ships for high-speed ASW search within 200 miles of the coastline.

—High-speed missiles designed specifically to destroy hydro-foils—a kind of Hawk concept that breaks out of the water, gains altitude and then seeks the target by radar, heat, etc., from above.

—Drone helicopters that range and search and fire their ASW weapons without the benefit of direct manned control.

—Submarine-launched anti-aircraft missiles.

—Submarine-launched tactical amphibious assault support rockets.

—Anti-Polaris missiles designed to shoot down submarine-launched ballistic missiles soon after they brea through the water.

—Long-range anti-submarine weapons—includin an extended range SUBROC and adaptations of th Polaris—launch a pattern of ASW missiles just befor impact (probably employing recovery gear to slow ther down). This weapon could be fired from thousands o miles away.

—Podded Polaris and other missiles that can b anchored to the ocean floor to be launched later b remote control or by automatic sensing.

—Air and sea launched high-speed missiles tha seek out and destroy undersea craft.

—Both submarines and weapons capable of operat ing at depths of 10,000-to-20,000 feet.

—Diversionary missiles designed to draw an attack ing missile from its intended target.

—High-speed underwater drones for test, practic and maneuver.

) be charged periodically.

Today's modern submarine is nu-lear-powered, whether surfaced or sub-nerged. Its hull is designed to ignore ow-wave problems. It's faster under-ater than it is on the surface. And its nderwater speed is more than twice ne World War II's surface speed. Sud-enly it has become at home in the eep—out of its element when wallow-ng in the surface waves.

• **USW arriving in fact**—Undersea arfare has been around a long time n theory. But only recently has it nally arrived in fact. And with this rrival has come a whole new family f concepts and requirements. The rctic ice cap, once a forbidden land as suddenly become playground and nctuary.

Whole packs of submarines, either ussian or American, can lurk in eadiness indefinitely under the protec-ve layer of ice above. Where a 300-ot depth was a dangerous limit in Vorld War II, today's submarines dive adily to a depth of 1000 feet, and oats capable of operating effectively nd safely at 3000 feet are now under onstruction. Research vessels to go own three miles or more are on the rafting boards.

These are precursors of submarines nat will be at home and fight to the reatest depths of the world's oceans—hich include depths of 30,000 feet or ore, where the crushing pressure of ne waters above exceed 10,000 pounds er square inch.

Today, however, the attack capa-lities of submarines are moving ahead r more rapidly than are our capa-lities of submarine defense. For this ason the bulk of our undersea war-re efforts are devoted to ASW. Sur-ce ships, submarines, helicopters, air-anes and missiles whose sole mission to kill other subs are being bought volume. And, in turn, the Navy, ving to look ahead, is already design-g weapons to counter the weapons ey're buying now to kill subs.

But out of it all, a full spectrum of eapons emerges. Some are already thorized for procurement. (See box, larket Needs in USW) Some are tually on order. Others beg for "pro-sals with promise" from industry. ver the next decade, they add up to multi-billion-dollar market.

• **Need electronic backup**—But the rformance capabilities of these new eapons will be useless unless they ve adequate electronic backup. rgets must be detected, located, entified and tracked over great dis-nces and with great accuracy.

Currently the only operational derwater detection and tracking sys-ms rely, one way or another, on

PODDED *Polaris* **missiles that can be anchored to ocean floor and launched later are a future requirement in USW.** →

sound. And this is limited on all counts. Detection is possible at great distances, particularly with recent developments in very low frequency (below the level of human hearing) sonar equipment.

However, direction and ranging over more than a few miles are virtually impossible. Thus, so is tracking. You can tell if "something is out there," but that's about all. You don't know how far or in what direction.

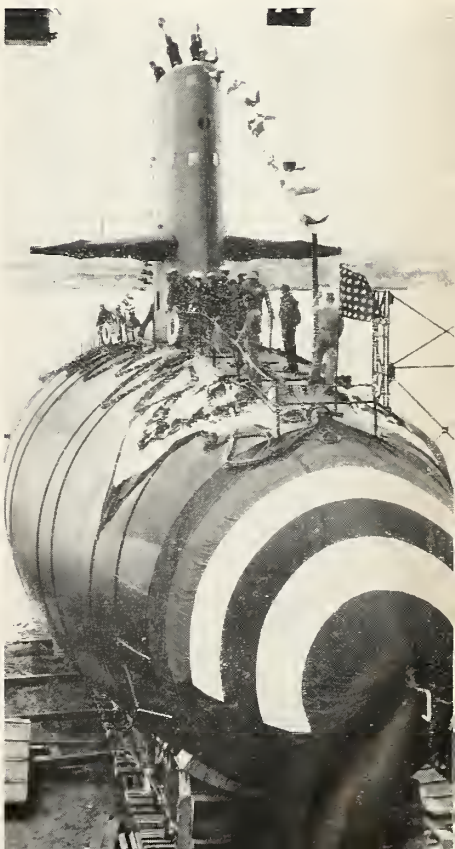
Not only that, but underwater devices are growing more and more silent. Contrarotating propellers have reduced high-speed hydrodynamic noise to a heretofore unachieved low. The French use rubber propellers to minimize transmission of engine noise—very high in fast nuclear submarines—and similar developments are believed to be underway in the U.S.

Work by **Coleman Engineering Company** on the West Coast on special boundary layer control skins for underwater vehicles has reduced drag (and cavitation noise) from fast-moving underwater bodies by 65%—with 85% theoretically possible.

• **The complaints**—A major complaint of every naval officer connected with USW is that attack capabilities are moving ahead at a far faster rate than ASW's ability to counter them. This is especially true in the realm of detection, identification, location and tracking. Underwater vehicles are becoming more silent at a more rapid rate than the range, sensitivity and accuracy of tracking gear.

A really noisy beast like the nuclear-powered submarine Nautilus on a high-speed underwater run can be heard thousands of miles away. It's a detection, but that's all. No range. No bearing.

Effective, operational detection of submarines is good only over a few dozen miles—even with the latest gear. And then, distance and direction readings are only probable—due to the ever-present salinity and temperature gradients that lace the ocean and bend sound waves over considerable angles.



Current efforts to make up for the low effective range of sonar detection take two directions:

One involves development of sonars with a greater range coupled with employment of vehicles able to cover a lot more territory in a given period of time. Helicopters, airplanes, blimps,

→

SKIPJACK, U.S.'s fastest submarine will be outmoded in a few years with the requirement for 50-60 knot underwater speeds.

USW: $4-billion market . . .

and fast surface ships such as destroyers, destroyer escorts, and various smaller ships.

Important to remember is the fact that aircraft (airplanes, helicopters and blimps) are only effective in finding surfaced or (sometimes) snorkling submarines. Their main piece of detection gear is radar. Magnetic detection gear is limited only to a few hundred yards and cannot begin to cope with the great expanses of ocean involved.

• **Hydrofoil to be funded**—Scheduled for funding during the current fiscal year is a hydrofoil—length, 115 feet; displacement, 100 tons; speed 45 knots; armament, twin ASW torpedo tubes, stern depth charge racks and twin 50-caliber machineguns—one escort research ship, a special hull configuration that is expected to do for surface ship design what the Albacore did for underwater hull design, and incorporating the latest in both long-range and variable depth sonar detection gear.

New long-range sonar is reported to have an effective range five times anything now operational. Variable depth (dunking) sonar equipment is designed to permit surface vessels to see below the thermocline—a layer of water a few hundred feet down where the temperature changes rapidly with depth-below which submerged submarines have been virtually free of detection. Presumably the variable depth sonar can be towed at whatever depths are required.

The other major approach to ASW rests in pure weight of numbers—an approach, incidentally, by which we cannot possibly afford 100% assurance of safety from underwater attack. Towards this end, however, (and this will give you a partial idea of the mounting size of this market) the fiscal 1960 Navy budget provides for two Dealy class DEs (destroyer escorts), eight ASW DDs (destroyers); one MSS (minesweeper special); three ASW submarines (Thresher class); three guided missile frigates (7500-ton displacement compared to 4000 for a destroyer)—totaling some $494.4-million for ASW ships, not including modernization of existing vehicles. An ASW submarine now under development, the Tulibee, will have a depth capability of 3000 feet.

In addition, the 1960 budget provides for 26 **Lockheed** P2V-7 Neptune ASW aircraft; 36 **Grumman** S2F Attackers; 70 torpedo and detection gear-carrying helicopters; and the first of the modified Lockheed Electra P3V-1 new-generation ASW aircraft—a total of over $400-million for ASW aircraft, if you include aircraft modernization.

Add to this some $160-million for Continental U.S. and ocean ASW sonars, radars, electronic countermeasures, etc., plus $174.7-million for ASW research, development, test and evaluation, plus a large portion of the $516-million request for procurement of ordnance and ammunition, plus nearly $300-million in ASW-related construction . . . and this market begins to take on an appreciable size.

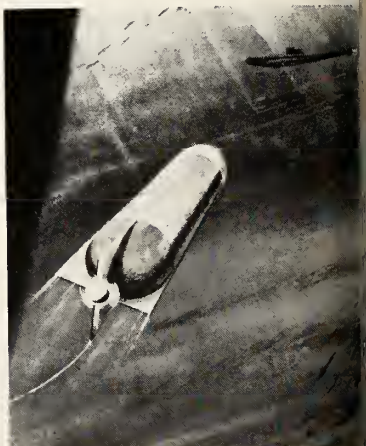
• **Capricious sound**—The only signal that man knows can travel through water is sound, and while it travels faster and farther in water than it does in the air, it is capricious at best.

In an effort to beat the limitations of sound, the Navy is spending considerable amounts of money on a large variety of underwater detection tracking and communications projects that do not involve sound phenomena.

These, lumped together, bear the unofficial title of *Project Unsound*—including efforts to find a window in the ocean for electromagnetic waves, the study of electrical phenomena, such as the motion of the ionized particles in the ocean; to see if the underwater wake of a submarine can be tracked by a homing device; investigation of both magnetic and gravitational disturbances due to the presence of metal, etc.

The cost of completely covering the coastal waters of the U.S. by present methods would be absolutely prohibitive. And, the expense of trying to patrol the oceans of the world, including those lying under the polar ice pack, would be proportionately greater. In a word, by present methods—namely, sonar—it is not possible to establish an effective anti-submarine defense. Another principle of detection capable of great accuracy and very long ranges must be developed. The Navy would pay well for such a discovery.

Meanwhile, every effort is being made to do with what's on hand. A major portion of the Navy's R&D budget is being expended on two-way communications between submerged submarines—over both close and long ranges; communications between surface ship and sub; between aircraft and sub; long range communications with shore stations.



Specifically, current effort is being directed toward further procurement and development of single sideband techniques for tactical communications between widely dispersed task force units; ultra-high-frequency double sideband techniques for line-of-sight communications; fast frequency chang equipment; ionosphere scatter; an Moon relay.

For the future, there is a windo in the ocean for infrared transmissio over considerable ranges, but which so far impracticable. Also, there tantalizing evidence of an electr magnetic phenomena that is effectiv to a considerable depth (normal atter uation of low frequency waves is som 90% in 300 feet) which is "somewh less than well understood . . ."

In a word, there are hints of breakthrough, but the "actual" has y to be achieved.

• **Computers important**—Also in portant in the ASW electronics mark are computers for firing underwat missiles at high-speed targets. Prob lems not only include calculation c firing time and angle (in three dimer sions), but en route arming, so that th torpedo's (missile's) acoustic homin device is activated only when a saf distance from the launching vessel. A example of this kind of equipment the *Mark 112* Torpedo Fire Contr System being produced by **Sperry Gy roscope** under a $12-million contract.

USW divides into two basic cat gories: Attack and defense. For th moment, attack includes standard ant surface ship operations and strategi land bombardment with ballisti *(Polaris)* or air-breathing *(Regulus* missiles. Defense includes everythin else, and accounts by far for the bul of USW expenditures. And of thi submarine detection, location, identif cation and tracking is the major prob lem. Until this is solved satisfactorily submarine destruction is an importan but still secondary problem.

MARK 39 wire guided underwater m's sile may have 60-knot speed but in 197 period torpedoes will require 200-30 knots.

• **Submarine attack capabilities**—The submarine attack capability against surface ships has improved materially in the 14 years since World War II's end. Whereas surface ships were faster (18 knots for merchantmen, about 30 knots for Naval warships vs. the submarines 12-to-15 knots short duration submerged speed), submerged submarines are now faster than most surface vessels (30-to-40 knots vs. the still-the-same 18-to-30 knots for surface ships). This means that submarines now chase, overtake and attack vessels that before they had to intercept or lay in wait for. For anti-surface ship attack, torpedoes have increased range, higher speeds and better homing guidance.

The *Polaris* system is designed to attack major strategic land targets. With its range due to increase from 1200 to over 1500 nautical miles, it is capable of attacking all of the Russian land mass except for a small 100-mile square in the Siberian heartland. A small increase in range will readily bring this, too, under potential submarine attack.

• **$612 million for** *Polaris*—In fiscal 1960, the Navy has asked for $611.6-million to support the *Polaris* Weapon system program. Of this, $220-million is for research, development, test and evaluation.

Other *Polaris* spending includes: ships and facilities, $16.3-million; servicewide operations $3-million; shipbuilding and conversion, $54-million; procurement of ordnance and ammunition, (including *Subroc* procurement for tactical defense) and military construction, $4.2-million.

Included in these figures are pipeline, shake-down and flight test for *Polaris* missiles; production engineering and tooling; special training equipment; pop-up test devices; R&D on reentry bodies, guidance, structures, controls, systems integration, command communications systems, etc.

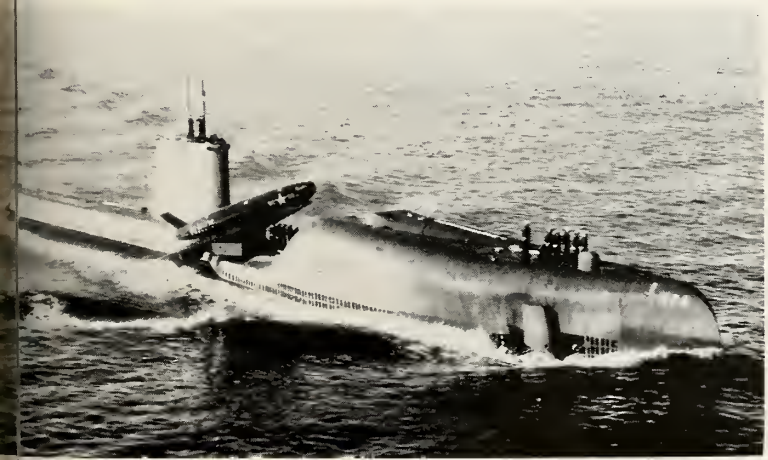
Currently there are six *Polaris* submarines under construction. Three more starts are planned during the current fiscal year, plus placement of initial orders for long lead time equipment for three more to be started in 1961. The missile itself may yet achieve operational status during 1960, as has been forecast, but only with a 1200-mile range—compared to the 1500-mile original target.

• **Assault and logistical supply**—Work is already underway on the development of undersea craft for landing troops for amphibious assault work and for the supply of overseas bases with operational essentials such as fuel, food, weapons, etc. This involves not only large troop carriers but cargo "tracker-trailers," as well. In the latter category, **Goodyear** is working on a rubber, wormlike petroleum transporter that can be towed behind a submarine. This would have practically no drag and would be almost 100% transparent to the effects of underwater blasts. In line with this is thinking and planning for undersea-launched tactical missiles to lend the same kind of close support to amphibious troops as is now supplied by aircraft.

And, as always, for every system of weapons, there must be counter-weapons. There will be a need, for example, for land troops to be equipped with effective mobile ASW weapons to fire back at this kind of underwater artillery.

• **ASW warfare** — With current technologies and physical equipment, it is not possible to spot more than a small percentage of any fleet that might be lurking off our coast. It is impossible now to detect either one or a whole fleet of atom-submarines lurking under the Polar ice pack. And even if they could be detected, they would be very difficult to attack.

It's a standard rule of thumb that torpedoes should be five times as fast as the submarine they are attacking. This means that a torpedo should have a speed of 200 knots to attack a 40-knot submarine. They need this extra speed to make up for time lost in following sound twisted and turned by ocean conditions.



Not only must it be this fast, but its self noise must not be so great as to interfere with its own sonar homing gear. Such a torpedo is a requirement still, and not an achievement. Even though the speeds have been attained using both rockets and lithium-fueled hydroducts, noise due both to cavitation (boundary layer separation) and the propulsion unit itself has made them worthless as weapons. Current West Coast efforts to develop an underwater body skin system to provide boundary layer control show some promise and may provide a partial answer to this problem.

• *Subroc* **purpose**—A major purpose of *Subroc* is to make up for the torpedo's lagging speed capabilities, as well as to extend the submarine's effective attack range. However, once back in the water on its final target run, *Subroc* will suffer from the same speed limitation as an unboosted torpedo, unless a break-through is made in quieting down torpedo propulsion or coming up with homing systems other than sonar.

Nearly everything the Navy is developing is designed to make up for the lack of range of both detection devices and weapons. The hydrofoil is designed to cover great areas in a minimum of time—like the airplane, only the hydrofoil will search with sonar as well as radar. Similarly, both manned and unmanned helicopters can cover considerable distances during a single flight, using sonar equipment dropped into and dragged in the ocean.

DD's, DE's, frigates, etc., though not capable of the other crafts' speeds can carry much heavier search equipment, which have a much greater range. The same basic approach is also true of ASW submarines, though these have the added advantage of being able to operate in the submarine's natural submerged environment. The submarine is, perhaps, the most effective ASW weapons system, and is certainly the most feared by another submarine.

And these are being designed to go faster and deeper. Current depth limit of operational submarines is about 1000 feet. Craft now on order will be capable of diving to 3000 feet. Research models are already funded capable of going down 10,000 feet and better.

SS GRAYBACK and *Regulus I*. **The 1970 submarine will have ability to launch anti-aircraft missiles and tactical amphibious assault support rockets.**

$$$—Biggest Barrier to Effective ASW

But industry hits other factors: Lack of single ASW group in Navy; lack of consistency in requirements; and difficulty in getting state-of-the-art information

by William E. Howard

WASHINGTON—Top Navy and industry ASW experts agree the biggest barrier existing today in developing an effective counter to the Soviet submarine-missile threat lurking beneath the sea is plainly—money.

Unless more basic research is funded soon—and in large amounts—there is serious doubt that the United States ever will achieve in time an ASW system capable of defending its cities from submarine-launched missiles, or keep vital sea lanes open in a limited war.

Anti-submarine techniques—particularly in the area of long-range detection—lag woefully behind rapidly advancing submarine technology. Nuclear subs, as made painfully clear by this country's own Nautilus and Seawolf, can out-dive, out-race and outsmart every ASW detection system in existence today.

What is urgently needed to close this gap are breakthroughs to new methods of detection—something which, unlike indiscriminate sonar, will home-in only on submarines and at great distances. And these breakthroughs can be achieved only at tremendous research cost.

That Congress and the Administration have failed to realize fully the scope of the problem and furnish more money dismays many persons in the ASW field. For they consider ASW equal, if not more important to the nation's security than space research. However, the chances of having ASW funds increased by any significant amounts this year or next are rather dim.

In 1959, ASW appropriations for research, development, test and evaluation amount to about $174 million. For the 1960 FY they are expected to be about the same level under the $40 billion budget ceiling.

• **Need $100 million more**—Actually, the Navy feels an additional $100 million should be spent on ASW R&D in 1960. Vice Adm. J. T. Hayward, deputy chief of naval operations for R&D, says the extra $100 million was needed this year. And for lack of it "many new ideas which were of a high risk nature have been left unfunded."

Points out Hayward: "It is entirely possible that one of these new ideas could hold the secret to a real successful improvement in ASW."

As programmed now, there may be a slight step-up in ASW R&D aimed principally at active and passive systems for detection, localization, classification and kill of all types of enemy subs—including the quiet deep-running nuclear boats. The Navy is asking for $27.9 million for sonar development and $5.2 million for oceanography. In the latter area, Russia has devoted a major part of its International Geophysical Year program.

MARK 44 torpedo, new ASW weapon, can be launched from ships or aircraft.

The Navy today feels that ASW is its prime mission. Says Rear Adm. Howard A. Yeager, acting ASW readiness executive, "ASW is practically Mr. U.S. Navy right now." It cuts across the function of practically every Navy division and bureau, from aircraft carriers to *Polaris* submarines.

Actively working on various phases of ASW is the office of the Chief of Naval Operations headed by Adm. Arleigh Burke, BuOrd, BuShips, BuAer, the Naval Ordnance Laboratory, Navy Research Laboratory and the Office of Naval Research.

But, by and large, almost all of this activity is of an operational or an applied nature that basically is no different from what the Navy was doing in World War II. As one expert puts it, "All our carriers, destroyers, blimps, submarines and helicopters today are still just as ineffective against modern Red subs as they were against German U-boats. What we need are brand new ASW techniques—and the only way to find them is through basic research."

• **Industry survey**—The Navy by saying its overall mission is ASW is distracting attention from the primary problem, in the opinion of several experts. They firmly believe that instead of allowing BuAer, BuOrd and other agencies to dabble in ASW, the Navy should set up one main ASW bureau or division to push basic research—chiefly in the all-important area of detection/identification.

Until the entire emphasis shifts to finding the answers to a foolproof detection system, the feeling in industry is that progress will be haphazard and the necessary breakthroughs won only by luck.

A confidential industry survey which will appear in the September issue of ARMED FORCES MANAGEMENT, an American Aviation publication, pinpoints these industry-Navy problem areas:

OTS-developed *Weapon Alfa* is one of the oldest ASW weapons in use y fleet. *Subroc* will largely make the weapon obsolete.

• Lack of sufficient ASW R&D unds.

• Lack of a single ASW group in ne Navy.

• Lack of consistency in Navy SW requirements.

• Difficulty in obtaining need-to-now and information about the cur-ent state-of-the-art.

• Failure to expedite field testing f R&D items.

Industry, through the National Se-urity Industrial Association, today is ying to overcome many of these dif-culties. NSIA established an ASW dvisory Committee a year ago headed y Fordyce Tuttle of **Eastman Kodak,** hich is developing infrared detection nd film data processing systems for SW. Eighty companies and more than 00 individuals—all ASW experts—re on the committee.

An NSIA official explains that the ommittee's job is basically to "make possible for industry to become ware of what is going on in ASW." he NSIA group is dedicated to pro-ding the technical assistance and in-rmation machinery to further a close orking relationship between industry nd the Navy. Problems it submits to ne Navy are in the form of recom-endations only, and it does not have ything to do with the actual placing contracts for hardware.

• **Shipboard visits** — Committee embers maintain close liasion with e Navy's "HUK" hunter-killer groups lfa and Bravo now at sea. "We go oard ship," says one, "to talk to the aman third class who is actually op-ating the equipment to find out how od it is and how it can be improved."

Chairman Tuttle spends more than 0% of his time on the move, as do any other members. All of this ac-ity is company-funded.

Major interest of the NSIA com-ittee is in the detection and classifica-n area, where a 50-member sub-committee headed by R. A. Wilson, vice president of **Daystrom Inc.,** is probing into electro-magnetic effects, environmental effects, acoustics and nuclear effects.

Other committee interests include: evaluation of sonar, wire, radio and data handling, greater depths for submarines, propulsion systems, submerged navigation, oceanographic research, weapons and fire control.

• **Company research**—Private industry long has been acutely aware of the Red submarine menace. For years —despite the lack of military funding—many companies such as **General Dynamics, General Electric, Chance Vought, Lockheed, Magnavox, Motorola, American Machine and Foundry, DuMont Laboratories, Yardney Electric, Westinghouse, Grumman Aircraft, Sparton Electronics, Acoustica Associates, ACF Industries, Goodyear Aircraft, ITT Laboratories, Western Electric, DuPont, Raytheon** and others have been maintaining ASW R&D out of their own pockets in addition to working on Navy contracts.

"They haven't been looking for profits, either," says "Red" Yeager. "These companies have made important contributions right down the line to ASW and I don't know what the Navy would have done without them.

"They have been acting as citizens —for the country's welfare. And what they are producing on their own may mean the difference in keeping the peace."

General Dynamics for some time has been moving ahead in ASW with a company-wide "task force" which is headed by Lawrence B. Richardson, engineering senior vice president. One of its divisions, Stromberg-Carlson, presently is building a $250,000 underwater acoustic laboratory.

At Lockheed Aircraft there is another intra-company ASW "task force" called LAWSO (Lockheed Anti-Submarine Warfare Systems Organization.) The company is working now on a pre-production contract for engineering design data for a model P3V-1 and holds contracts for other ASW aircraft and airborne systems.

Lockheed, whose LAWSO operation is headed by E. M. Davis, has 3700 employees engaged in ASW work —and more than 850 in ASW engineering. The company says it has devoted almost 250,000 man hours to anti-submarine operations research and more than 15 million man hours of engineering effort has gone in design of ASW aircraft.

Nearly all ASW work—from detection to weapons—is heavily classified. But some noteworthy developments have become known recently.

Vitro Laboratories, developer of the wire-guided *Mark 39* torpedo is working on a unique underwater television device *SOLARIS* (submerged object locating and retrieving/identification system) which has possible ASW detection applications. The ball-shaped apparatus is designed for retrieving missile nose cones, experimental torpedos and other objects from the ocean floor—but also might be used to sweep areas of the sea for hostile submarines.

Chance Vought reportedly is hard at work developing an advanced detection system without sonar.

A nuclear depth bomb—*Betty*—is under development by American Machine & Foundry.

At Acoustica Associates engineers are perfecting *SEFAR* (sonic end-fire for azimuth and range) acoustic transducers which will permit the design of extremely long range sonar systems at deep depths.

Grumman Aircraft now is flight testing a "futuristic" S2F-3 tracker plane, an improved version of presently operational anti-subtrackers which have hunt-kill capability in one plane.

Now operational with the Navy is the air-launched target-seeking electrically propelled *Mark 44* torpedo which was developed by GE and the Naval Ordnance Test Station, Pasadena. The Navy also recently unveiled two mines, *Mark 52* and *Mark 55*, which can be dropped from high speed aircraft.

• **What's ahead?**—Industry experts believe a big shift is on to adapt aircraft techniques to both the operation of submarines and in fighting them. Along this line, the **Electric Boat Division of General Dynamics** recently was awarded a contract to devise a submarine which would operate with a small crew. Concept may embrace the creation of whole squadrons of "fighter subs" which could patrol great areas of the sea at high speed and fight like aircraft interceptors.

Torpedoes—Neglected Factor in ASW

They'll have to be vastly more sophisticated and reliable if they are to be equal to their mission in coping with missile submarine threat

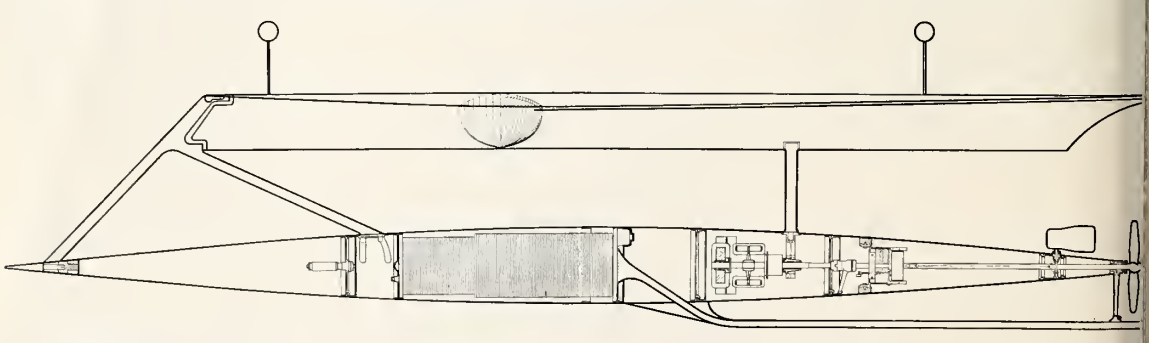
by Hal Gettings

WASHINGTON—"We forget too quickly between wars!" That's how one ranking Navy officer sums up today's widespread apathy and neglect in development of torpedoes—the first guided missiles and the number one weapon in antisubmarine warfare.

While the torpedo undoubtedly is the most universal and flexible weapon in our arsenal, their detection and running ranges must be increased. While they can be launched from the air (by blimp, helicopter or airplane), from a large or small surface ship, or from under the sea, and against either submerged or surface targets—they still must run faster and deeper to cope with future undersea targets.

First developed almost a century ago, the torpedo has progressed relatively slower than most of its contemporary weapons. Until recently, advancement has been primarily in improvement of range, speed, and accuracy.

In the last few years more significant steps have been taken with the development of rocket-powered units (*Rat* and *Asroc*) and the hybrid water-air-water missile (*Subroc*). The major effort today, however, is toward improvement in propulsion systems, target detection, and greater range and speed.



Many problems have plagued torpedo development. First, of course, has been lack of money and general apathy and neglect between wars.

• **Propulsion**—Methods for propelling torpedos have gone through several cycles of trial and error development. The first "successful" method was electric power supplied from ship or shore

CURRENT TORPEDOS

MODEL	MANUFACTURER	DESCRIPTION	STATUS
Astor	Westinghouse	Wire-guided antisub	Development
Asroc	Minneapolis-Honeywell	Antisub Rocket*	"
Subroc	Goodyear	Water-air-water missile*	"
Mark 35	GE	First production target-seeker	Operational
Mark 37	Westinghouse	Acoustic-homing	"
Mark 39	Vitro	Wireguided	"
Mark 43	Clevite	. . . . .	Obsolescent
Mark 44	GE	Antisub acoustic-homing	Operational

SIMS-EDISON TORPEDO (circa 1880)

The Sims-Edison electrical fish torpedo probably represents **General Electric's** *initial entry in the field of underwater ordnance.*

It was described as an "indestructible" copper float about 20' long, supporting a copper torpedo that varied in length from 28 to 31' and in diameter from 18 to 25". On the float's deck, two vertical rods topped by balls, flags, or lights showed the operator the path of the torpedo.

A sharp steel blade that caused the unit to dive under cables or friendly vessels protected both hull and float.

The bow section carried a 200-pound dynamite charge. The center section contained a coil of cable and the motor. Total weight was 1½-2 tons.

The torpedo was driven by an electric motor powered by a generator on shore or aboard ship through a cable 1-2½ miles long. Steering was controlled by an operator from a small keyboard. The charge could be exploded by the operator or by contact.

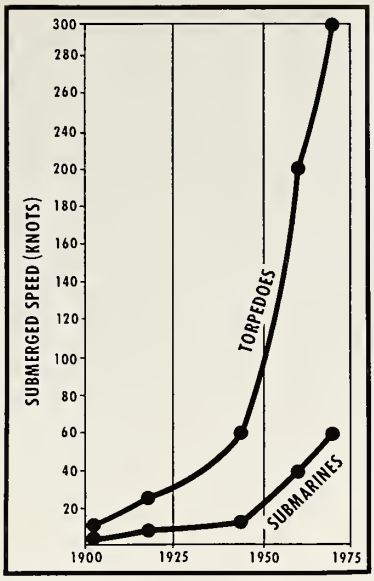
The speed of early models was 10-11 miles per hour; later units reportedly traveled at 20 knots.

The unit shown in the drawing was probably the successor to the one developed by the **Sims Electrical Fish Torpedo Company.** *Sixty tests were made on the unit in 1880 at the Army Torpedo School, Willet's Point, N.Y.*

hrough a cable paid out as the tor-
edo moved toward its target. Since
his method had its obvious limitations,
he next step was a battery carried in
he torpedo.

But the conventional lead-acid bat-
ery was found to have too many short-
omings. It didn't have enough power
nd the hydrogen gas given off pro-
ided some spectacular explosions—
ometimes even before the torpedo was
aunched. Acid splashed around during
aunching was apt to have deleterious
ffects on wiring and homing equip-
nent.

Battery, steam, and air-powered
nits all saw service during World War
I. All worked with more or less suc-
ess but had many undesirable char-
cteristics.



The problems of the lead-acid bat-
ery have already been mentioned. The
lcohol-burning steam generator and
he compressed-air types were short on
ange and long on malfunctions. Of
ourse, the availability of alcohol "tor-
edo juice" was considered by many
ubmariners to be an important morale
actor. The battery was sufficiently im-
roved toward the end of the War to
urn in an impressive record when com-
ared to the earlier score of the steam
orpedo.

Probably the greatest improvements
n batteries was the development of the
eawater battery (SWB) after WWII.
eawater, scooped into the battery after
aunch, serves as the electrolyte in
lace of acid. The battery is therefore
ry until the instant of use and poses
o problems in storage and handling.
he unit is approximately five times
s powerful and one-tenth as heavy as
n equivalent lead-acid type. It does
ave disadvantages—principally in cost
$6000-8000 each)—but is far supe-
ior to the old unit in most respects.

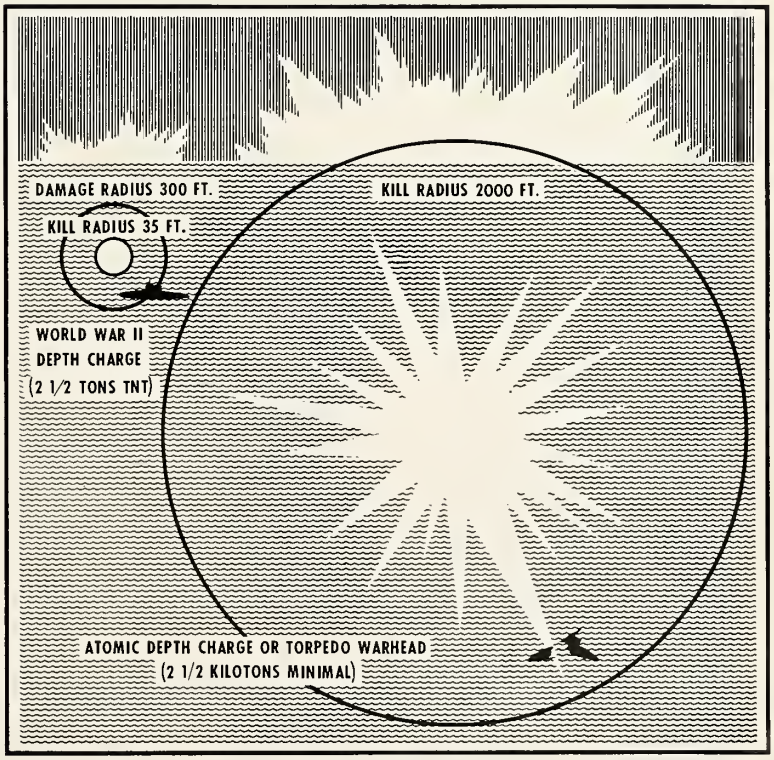
• **Rocket propulsion**—The trend to-
ay is to use rocket power for torpedo
ropulsion. Several projects using solid
ropellants are in development (*Asroc*
nd *Subroc*, for instance) but work is
o classified that no results are avail-
ble. The *Rat* (rocket-assisted torpedo)
as developed and test-fired, then
cratched.

• **Aerojet-General** has a Bureau of
rdnance contract for close to $30
illion for a torpedo development—
robably a solid-propellant type—but
ot even the model designation has
een released to date.

• **Guidance**—Torpedo guidance de-
elopment has traveled full cycle. The
ims-Edison was guided through a cable
y an operator on board the launching
hip who visually tracked the progress
f the missile toward its target. Now,
he latest operational unit—the *Mark*
9—is also wire-guided. Such a system
virtually immune to countermeasures

BASED on requirement that torpedo must be five times as fast as its target.

and evasive action.



In the interim, various types of gyro mechanisms—the first inertial guidance—controlled the torpedo on a preset intercept course. The target-seekers are guided by target noise or returned sonar echoes.

• **Dynamics and construction**—The modern torpedo is an extremely complex mechanism. It not only is a combination of systems itself, but is part of a larger and complex weapons system. It is subject to long storage, shock, extreme environmental changes, and must perform a difficult and complicated task. Reliability must be as close as possible to 100%.

Modern instrumentation methods and equipment have been an important factor in torpedo progress. Engineers can tell exactly how a torpedo has reacted and performed throughout its run and test evaluation becomes more precise. With accurate test results, areas of weakness can be improved and the entire system made more efficient and reliable.

The target seeking torpedo brought its own problems. One writer has compared the detection problem to that of trying to locate a black cat in a dark room with a rapidly-failing flashlight. The floor and ceiling are covered with mirrors at crazy angles and the walls are indefinitely located. And . . . the cat may have a flashlight, too.

• **Echo return drawbacks**—Present methods use both passive and echo-return sonar. As described in the fore-

KILL RADIUS of submarines has greatly increased since World War II when a depth charge with 2.5 tons of TNT could inflict damage to 300 feet.

torpedoes—neglected factor . . .

going analogy, however, sonar return is subject to any number of erratic conditions such as bottom or surface bounce, fish noise, temperature gradients, or other presently unexplainable phenomena. In addition, the target-seeker can be fooled by countermeasures. And, of course, there is always the possibilty that the homing torpedo may turn and attack its launcher.

The *Subroc* has a reported range of 30 miles and the *Mark 39* five miles. These distances are far beyond the effective range of sonar, however, and there is some question as to the merit of range capabality so much greater than detection capability.

Much effort is being directed toward improvement in this area, but little is known publicly as to direction and success of present research. It is generally assumed that inherent limitations of acoustic methods make necessary breakthroughs in other techniques to obtain any significant progress.

• **Future**—One company official, queried as to research in torpedo improvement said ". . . work being done to improve torpedo characteristics cannot be described in detail without giving aid and comfort to the enemy and valuable data to our competitors."

Future undersea targets are going to run faster and deeper and torpedos must be built to meet these new requirements. Detection and running ranges must be increased. Higher speeds are a necessity and better target acquisition and classification are vital.

In short, tomorrow's torpedos must be vastly more sophisticated and reliable if they are to be equal to their mission. Significant breakthroughs are demanded.

M/R SPECIAL REPORT

Soviet Subs Bigger Threat than ICBM's

Intelligence reports assume Reds converting to nuclear and deep diving boats armed with KOMET III IRBM. Red China now third biggest submarine builder

by James Baar

WASHINGTON—The Soviet submarine fleet is a gun pointed at the head of every American.

In a total war, Red submarines can smash nuclear-tipped missiles into any part of the United States without warning. In a limited war, they can reach for the jugular vein of ocean commerce that links America to its worldwide alliance.

These are considered to be the Red submarines' capabilities today. Tomorrow they are expected to be much greater.

One glance at any map of the world shows America's vulnerability to the submarine. The United States is a continental island. The front door for any all-out attack is across the Arctic. The cellar door is beneath the sea.

Soviet submarines armed with 1500-mile missiles could hit any part of the United States from beneath the Atlantic or Pacific Oceans. Top U.S. officials say it would be foolish to doubt that Russia already is capable of doing this.

Russia's specific missile capabilities aren't known. However, the Russians have had a long head start beginning in 1945 with full access to German Peenemunde plans for the *V-3* (an encapsulated *V-2* to be towed under water by submarine to enemy shores) and to data on experiments with underwater deck-launched solid propellent rockets.

The Soviet submarine fleet of some 450 boats is reported to include some 100 "W" class and some 60 "Z" class types. The big "Z" class submarines are considered capable of launching missiles from inside tubes as U.S. *Polarises* will be launched. The "W" Class is considered capable of launching air-breathing type missiles from its deck.

• **Building nuclear boats**—Russia also is reported to be building at least three to five nuclear-powered submarines. A number of them are expected to be missile launchers. And Red China has become the world's third biggest builder of submarines.

Moreover, the Russians have turned over some of their latest model subs to both China and Egypt. Also, Red submarines based in Albania may in fact have been turned over to them. This means Russia now has a number of countries to do her undersea dirty work for her in the event of any more "local" wars.

Finally, recent intelligence reports note a sharp cutback in Russian submarine building activity. The official assumption is that this is for purposes of converting to nuclear-powered craft with all their advantages of speed and underwater endurance. Simultaneously the Reds are known to be building deep-diving submarines.

All of this, combined with an effective fleet of ballistic missiles, can pose a bigger threat to U.S. security than the Red ICBMs.

• **Two series of Red missiles**—The Russians have been developing two series of missiles for their submarines. The *Golem* and the *Komet*.

The *Golem I* is a two-stage liquid missile similar to the Soviet *T-2* IRBM. Both are direct descendents of the German World II *V-2*. Its range is estimated at 400 miles.

The *Golem II* is a two-stage liquid missile with a range of 1200 to 1500 miles. The *Golem III* is a two-stage solid equivalent of the Lockheed *Polaris*. Its range is estimated at between 1500 and 2000 miles.

All three *Komets* have solid motors. *Komet I* has a range of about 100 miles. *Komet II's* range is about 500 to 600 miles, and may be capable of being fired from underwater. The two-stage *Komet III*, which is reported to be still under development, has a rang

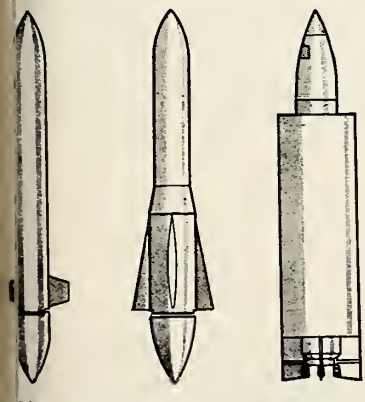
more than 1500 miles.

These weapons coupled with the ussian "Z" and "W" Class submarines ve Russia the capability of striking crippling blow against the United ates at any time.

The *Golems* and *Komets* probably ould not be used against U.S. cities it rather against bases of the Strate- c Air Command.

This is certain to be Russia's first al in any all-out war: An attempt rough surprise to catch SAC on the ound. Then DA—the Soviet inter- ntinental bombers—and the Soviet BM's would be loosed on U.S. cities d industry.

Submarines slipping through the st oceans of the world have much ore chance of reaching the North merican coasts unobserved than would viet bombers and later missiles pass- g through the gauntlet of the U.S. rctic warning nets.



Nor does the submarine threat in- lve only all-out missile attack. In y future limited war, the sea lanes the world must be kept open for e United States and its Free World lies to supply any defense effort.

Even today in the North Atlantic one 2000 merchant ships are at sea any average day of the year. An- her 16,000 are scattered in ports on the other seas of the world. Ships avelling the sea lanes to and from the nited States carry nearly 99% of U.S. overseas tonnage.

• **Would cut sea lanes**—In time of ar, the Russian submarine fleet would empt to cut these sea lanes as Ger- any did in World War II. Only, while itler began World War II with only out 60 U-boats, Russia would have ore than 450.

The Navy faces twin challenges:

• It must hit Russian submarines fore they launch their missiles.

OLEM-1 GOLEM-2 GOLEM-3

ED submarine missiles include the *olem* and *Komet* series.

• It must wreck wholesale destruction on the Soviet submarine fleet.

The principal problem is detection and identification. Once found a whole series of new weapons such as the nuclear *"Betty"* depth charge and the *Mark 44* torpedo have made the kill of a submarine not too difficult. But each year the finding becomes a tougher job.

The North Atlantic alone comprises 12 million square miles of ocean surface. The floors of the world's oceans are mostly unexplored. The enemy can hide anywhere.

In World War II, radar could be used for locating submarines when they surfaced to get fresh air and recharge their batteries. Now, only the wastebasket-size snorkel, has to be exposed. And soon the Soviet nuclear-powered subs with their ability to remain submerged almost indefinitely will be introduced.

• **Special ASW group**—The United States has designed a special hunter-killer task group to meet the challenge. The first of these is Task Group Alfa. The second is Task Group Bravo. Each group is comprised of a carrier, eight destroyers, two hunter-killer submarines, land and carrier-based planes and helicopters.

At the same time, the Navy is attempting to push forward rapidly with new means of detection from planes, ships and by the creation of some form of underwater DEW line.

In all, the United States also has 300 ocean escorts and 720 ASW aircraft at present to meet the Soviet submarine threat. It also has about 80 anti-submarine submarines—the bulk of the U.S. underwater fleet.

At the height of World War II the Allies had about 930 ocean escorts and about 2200 ASW aircraft. Germany had a maximum U-boat strength of 440—only a few less than Russia has today.

This force in time of war would strike first at the submarine ports and the narrow seas. Russian submarines would have to run a gauntlet in order to reach the open North Atlantic.

Those that made it would face the hunter-killer groups as well as the ASW submarines which include the fast *Polaris* types.

Russia might try to avoid running such a gauntlet by deploying her submarines in open water before the outbreak of war. But such a mass deployment would also carry the disadvantages of giving warning.

Of course, for an underwater missile attack no mass deployment would be necessary. Only a relative handful of "Z" Class subs could destroy much of America.

Milestones in Torpedo History

1864—*First ship (Union Sloop* Housatonic*) sunk by moving torpedo.*

1864—*Robert Whitehead began experiments*

1869—*First torpedo station founded (Newport, R.I.)*

1870—*First production units of Whitehead's torpedo (11-foot, compressed air unit. Speed 6 knots; range 200 yards)*

1872—*Electric drives first appeared*

1879—*Lay cable-controlled torpedo used by Peru against Chile. No success*

1880—*Sims-Edison electric fish torpedo developed (see sketch)*

1898—Howell torpedo, *using flywheel power and stabilization, obtained range of 800 yards and speed of 38 knots*

1903—Whitehead torpedo, *improved with a gyro and Curtiss turbine, launched (300 ordered by Navy in 1905)*

1915—*U.S. Navy began work on electric torpedo*

1917—*Germans developed electric torpedo*

1928—*Navy electric finally tested but sank in process*

1931—*Navy abandoned electric torpedo*

1941—*U.S. entered war with five types of torpedoes:* Mark 8 *and* 15 *(surface ship);* Mark 13 *(aircraft);* Mark 10 *and* 14 *(submarine). Electric torpedo work reactivated*

1942—Mark 24 *airborne target-seeking torpedo qualified and put into production. Several thousand built and credited with stopping German submarine threat*

1943—Mark 18 *battery-powered torpedo (speed 40 knots, range 4 miles) turned over to fleet where it gradually took over from steam torpedoes*

1943—*Germans began use of "intelligent" (Noise-homing) torpedo*

1945—*Work begun on "universal"* Mark 35 *(air, surface, or submarine) acoustic homing torpedo. (Modified units, less air-launch capability, went into production four years later)*

1948—*Development begun on* Mark 41, *air-launched version of* 35.

1950—*Work begun on lightweight, small, target-seeking* Mark 43

1958—*Wire-guided* Mark 39—*an "underwater guided missile"—introduced*

1959—*Surface or air-launched* Mark 44 *introduced.*

Servovalves Need Fresh Approach on Temperature

Moog Valve believes 1000 F reachable by using acceleration switching servos

by Jay Holmes

EAST AURORA, N. Y.—How would you like to be the largest stockholder in a company that doubles its sales every year?

William C. Moog, a development engineer formerly with Cornell Aeronautical Laboratory in nearby Buffalo, was in this happy position from 1951 until 1957. His **Moog Valve Co.,** now **Moog Servocontrols Inc.,** had $200,000 sales in its first year and approached $9 million six years later. After a recession dip in fiscal 1958, the company set another record of more than $10 million in the year ended June 30.

Moog, while employed by the Cornell Lab, invented an advanced and sophisticated servovalve of a type requested by the military for service in the rugged environments anticipated for guided missiles. When **Bendix** ordered four of the valves for use on a defense job, the lab gave Moog the order. The Cornell lab is set up for research alone and is not interested in production contracts.

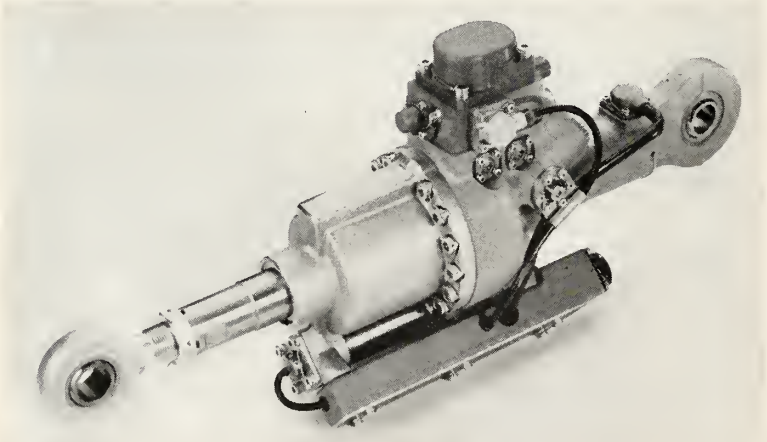
• **Manufacturers decline**—He inquired of several manufacturing companies but none of them thought the market was large enough for them to go into it. And so he decided to take six months' leave and do it himself. Moog found a machine shop willing to make the valves and to wait for its money until Bendix paid. The first valves were assembled in his basement.

At about this time, **Philco** ordered 75 units for $30,000. With this encouragement, Moog decided to incorporate. He has never had reason to regret it. The market has been growing steadily almost all of the time since then.

What is a servovalve? It is an automatic error-correcting device for critical flight applications, foremost of which is controlling the flight of aircraft and missiles. When the attitude changes from that prescribed, an electronic sensor transmits the change to the servovalve, which then adjusts the flow of oil through an actuator po tioning a control surface or engi Sophisticated controls of this type fi became necessary when aircraft spee reached the neighborhood of that sound and it was no longer possib for human pilots to make correctio fast enough.

After a while, Moog began man facturing servoactuators which cor bine the valve, cylinder and feedba device in one mechanism.

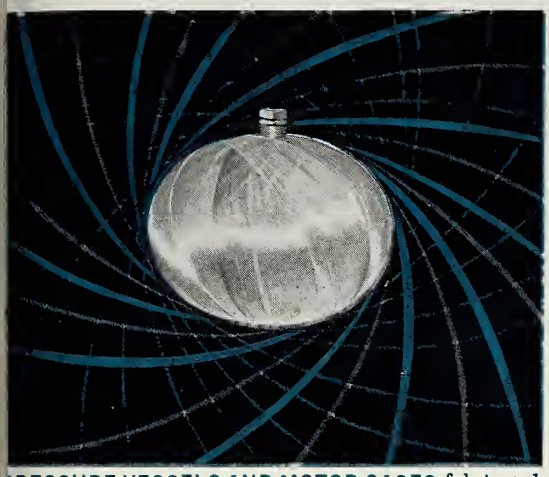
Missile and aircraft servovalves a incredibly small for the work they pe form. The first Moog valves weigh about a pound, with dimensions about 2″x2½″x1½″. Later mod have been reduced to about a ha pound. William Thayer, Moog's chi engineer, says a servovalve has two di tinctive features: high power contr from a low power signal and contin ous control that can change the dire tion of output in two directions. Th contrasts with a thermostat, for e ample, which can increase temperatu but cannot decrease it.



• **Musical valves**—A servoval can accept an input on the order 50 milliwatts and regulate an outp of many horsepower—a power gain the order of 10^7. It acts rapidly, a most as fast as an electric current. Th signal from a phonograph needle ca be fed into a servovalve and somethi recognizable as music will come out.

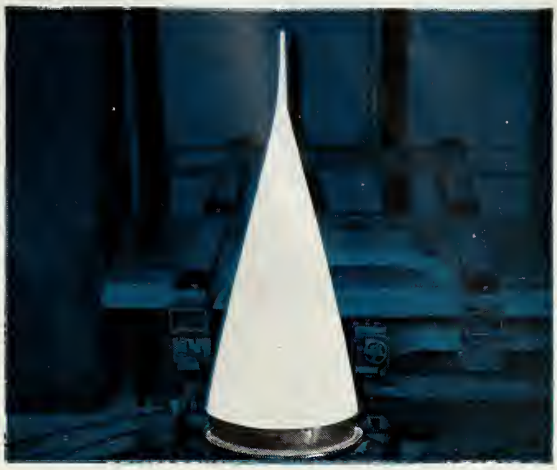
Servovalves in use at present w operate within a temperature range –65° to 500°F. The most importa new requirement is for an increase i the upper temperature limit. Models i development will bring this to 700°F but Moog says a fresh approach needed for an attack on the next ten perature barrier, 1000°F.

One possible solution is the use acceleration switching servovalve Basically, the difference between suc a valve and the earlier types is tha the valve force motor operates on simple on-off basis, rather than b graduated variation of signal strengt

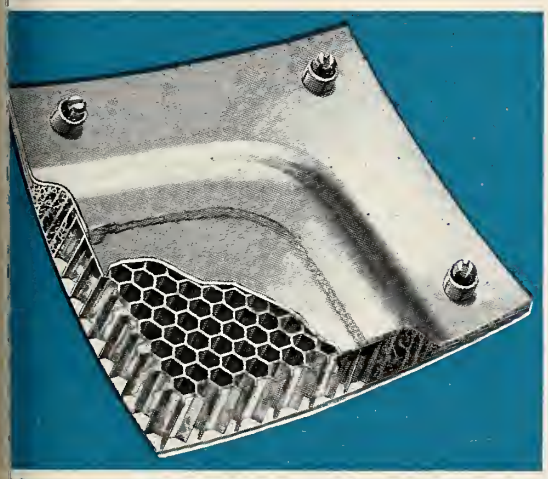


Under such an arrangement, elec trical hysteresis does not affect opera tion and it is possible to use plain cold rolled steel for the motor magnetic cir cuit. Theoretically, it would be pos sible to operate a switching valv motor to temperatures well abov 1000°F—possible to almost 1400°– with acceleration switching.

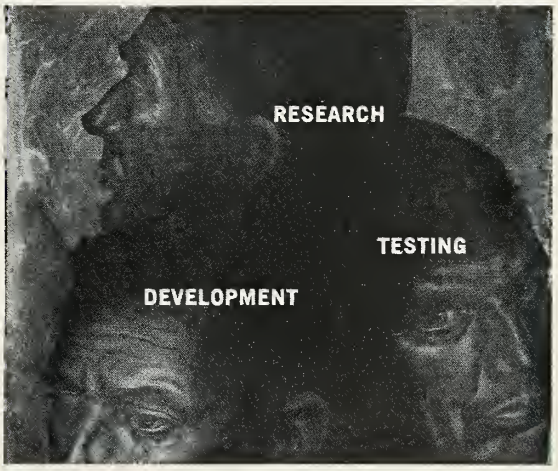
On a rocket, servovalve system are used to actuate control surfaces on-off switching of control engines an thrust-vector controls. With a four nozzle solid-fuel engine, adjustment o the four can control pitch, roll an yaw. With a single-chamber liquid-fue rocket, this is accomplished by swivel ing the entire engine.



TINY SERVOVALVE can accept input near 50 milliwatts and regulate an output of many horsepower—a power gain on the order of 10^7.



Brunswick technology leads the way in three critical space-age components



PRESSURE VESSELS AND MOTOR CASES, fabricated by Brunswick's exclusive Strickland "B" Process, now have the highest strength-to-weight ratio ever obtained in filament-wound components. Brunswick is *now* producing these virtually leak-proof pressure vessels. Brunswick also fabricates motor cases capable of withstanding extremely high pressures and temperatures.

RADOMES AND NOSE CONES, created by Brunswick's outstanding research and development efforts and filament winding process, are being used on supersonic aircraft such as the advanced Convair F-106 and McDonnell F4H, as well as on missiles such as the Boeing Bomarc, Lockheed Q5 and similar missiles. And, of course, Brunswick capabilities include complete electronic design and test facilities.

HONEYCOMB ASSEMBLIES, now developed by Brunswick can support two million times their own weight. Brunswick research has created honeycomb assemblies of paper, fiber glass, aluminum and stainless steel as well as conventional forms. Using the most advanced adhesive systems, these assemblies can be formed in compound curvatures with extremely close tolerances.

RESEARCH, DEVELOPMENT AND TESTING—carried on by Brunswick teams have contributed heavily to space-age technology . . . most notably in solving problems of increasingly high operating temperatures (600°—4,000°F.) for critical components and new heights in strength-to-weight ratios. For full information on how this leadership can help you, write or call Brunswick today!

RELIABILITY

is what determines the success or failure of any weapon system at launch and during flight. Here at the Missile Division of North American Aviation, we are constantly striving to improve this most vital state of the art through analysis and evaluation of environmental criteria, system design analysis, statistical test programs, and other advanced reliability techniques. Engineers and statisticians with a minimum of five years full time related experience in aircraft or missile engineering will find this a most stimulating career in present and future efforts under development.

missile support

Air-Supported Space Platform Is Advocated

ARTIST'S conception of air-supported space platform structures.

BUFFALO—The first space platform will be an air-supported structure, a Buffalo manufacturer predicts.

Walter W. Bird, president of **Birdair Structures Inc.,** maintains that light weight, portable plastic housing is ideal for the first habitable satellite, since the rockets carrying such materials into orbit will have very small payloads.

The housing could be built in units carried into orbit on successive flights, Bird said. Air could be carried up in liquid form and boiled into the structure to inflate it.

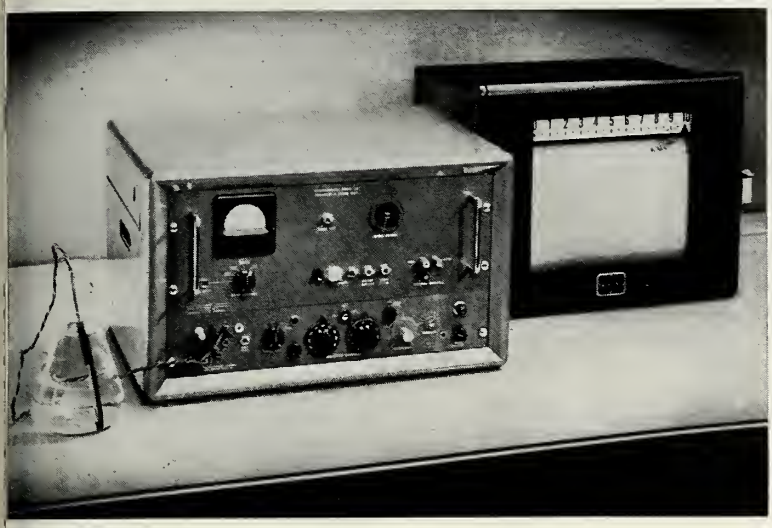
Bird is well qualified to discuss the building of large, inflatable plastic structures. His company manufactures the Pentadome, a missile maintenance shelter 150′ in diameter and 85′ high with four smaller auxiliary domes, for the Army. The Pentadome maintains its shape without rigid supports, poles or frames—just with constant low pressure, high volume air supplied by motor driven blowers.

The center dome of the Pentadome consists of five sections that have to be joined together. This makes it easier to handle the dome in erection, dismantling, packing and shipping operations. However, Bird said it would be possible to make a housing in one piece for space use.

Many types of material are used in Birdair structures. The Pentadome consists of 18,000 square yards of vinyl-coated nylon. The central dome material weighs 24 to 25 ounces per square yard. The smaller domes, 100 in diameter and 50′ high, weigh abou 18 ounces per square yard. The struc ture is designed to withstand a con stant wind load of 70 miles per hour It has a safety factor of 3 to resis gust loads of greater velocity. Th fabric is designed to retain its flexibil ity at –40°F. The material is designe to carry full loads up to 160°F.

What about meteorites and micro meteorites in space? Bird asserts tha a resilient plastic material will with stand such blows better than rigi structural materials. Some particles tha would penetrate a firm jacket, he says would bounce off or be absorbed by resilient material.

The Pentadome, which stands 8½ stories high, can serve as a protectiv cover for a *Jupiter* missile while it i being readied for firing. Smaller plasti covers are used to protect other mis siles. In come cases, a missile is fire after a quick release, sometimes on th order of 1½ seconds. In other case the missile is fired through the dom



Bethlehem Research Center Going Up Despite Strike

BETHLEHEM, PA.—Foresight i stocking structural steel has enabled contractor to maintain construction o a **Bethlehem Steel Co.** research cente despite the steel strike.

Turner Construction Co. of Ne York is the general contractor for th multi-million-dollar center for metal research and development. The firs buildings are to be completed nex year.

Bethlehem is building the center o a 50-acre site high atop South Moun tain in Bethlehem, near the campus o Lehigh University. When it is complet several years from now, about 40 will be employed.

The center will provide facilities fo work in process metallurgy, mechani cal engineering, physical metallurg mechanics, chemical engineering ceramics, chemistry, physics an nuclear engineering.

Corrosion Now Measured Automatically

Automatic corrosion measurements are now possible, using a new servo-controlled corrosometer manufactured by **Crest Instrument Div., Magna Products, Inc.**

The Model L-2 corrosometer is capable of detecting as little as one millionth of an inch of corrosion on a routine basis and one billionth of an inch in some special applications. It automatically "tracks" corrosion as it occurs, providing a permanent record of the total thickness of metal corroded. This record is presented as a function of time which is quickly converted to the rate of attack.

In the laboratory, the Model L-2 corrosometer greatly simplifies the job of evaluating the effects of corrosion inhibitors on the resistance of various metals to known corrosive conditions. The pattern of corrosion differs from metal to metal, and the Model L-2 eliminates the tedious, point-to-point plotting required when the timing and extent of the initial attack is unknown.

A single Model L-2 may be used to monitor up to twelve individual tests by adding additional measuring units. A single multipoint recorder can be used to record data from these tests being run in parallel at the same time.

The Model L-2 also finds use in oil refineries and chemical plants, where it detects the change in corrosion rate resulting from the addition of inhibitors or from changes in process conditions. The effect on the corrosion rate may be immediate, or it may extend over a long period, and again the Model L-2 saves time and trouble over point-to-point plotting.

In the case of inhibitors, the instrument may be used to evaluate various proprietory compounds under actual plant conditions, or it may serve as part of the plant's basic instrumentation system, telling operating personnel exactly when corrosion has reached a dangerous level and new inhibitor should be added to the process stream.

Like other corrosometer instruments manufactured by Crest, the Model L-2 detects corrosion by measuring the ratio of resistance between exposed and protected metal elements mounted on a "probe" that extends into the corrosive medium or sample. As the exposed metal is corroded, the resistance ratio between the two elements increases. This increase is a direct indication of corrosion. Since both elements are mounted together, resistance changes due to temperature fluctuations have no effect on the readings.

In the Model L-2, the two metal elements in the probe form two legs of a bridge circuit, with a servo-driven potentiometer acting as the automatic balancing mechanism. The position of this potentiometer is a direct measure of corrosion. The gear train connecting the servo motor and the balancing potentiometer also drives the recorder output potentiometer.

The tracking "range" of a probe is typically divided into one thousand corrosion units, each unit being one microinch. Corrosion totalizer dials on the face of the instrument indicate how many micro-inches of corrosion have occurred. The recorder, on the other hand, swings full scale with only 10 microinches change, thus providing a high level of resolution.

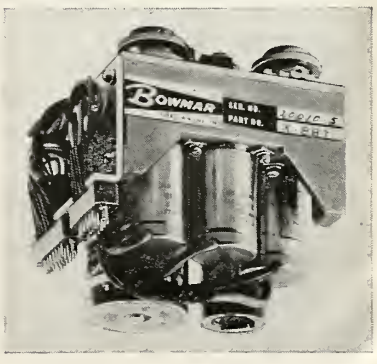
Miniature Servo Picked for *Pershing* Guidance Unit

The heart of the inertial guidance system for the new Pershing IRBM—a miniature servo-package—will be produced by the **Bowmar Instrument Corporation.**



Edward A. White, Bomar president, said that the firm has been awarded $65,000 in contracts for the manufacture of an initial order of the units.

The new unit is a program transmission servo-package which plays a key role in the ST-120 air bearing gyro stabilized platform. It transmits tilt program pulses from a programming tape to the Pershing steering mechanism, in a smoothly changing voltage, that corrects for course deviations.

To meet size and weight requirements, Bowmar engineers had to reduce the package to one-third of its standard dimensions, producing a package 2½ x 2¼ inches and weighing less than 34 ounces.

Housed in the package are essentially two systems, each performing a function in the overall control and guidance of the missile. The first system consists of a stepper motor, dual cams and microswitches, synchro control transmitter and gear train. It ultimately indicates the position of the synchro control transmitter of this first system via a signal proportional to its shaft angle.

The second system of this assembly consists of a motor rate tachometer, synchro control transformer, synchro control transmitter, one dual and one single cam and microswitch together with separate gear trains between the motor tachometer and first synchro, the first synchro and the dual cam-

Expanding the Frontiers of Space Technology in

SYSTEMS ANALYSIS

■ Lockheed Missiles and Space Division has complete capability in more than 40 areas of science and technology. As systems manager for such major projects as the DISCOVERER Satellite; Navy POLARIS FBM; Air Force Q-5 and X-7 and Army KINGFISHER, the Division is extensively engaged in improving the art of systems analysis and integration.

ENGINEERS AND SCIENTISTS

The Division's programs reach far into the future and deal with unknown and stimulating environments. It is a rewarding future with a company that has a continual record of progress and achievement. If you are experienced in one or more of the following, we invite your inquiry: classical dynamics, vector analysis and matrix operations, with the ability to establish and analyze weapon systems performance; inertial guidance systems; dynamics of missiles systems; or long range ballistic fire control systems. Ability to prepare and edit technical reports documenting results of systems analysis studies is a requirement.

Write: Research and Development Staff, Dept. H-1-29, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship required.

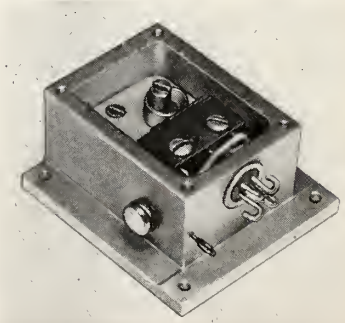
microswitch and the second synchro and the cam-microswitch. From the second synchro to the single cam-microswitch is 1:1 gearing. This second system ultimately indicates the position of the synchro control transformer and transmitter.

Backlash between synchro control transmitter and synchro transformer of the second system portion measured at the synchro control transmitter of the first system is 3 minutes maximum. Backlash between the motor and the synchro control transformer is 30 minutes maximum. Basically, four different gear reductions are included in the entire package. Reduction between the stepper motor and the synchro control transmitter is 9:1 and reduction between the motor rate generator and synchro transformer is 100:1. Reduction from the synchro transformer of the first set of cams and microswitches is 3:1 and reduction from the first set of cams and microswitches to the synchro control transmitter is 40:3. A ratio of 1:1 exists from the synchro control transmitter and the single cam and microswitch.



The housing of this package is of clean anodized aluminum and bearings are ABEC Class 5 or better. Gearing tolerances are Class 2 or better. The entire unit is designed for operation in ambient temperatures of −55°C to +100°C. Unit construction was designed to withstand environmental conditions as generally specified in MIL-E-5272.

Tiny Mechanical Timer Weighs Less Than 4 oz.

The nation's smallest mechanical timer (fits into 1 cubic inch of space) is now in production at **Timech Corp.**

Weighing less than 4 ounces, Model TMC-50 timers are available over a time range of 1 to 20 seconds with accuracies of 3% and 5%. Designed primarily for use on missiles and target drones, the new mechanical timers are used as events programmers and timers, and to release recovery parachutes.

An unusually rugged device, capable of withstanding all of the environmental hazards of missile operation, the new Timech timer performs its function with extreme reliability. It is engineered to perform reliably in ambient temperatures from −65°F to +250°F; Shock of 300 G's-millisecond duration, and vibration of 25G's from 25 to 2,000 cps. The Model TMC-50 mechanical timer is also built to meet the standards of MIL-STD. 202 and MIL-E-5272A.

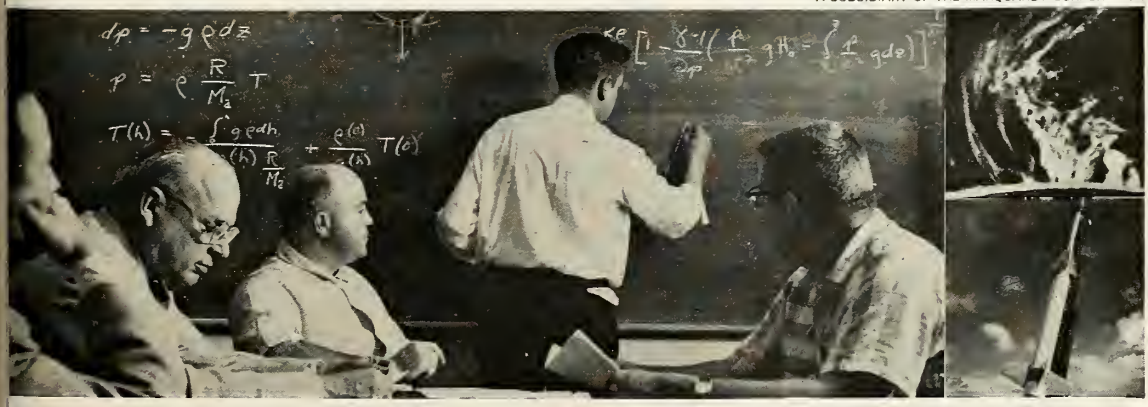
Delay Relays Feature Adjustable Timing Ranges

Two new lines of time delay relays, with guaranteed accuracy ratings of 10% to 5%, have been announced by **Tempo Instrument Inc.**

These units are said to be the only known adjustable time delay devices that meet all the accuracy and reliability requirements of high performance electronic systems, particularly for airborne and ground support missile applications.



The new Tempo units, of subminiature size and weight, include provision for simple, quick field adjustment of the time delay period. Adjustment may be accomplished with a precision potentiometer located remotely from the unit, or with a stable fixed resistor wired directly across the terminals provided on the unit. A standard calibration table is supplied showing the resistance value required to result in a given time delay period.

Six basic units are available, with overlapping time delay ranges—each is capable of a 20 to 1 adjustment range as follows: .050 to 1.00 seconds, .5 to 3.00 seconds, .750 to 15.0 seconds 3.00 to 60.0 seconds, 9.00 to 18 seconds, 15.0 to 300 seconds.

By stocking only 6 units, the user has immediately available a wide range of highly accurate time delays, from

Southern California opportunity for creative rocket systems scientists, engineers. CDC's current expansion has created several key openings. Specialist in complete rocket systems, CDC offers you opportunity to join the team that has helped orbit America's satellites...to contribute to upper-atmosphere and space research programs like Explorer, Vanguard, Sunflare, Eclipse and Project Mercury. Rewards are high if you can generate original ideas and take responsibility on your own shoulders. A subsidiary of The Marquardt Corporation, CDC assures you outstanding career stability. High-level Engineering Writer. Capable of assuming responsibility for creative engineering writing on preliminary design concepts. Aerodynamicist. B.S. in A.E. Familiar with drag prediction in subsonic and supersonic flows. To perform drag and stability analyses on rocket motors. Physicist. Ph.D. or M.S. preferred. Experienced in research and analytical studies in upper atmosphere physics. Knowledge of meteorology helpful. Instrumentation Engineer. B.S. in M.E., E.E. or physics. Experienced in development of instruments and instrumentation systems. Electronics Engineer. Experienced in transistor theory, instrumentation, and telemetering systems. Project Engineer. B.S. in physics, M.E. or A.E. Familiar with sounding rockets, aerodynamic heating problems and stress. Experienced in organizing a project. Senior Systems Analyst. M.S. or Ph.D. To head group. Experience in propulsion, guidance, instrumentation, aerodynamics, thermodynamics preferred. Senior Mechanical Engineer. To head mechanical development group. Experience in rocket vehicles, mechanical auxiliaries, ground handling equipment, and rocket launchers desirable. Systems Engineers. B.S. or M.S. Broad systems knowledge. .050 to 300 seconds in missile testing and checking operations.

The rated accuracies, either 5% or 10% of nominal time delay, are guaranteed under any combination of environmental and operating conditions including input voltage variations from 18 to 31 vdc, temperatures from −55 to +125°C, vibration to 20 g's, 2,000 cps., shock to 50 g's, 11 milliseconds, acceleration to 20 g's.

Circle No. 228 on Subscriber Service Card

Accuracies of .025% Provided by Transistor

The Abrams Instrument Corp. has announced the development of transistor, crystal controlled dc inverter to 400 cycle ac output with frequency accuracy of .025% through a temperature range of −60°F to +165°F.

The time base comprises a crystal controlled oscillator, transistor divider and output amplifier. For even greater accuracy, the unit can be furnished with a crystal oven at slightly higher cost and current requirement. Dip potted, the unit withstands high acceleration, vibration and shock. Input dc

voltage can vary as much as ±25%.

Encapsulated in a dustproof stud mounted relay case approximately 1 9/16 x 1 3/8 x 2 1/8; the inverter weighs approximately 4½ oz., and has enough power to drive a synchronous motor with a .002 inch oz. torque. By increasing the power amplifier at some sacrifice in size, larger torque motors or multiple synchronous motors can be used with the same accuracy of output.

The Model DB-1 time base for a synchronous motor, makes possible a multitude of applications in the airborne timing and control field where only dc voltage or unregulated ac is available. The advantages of extreme accuracy (.025%), no radio noise interference from motor brushes to filter, extreme environmental capability and maintenance free motor life, (well over 10,000 hours); are the answers to previous major design problems.

New Comparison Bridge Model Features Simplicity

Southwestern Industrial Electronics Co., a division of **Dresser Industries, Inc.**, has announced the introduction of its new-series model E-2 Comparison Bridge.

A replacement of a previous SIE model of the same number and type designation, the new model is said to encompass ranges from 1 ohm to 5 megohms resistance, 500 mmf to 2000 mf capacitance and 3 milli henrys to 10,000 henrys inductance at accuracies from 2.5% to 0.1%.

Advantages of the new model are said to be increased accuracy, a reduction of component selection time, minimal operator fatigue, a simplicity which allows unskilled operators to obtain 0.1% accuracy and to detect component differences as small as one part in ten thousand.

"Multi-Zone" Platecoil Cuts Heat-Up Time 17½%

Improved performance resulting from a change in product design has been proved by **Tranter Manufacturing Inc.**, in a test of its new multi-zone platecoil heat transfer unit under actual operating conditions.

The test was performed in a rinse tank at the **Ideal Finishing Co.**, where the original header-type Tranter platecoil had been used for several years for heating up the water in the rinse tank. The tank has 600-gallon capacity and the desired operating temperature is 200°F.

With steam at 15 psi, the old style platecoil heated the water from 60°F to 204°F in 182 minutes. With the same steam pressure, the multi-zone platecoil heated the water from 60°F to 203°F in only 150 minutes—a saving of 32 minutes, or more than 17½ percent faster, to reach the desired temperature.

The tests were run under identical conditions, with the old coil being removed from the tank after the first test and the multi-zone platecoil being placed in exactly the same position.

The units are two embossed sheets of metal, welded together to form channels for the passage of heating or cooling media, such as steam or water. In the old style header platecoil, one common header extended the width of the unit, feeding all of the lateral passages that carried the steam across the unit to the common condensate return.

In the multi-zone platecoil, the steam inlet header is divided into three branches so that steam is carried directly to all areas of the platecoil simultaneously. In effect, the new unit provides three platecoil units in one.

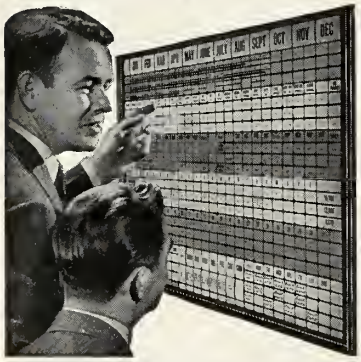
Oil-Damped Transducer Withstands Rocket Blast

Statham Instruments, Inc., announces the P285TC miniature pressure transducer developed for use in rocket engine test environments.



Because it is oil-damped, the P285TC withstands the violent pressure transients generated in shock tubes or transmitted from firing chambers. In addition, the high natural frequency of undamped miniature flush-diaphragm instruments is retained.

The P285TC measures pressure from 0-50 to 0-1000 psi with the operational, environmental and service life advantages of unbonded strain gage transducers. Case length: 49/64". Width (between hexagonal sides): 1.0". Weight: approximately 3 ounces.

Output approximately 28 millivolts full scale open circuit at 7 volts (AC or DC) excitation. Non-linearity and hysteresis not more than ±1% of full scale.

propulsion engineering . . .

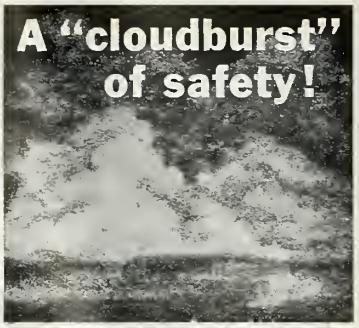
By M/R STAFF

Liquid oxygen-ozone mixtures . . .
containing up to as much as 30% ozone can be safely used as a rocket engine oxidizer for gaseous hydrogen if the temperature is controlled properly. National Aeronautics and Space Administration researchers have used the combination successfully in carefully-designed engines, and have determined the limits of brisant detonability. Riley O. Miller of NASA's Lewis Research Center, Cleveland, described O_3-O_2 experience to the American Rocket Society's propellant thermodynamics and handling conference in July.

Ozone handling apparatus and procedure . . .
can now be specified for many use and handling situations, thanks to Miller's work. He attempted detonations of ozone-oxygen in various sizes and shapes of stell and glass tubes. Some were triggered by an initial pure ozone detonation, others by direct spark. The degree of fragmentation was one measure of brisance. Miller reports that a steady-state Chapmen-Jouguet detonation propagates from a spark in liquids containing 50% to 100% ozone. From 50% down to about 35% ozone (by weight), it is still possible to achieve detonation if it is initiated by a 100% ozone booster charge. At 35% or less ozone, no brisant propagation is obtained.

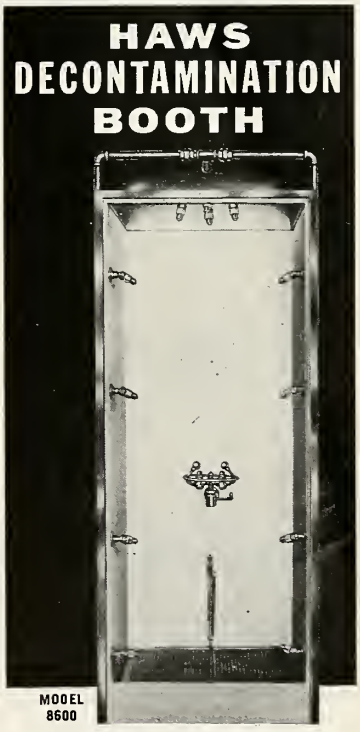
Safe mixtures may not stay safe . . .
if they are improperly handled, Miller points out. The biggest ozone handling worry is that, due to O_3's physical properties, ozone can be concentrated inadvertently. Miller points out these three ways this can happen:

(1) High concentration liquid ozone may condense from a dilute gas.



(2) Dilute liquid ozone may lose some of its diluting oxygen if the temperature increases.

(3) There is a two-phase region which is dependent on temperature and composition of the liquid mixture. In this area, the liquid separates into two phases, one more concentrated than the other.



Propellant tank was mixing bowl . . .
in the NASA experimental ozone rocket. "The required liquid O_3-O_2 mixture was prepared directly in the propellant tank," Miller reports. "Specially purified oxygen was passed through a specially cleaned ozonator . . . into the bottom of the refrigerated propellant tank where the ozone and all or part of the oxygen were condensed." All components that contacted the mixture were refrigerated. Liquid nitrogen was used when the ozone concentration was to be only 2%, but liquid oxygen was used as the refrigerant when higher ozone concentrations were used.

Few unexpected problems came up . . .
when Miller ran the engine. Runs were 3-seconds each, with continuous spark ignition. Miller found that the oxidant inlet valve should not be refrigerated when *gaseous* ozone-oxygen was passed through. Small amounts of ozone would condense on it and detonate, breaking up the Teflon packing. The result was leakage and Teflon fragments in the system.

A brisant detonation occurred . . .
in the line between the oxidant control valve and the oxidant tank at the start of one run. Tubing and flowmeters were fragmented, Miller says. Heavy forged valve bodies were split. The refrigerant trough was torn into several pieces and scattered "with considerable velocity." Miller says the detonation appears to have been initiated by a low energy source, away from the rocket combustor. That explosion, Miller says, emphasizes the need for careful consideration of all operations before they are tried.

Volatile chemicals and propellants can cause serious accidents—but serious injuries need not result if water irrigation is immediately available! Haws Decontamination Booth provides the "cloudburst" that rapidly rids the body of harmful irritants. Victims walk on the foot treadle and are instantly bathed in water from a dozen nozzles. Haws Eye-Face Wash is simultaneously activated—a pressure controlled unit with a perforated face-spray ring and twin eye-wash heads. Booth is acid resisting fiberglass plastic, and is delivered complete, ready for tie-in to existing facilities. Write for details on the full line of models.

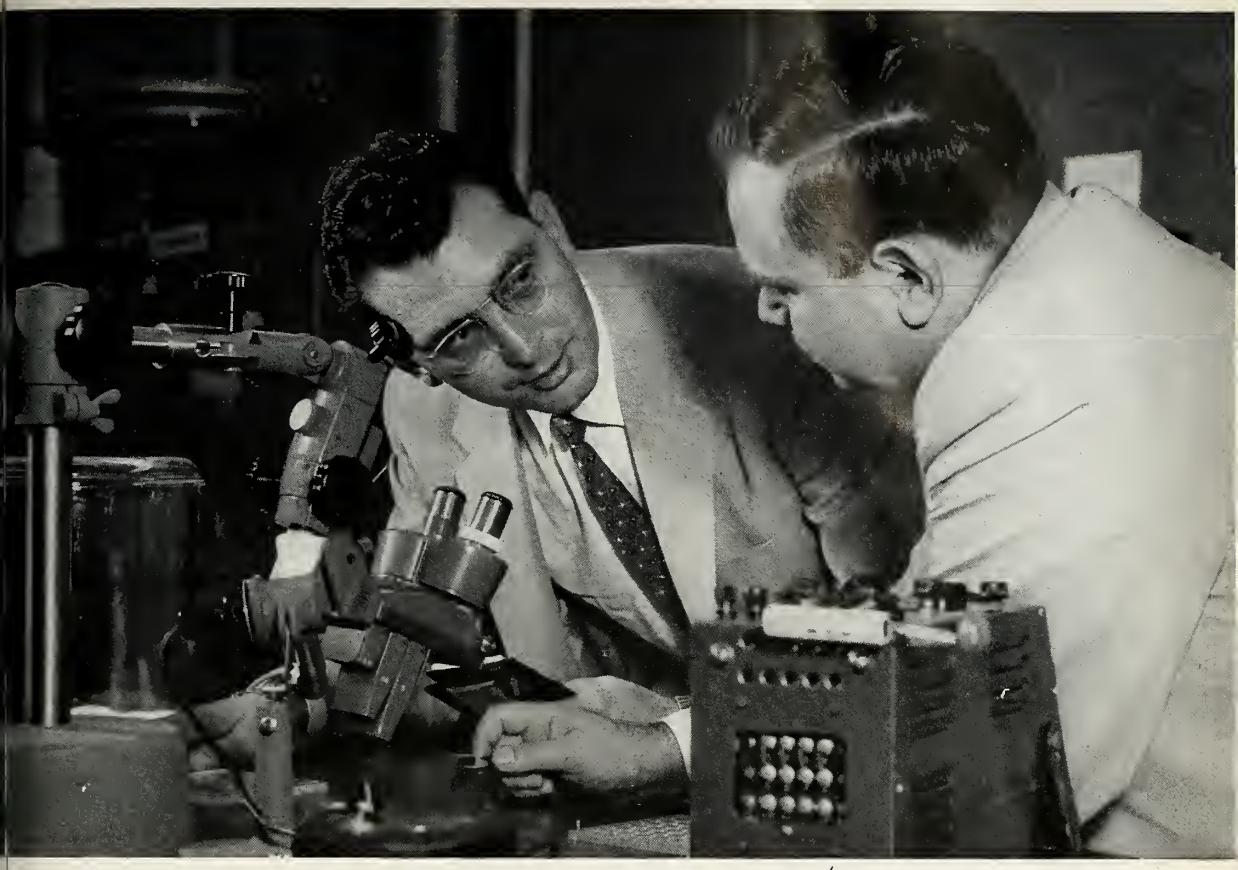
WHO READS MISSILES AND ROCKETS?

Well, for instance ... ENGINEERS AT WESTINGHOUSE DEFENSE PRODUCTS

Molecular electronics—a technological breakthrough at Westinghouse—is producing electronic systems *1,000 times smaller and lighter* than anything now in existence.

Through molecular electronics, drastic reduction in weight, size, power and heat dissipation requirements will permit space vehicles and satellites to perform a greater number and wider range of tasks. Greatest advantage is the vastly improved reliability achieved by the replacement of numerous components by a single solid state unit.



Recently, the Air Research and Development Command of the U. S. Air Force awarded a development contract to Westinghouse as a part of a broad program effort in this new electronic area. Experimental "hardware" is being fabricated by Westinghouse for infrared, reconnaissance, communications, telemetry, flight control and other military applications.

"Missiles and Rockets deals exclusively with astronautics. Spawned by aviation, missilery and outer space exploration today is an industry by itself." — George Shapiro (right), Fellow engineer of the Westinghouse Astronautics Institute, located at Air Arm Division.

"One company can't build the entire bird ... it takes thousands of p and scores of companies. Missiles and Rockets keeps us informed of products and capabilities of the other companies throughout the in try — a most definite aid in selecting contractors." — Harvey Sa (right), Manager, power systems, Westinghouse Advanced Syst Planning group.

Gene Strull (right), Manager of the Semiconductor Divi-
's Solid State Advanced Development Laboratory at the
tinghouse Air Arm Division, discusses molecular elec-
ics with Charlie LaFond of the editorial staff of Missiles
Rockets magazine. Westinghouse engineers have devel-
. on a single semiconductor wafer, a system that performs all the functions of much larger conventional and transistorized electronic systems. Typical application is a tiny light sensing device for satellite telemetry less than ½" in diameter and 1/100th of an inch thick, one of several subsystems including pulse generators and multiple switches, already built and demonstrated by Westinghouse.

is fast-growing, dynamic industry (missiles and
onautics) demands week-to-week technical and
s coverage. Month-old news and developments
of little use to today's engineer." — Jim Currie
), Radar Engineering Section Manager, Westing-
e Electronics Division.

WHY YOU SHOULD ADVERTISE IN MISSILES AND ROCKETS ... Missiles and Rockets has *no waste* circulation—just those who manufacture missiles, space vehicles and allied equipment—and active Government and military personnel. *Over 29,000 missile technicians pay for their subscriptions to Missiles and Rockets*—the *best* circulation story among magazines covering the missile market. Missiles and Rockets reaches the thousands of companies, NASA and the Department of Defense who are purchasers in this multi-billion dollar market.

Many Missile Programs Changed by Congress

by Betty Oswald

WASHINGTON—Major revisions of missile programs were recommended by Congress in approving defense appropriation of $39.2 billion for FY '59-60. Funds do not include an additional $1.3 billion for construction of missile bases and other military installations, a separate appropriations act.

While Congressional emphasis, centered on ballistic missiles and strategic weapons, there were signs of a growing concern over the capability of the U.S. and particularly the Army to handle a limited war. There were also indications Congress would take more of a hand in actual programming of military production if the Secretary of Defense did not take a firmer stand to eliminate interservice rivalries and what Congress considers duplicate development of equipment.

Some $1,407,300,000 was provided the Army for procurement of missiles and other equipment. Of this total, Army was ordered to take at least $100 million which had been made available for *Nike-Hercules* to make a start on Army modernization. Originally, the House provided the Army with $1,232,300,000 for procurement which the Senate boosted to $1.45 billion.

Navy will have $3,860,063,000 for procurement of missiles, aircraft, ships, and other hardware items. This includes $1,961,644,000 for missiles and aircraft; $1,330,700,000 for shipbuilding, including *Polaris* submarines and $35 million for planning for a second nuclear powered carrier; and, $567,-719,000 for procurement of ordnance and missiles (other than those used in aircraft).

Air Force will have $7,934,800,000 in new procurement money. Of this, $2,540,550,000 is for missiles, with the strong recommendation that the number of missile squadrons be increased and *Minuteman* be accelerated.

Actually, this could be increased if DOD decided to act. The Appropriation Act provided that the Secretary may take unobligated balances previously provided for aircraft and other procurement to boost ballistic missile programs. This is about $60 million under the budget.

Aircraft procurement money totals $4,284,000,000. This includes funds for armament, specialized handling equipment of the ground variety and other specialized equipment, including machine tools which may be needed. This account may also be boosted by use of previously appropriated but unobligated funds.

For research, development, test and evaluation a total of $3,165,615,000 was made available in new money to Army, Navy and Air Force. Of this, Army gets $1,035,715,000; Navy $970,000,000; and Air Force $1,159,-900,000.

Advanced Research Projects Agency gets an additional $455 million as requested by the President, and the Secretary of Defense's emergency fund of $150 million.

Defense Department has already changed some of the programs for which these funds will be used. Out of Army funds, $137 million will be used for preproduction preparation for *Nike-Zeus* missiles and equipment.

Nike-Hercules program has also been changed. A total of $10.8 million originally planned for research, development, test and evaluation won't be used under changed air defense plans. In addition, some $100 million of *Nike-Hercules* production funds will be used for Army modernization.

Air Force *Bomarc* program is also being reduced sharply under the so-called "master plan." The House originally took a little more than $162 million out of the *Bomarc* program. DOD asked a return of $129.9 million for *Bomarc* installations on the east and west coast. Senate provided about $80 million of the amounts which DOD asked to be returned. The Appropriations Act as it went to the President was a compromise giving the Air Force a little more than half of what the Pentagon had asked.

Congress made it clear that it didn't like either the *Bomarc* or *Nike* programs. Secretary McElroy is barred, by legislative history of the Appropriations Act of using any part of the emergency fund for *Nike-Ajax, Hercules* or *Bomarc*. And there is a strong suggestion, in addition, that the Secretary of the Army ought to start phasing out *Nike-Ajax*.

Plans to buy *Mace*, will have to be sharply revised. Originally $127.5 million was requested by DOD. The House knocked the entire fund out. However, the Senate gave the program a reprieve. It did not restore the money, as requested by the Pentagon, but provided that if the Secretary of Defense really wants the missile, he can take the money out of "maintenance and operation procurement and research and development funds in his discretion—."

Radar improvement programs of the Air Force were also cut slightly, hitting the SAGE project.

Simulator Delivery

Minneapolis-Honeywell Regulator Co. will deliver an 8 x 12-foot space flight simulator to the Air Force School of Aviation Medicine late next month. AF pilots are being screened for two volunteers to spend 30 days in the chamber. The eight-ton device includes air and water recycling devices. Solid wastes will be burned in an incinerator with gases disposed by afterburner. Environmental system will permit the volunteers to smoke cigarets and listen to recorded music.

Boeing has awarded RCA "Multi-million dollar" contract for command and information networks for *Minuteman* launch-control system . . . $1.9 million follow on for more *Minuteman* telemetry equipment has been ordered from **Radiation Inc.** by Boeing. Earlier contract was for $4 million . . . **Bell Aircraft** has picked up three AF R&D contracts totalling $575,000—one of them for development of a storable propellant flow system.

Corps of Engineers will soon ask bids for construction of *Nike-Hercules* bases at Barksdale AFB, La.; Dyess AFB, Tex.; Bergstrom AFB, Tex. Walker AFB, N.M.; Offutt AFB, Neb. Schilling AFB, Kan.; Robins AFB Ga.; Lincoln AFB, Neb. and Turner AFB, Ga.

DOD also has okayed construction of *Bomarc* bases at Camp Adaire, Ore. Paine AFB, Wash.; Vandenberg AFB and Travis AFB, Calif.

Aerojet-General Corp. is donating $400,000 to California Institute of Technology for construction of a new research laboratory. The lab will be named in honor of Dr. Theodore von Karman, who found Aerojet back in the late 1930's.

Boeing Proposes New Vehicle

Boeing Airplane Co. is advancing nd "interplanetary reconnaissance ve- icle" proposal that is a very blue-sky ntity with very real technical appeal.

According to the company's de- cription of the manned orbital- nterplanetary system, it would be apable of:

- Transport between planets by eactor-powered plasma jet;
- Reconnaissance of the orbited lanet by means of a "Boeing Martian xplorer" carried within and dis- atched from the main vehicle;
- Housing shuttle vehicles for per- onnel movement of vehicular service;
- Releasing personnel via self- ontained individual *Mercury* type scape and re-entry capsules.

The principal structure would be a 0x74-foot spherical-ended cylindrical shell. The interior would be divided into two ellipsoids independently pressurized and separated by a hanger deck.

Capable of being fully assembled in outer space, seven levels would be provided within the capsule. Nylon nets would compartmentize various levels.

The power plant would be separated from the habitated area by a truss structure and shadow shield. Communication to earth would be by paraboloidal reflectors and a solar-optical transmitter.

Study Shows Obsolescence

A **Johns Hopkins University** study for the Army labelling 75% of U.S. manufacturing facilities obsolete may increase chances for Congressional approval of changes in current tax depreciation rules.

Fast tax write-offs of equipment and facilities (amortization within 5 instead of 20-30 years) is due to end this year unless extended by Congress. The program was started during the Korean War and in the past few years has been reduced to mostly R&D for missiles and space systems.

Venus' Atmosphere Poses Entry Problem

Tests conducted in shock tubes by **Lockheed Missiles and Space Division** scientists indicate that for vehicles approaching Venus aerodynamic heating may be 50% higher than re-entry into the earth's thinner atmosphere.

AUSA Unveils New Army Missile Equipment

WASHINGTON—The Army last week elebrated the annual meeting of the ssociation of the U.S. Army by un- eiling a series of new Missile Age de- elopments ranging from a GI rocket elt to a "vest pocket" mobile air de- nse system.

The "vest pocket" system is con- dered capable of development as a eld anti-missile missile system.

Gen. Lyman Lemnitzer, Army chief f staff, set the tone of the meeting y warning that the Cold War is rapidly eaching the point of nuclear stalemate.

"The situation will then mean real- tically that the other components of ur power will play the vital role in pping with the tactics and strategy f Communism short of the threat of eneral nuclear war," he said.

He made clear that "the other com- onents of our power" meant very uch a missile-packing modern Army.

The Army disclosed that a soldier such an Army will be equipped with ich weapons as:

- Rocket belts of various sizes— ne belt under development by **Thiokol** ould give a GI up to 50 feet of boost om five solid rockets. Another bigger pe under development by **Aerojet- eneral** is capable of taking a man 200 feet into the air in 20 seconds.
- Rocket foxhole diggers—The ouble-tubed device is designed to dig foxhole by firing two rockets into the round.
- *Redeye*—The Convair anti-air- aft missile that can be handled by ne or two men in the field. It weighs ly about 20 pounds. (m/r Aug. 3)

The new **Hughes** "vest pocket" air defense systems are designed to semi-automatically direct the fire of from one to eight batteries of anti-aircraft missiles—*Hawks* and *Nikes*. They replace much manual operation.

The systems are comprised of from two to eight two-and-a-half ton trucks crammed with electronic equipment. The equipment—much of it modular—has been installed and designed to withstand travelling at high speeds over rough terrain.

One truck in each system serves as operations central. It detects and tracks attacking aircraft and routes the information to the appropriate coder-decoder truck. The coder-decoder truck in turn automatically routes the information to its battery.

The mobile systems already are being deployed with U.S. troops in Germany. In all, Hughes will manufacture 29 five-truck systems under a $30 million contract.

The cost of additional systems is estimated at about $500,000 each.

"VEST POCKET" DEFENSE against enemy jets is provided by the Army's new mobile tactical air defense system. The system—developed by Hughes Aircraft—is capable of semi-automatic direction of the firing of from one to eight Army anti-aircraft and missile batteries. Several of the five-truck systems are already in the hands of U.S. troops in Europe for use with Western-Electric *Nikes* and Raytheon *Hawks*.

HAMMER

Recent appointment of Brig. Gen. **Stephen R. Hanmer** as Deputy Chief of Engineers for Military Operations has been announced. Gen. Hanmer, who has been Assistant Chief of Engineers for Troop Operations, will have supervision over the Corps' military activities, including training and assignment of Engineer personnel, and research and development of missile ground support equipment and techniques.

CAIRELLI

C. P. Cairelli, new chief engineer of M. H. Rhodes, Inc., Hartford, Connecticut, has been with the company for three years as design engineer. He will direct Rhodes' expanded engineering program.

Irving H. Young has been named manager of engineering administration at Litton Industries' Maryland Division. He formerly was an engineer with General Electric's aircraft nuclear propulsion department in Cincinnati. **Fred E. Burnham** assumes position of manager, antenna and microwave section at Litton after ten years with Wright Air Development Command. He was assistant chief of the antenna techniques and applied research section.

William James Weaver takes over as product specialist at F. J. Stokes Corp., Philadelphia. He was formerly with Air Products, Inc.

SOLARI

Sterling Precision Corp. has announced election of **Joseph Solari,** vice president, as a director of the corporation. Solari has also been elected to the board of American LaFrance, Yawman and Erbe, Prescott, Alf-Herman, Weck and Wood and Brooks. He will continue responsibility on the operation of the Instrument Division at Port Washington, New York; the Inertial Navigation Division at Cambridge, and the Weck Division in Brooklyn.

France's Nord-Aviation has named **Leon Beaussart** as vice president (technical) of their Missiles Department. **Roger Chevallier** is promoted to chief engineer of the target missiles section; **Jean Guillon** chief engineer of the autorotating missiles and **Roger Fleury,** chief engineer, for missile development and support equipment.

ROSS

Harvey M. Ross, chief engineer of Motorola's Defense Systems Laboratory has been named manager of Program Development, a new position "reflecting the continued expansion of Motorola's military activities in Phoenix." He joined Motorola's Communications and Electronics Division in 1948 and was promoted to department head in the Military Electronics Division.

Paul R. Ellis, former manager of ACF Industries, South Albuquerque Works, has been promoted to manager of the division.

DUNCAN

Dr. Donal B. Duncan, 34, has moved to Aeronutronic, a Division of Ford Motor Co. as assistant general operations manager of Space Technology Operations. He was manager of Advanced Engineering at Autonetics, a Division of North American Aviation Inc.

Barnett Pomerantz takes over as project engineer at Bulova Research and Development Laboratories, Inc., for aircraft altimeter development and production programs. Pomerantz came to Bulova a year ago, from Swivelier, Inc. where he was chief engineer.

SILK

C. Earnest Silk heads development of solid propellants and explosives operations of the Energy Division, Olin Mathieson Chemical Corp. and will be responsible for development operations at East Alton, Ill., and Ordill, Ill. Silk, who joined the then Olin Industries in 1930, and has worked in research, manufacturing and engineering phases of the business, holds patents for explosive processes.

west coast industry . . .

By Fred S. Hunter

Ryan Aeronautical Co. keeps pushing . . .

toward higher altitudes with its *Firebee* jet target missile. When Ryan first started drawing lines on paper for the XQ-2 in 1947, it was to meet a requirement for 15,000 feet of an anti-aircraft target. Its newest model, the Q-2C, has achieved a record of 59,500 feet and, in addition, has set a duration record of 77½ minutes above 50,000 feet. Next step will be a supersonic *Firebee*. Ryan, says Frank Fink, vice president-engineering, is thinking in terms of Mach 1.5 and then going on from there.

First objectives in Ryan's program . . .

to provide supersonic capabilities in the *Firebee* may be met with a two-stage version of Continental's J69-T-29 engine which powers the Q-2C. This would increase the Dash 29's 1700-pound thrust rating by approximately 50%. Ryan's own engineers are working on the development of an augmentation system for this same engine. This would be in the form of a simplified afterburner which could be cut in after the drone is on station. Cost of a current *Firebee*, including augmentation and scoring equipment, comes to $50,000 or $60,000. A supersonic *Firebee* probably would cost twice as much. But higher and higher performance target systems have to be developed to meet the requirements of advances in weapons systems. And Ryan's people make a cogent point—often the cost of the munitions (rockets) used up in a target mission exceeds the cost of the recoverable *Firebee*.

Steel strike may affect missile industry . . .

on the labor front as well as in the supply of material. Roy M. Brown, International Association of Machinists general vice president for the southwest area, made this observation at the recent western states conference of the IAM in San Diego: "What happens in steel will affect negotiations in other industries, including contract talks coming up in the aircraft and missile fields next spring."

NASA will come into the X-15 flight . . .

program at an early date. Immediately upon conclusion of proving flights, **North American Aviation** will turn the No. 1 aircraft over to NASA for test by its pilots. With two B-52s available for mother ships, North American will continue with its program on the No. 2 aircraft. A major change in flight technique will take place with the entrance of the No. 3 aircraft into the program. Interim engines in the No. 1 and No. 2 aircraft will be lighted after the rocket plane is dropped from the mother B-52. The big 60,000-pound thrust rocket specially developed for the X-15 will be lighted just before the aircraft is released.

How big is the missiles and rockets business . . .

getting to be? Well, **Aerojet-General** says at Sacramento it has the largest telephone switchboard west of the Mississippi and is expanding it. The company's telephone bill is $85,000 a month. And if the stock market is your barometer, consider, then, in the last 18 months, prices of shares of **Ampex** and **Hoffman Electronics** have increased more than fourfold, **Hewlett-Packard** and **Stratham Instruments** more than threefold . . . J. E. Rheim, **Rohr Aircraft** president, says the next two or three years should be "the best we've ever had." Rohr has $150 million of business lined up already for fiscal 1961.

Transfer of satellite launchings from . . .

Vandenberg Air Force Base to the Navy's Point Arguello will probably become effective after January 1, 1960. The switch is purely in the interest of geographical efficiency. There's nothing between Arguello and the South Pole except ocean.

ADVANCED PRELIMINARY DESIGN ENGINEERS

The creation of the new Preliminary Design Department of our Solid Rocket Plant has led to several unusual and challenging positions for experienced engineers and scientists.

We are expanding:

into new fields of rock propulsion and space technology, far beyond "classical" solid propellant rocketry. For this we are an internationally acknowledged leader.

We are looking for:

mature, experienced and highly versatile engineers, preferably over 30 years old. These men will be mechanical, aeronautical, or missile engineers. They may also be engineering-minded physicists or chemists. An M.S. degree is essential, a Ph.D. welcome. A high degree of proficiency in such fields as thermodynamics, aerodynamics, heat transfer, stresses, and physics is required, as well as a practical understanding of manufacturing fundamentals. Each of the men we are seeking must be capable of integrating the essentials of a new design, based on the more quantitative work of our several analytical groups.

Eight positions as "Technical Specialist" in our Preliminary Design Department are available. Each successful candidate will work on this team as an equal among equals. These top engineers will be given enough responsibility and freedom to work as they see fit. Excellent salaries are offered, commensurate with demonstrated ability and experience. The Sacramento, California, area offers a favorable, healthy climate and living conditions which are among the finest in the country, one and a half hours driving time from either the Sierra Nevada Mountains or San Francisco.

Please send your resume and direct any detailed questions to:

Mr. Emil L. Eckstein
Head, Department for Preliminary Design
Through:

Mr. E. P. James, Supervisor

AIR FORCE

Radio Corp. of America has received a "multi-million dollar" major research and development contract for work on the sensitive-command and support information networks of the *Minuteman* launch-control system. (Subcontract from **Boeing Airplane Co.**)

$83,966,000—**Pan American World Airways, Inc., N.Y.**, for increased funds for services and material for management, operation and maintenance of the Atlantic missile range facilities and related activities of the AFMTC. (Two contracts.)

$1,900,000—**Radiation Inc.**, Florida Div., for the ground portion of the PCM/FM telemetry equipment for the *Minuteman* ICBM. (Subcontract from **Boeing Airplane Co.** and is in addition to an earlier $4,000,000 contract.)

$1,000,000—**The Garrett Corp., AiResearch Div.**, Phoenix, for vent and relief valves and high pressure regulators for the *Titan* ICBM. (Subcontract from **The Martin Co.**)

$575,000—**Bell Aircraft Corp.**, Buffalo, N.Y., for development of a storable propellant flow system for rocket engines; feasibility study for the electrostatic suspension of accelerometers, and a method of determining the effect of structural flexibility on the stability and control of hypersonic air vehicles. (Three contracts.)

$450,000—**Consolidated Diesel Electric Corp., Aircraft Equipment Division**, Stamford, Conn., for transformer-rectifier type power supplies.

$36,000—**Traid Corp.**, Encino, Calif., for 16mm hi-speed camera.

$30,530—**Boeing Airplane Co.**, Pilotless Aircraft Div., Seattle, for technical data for IM99A missile components.

$20,000—**Southwestern Industrial Electronics Co., Div. of Dresser Industries, Inc.**, for electronic instrumentation Model K-1 microsource.

NAVY

Contracts totalling $12,000,000 have been awarded **Sperry Gyroscope Co.**, Great Neck, N.Y., for the development of the Mark 112 Torpedo Fire Control System, an electronic "brain" that controls torpedos even after they are fired. The first will be installed on the *Polaris*-launching submarine, the USS George Washington.

$1,920,000—**Ryan Aeronautical Co., Electronics Div.**, for additional spare parts and other support equipment for the Model APN-122(V) Doppler Radar Navigator.

$425,000—**Elgin Micronics, Div. of Elgin National Watch Co.**, Elgin, Ill., for the production of safety-arming devices used in the *Sparrow* missile.

$330,000—**Brubaker Electronics, Inc.**, Culver City, Calif., **Div. of Telecomputing Corp.** of Los Angeles, for the manufacture of complex radar test equipment and spare parts.

$225,000—**Vitro Laboratories**, Silver Spring, Md., **Div. of Vitro Corp. of America**, for the expansion of services in the field of weapon system simulation and training devices. (Four contracts.)

$134,000—**Packard Bell Computer Corp.**, Los Angeles, for data gathering system.

$71,876—**Bendix Computer Div.**, Los Angeles, for digital computing system.

$61,840—**Avion Div., ACF Industries, Inc.**, Paramus, N.J., for radar beacon assembly.

ARMY

$9,950,000—**Western Electric Co., Inc.**, N.Y., for *Nike-Zeus* industrial planning program.

$3,023,204—**Chris Berg. Inc.**, Seattie, Wash., for construction of tracking and data acquisition station at Donnelley Flats, near Fort Greeley, Alaska.

$2,500,000—**North American Aviation**, Canoga Park, Calif., for design and development.

$2,358,670—**HRB-Singer, Inc.** and the **Singer Manufacturing Co.**, a joint venture, State College, Pa., for infrared surveillance system.

$1,934,519—**Hazeltine Electronics, Div. of Hazeltine Corp.**, Little Neck, N.Y., for radar set An/TPS-25.

$803,452—**Ford Instrument Co., Div. of Sperry Rand Corp.**, L.I., N.Y., for airborne guidance receiver transponder.

$800,000—**ITT Laboratories, Div. of International Telephone & Telegraph Corp.**, Nutley, N.J., for three ground stations for *Courier* communication-satellite systems.

$700,000—**Philco Corp.**, Philadelphia, Pa., for *Courier* communication satellites, shrouds, code tapes.

$440,000—**The Trustees of Columbia University**, N.Y., for research and experimental work in the continued investigation of electromagnetic spectrum, together with technical reports. (Two contracts.)

$420,315—**Firestone Tire & Rubber Co.**, Los Angeles, for engineering services.

$350,000—**Union Carbide Development Co., Div. of Union Carbide Corp.**, N.Y., for research in physical and chemical principles affecting high temperature materials for rocket nozzles.

$349,403—**Gilfillan Brothers Inc.**, Los Angeles, for engineering services.

$340,948—**Ford Instrument Co.**, L.I., N.Y., for eight sets of modified *Redstone* guidance and control components.

$226,021—**Collins Radio Co.**, Dallas, Texas for microwave relay for wide band telemetry, White Sands Missile range, spare parts list.

$179,364—**Radio Corp. of America, Defense Electronic Products**, Moorestown, N.J., for investigation into requirements of special test equipment for cross section measurements, design, fabricate and installation of necessary special test equipment determined to be applicable.

$139,000—**Bulova Research & Development Labs., Inc.**, Woodside, N.Y., for study, design and fabrication of nine prototype accelerometer monitors and mico-miniaturized three-speed synchro assemblies utilizing size eight synchros for the ground equipment to be used in the *Jupiter* guidance system and for study and development of basic research tool applicable to gun launchable guidance systems. (Two contracts.)

$81,950—**Defense Electronic Products**, Camden, N.J., for investigation studies pertaining to advance development of microwave radio relay systems together with technical reports.

$65,060—**Atlantic Research Corp., Alexandria**, Va., for one design and test plan for radiosonde AN/DMQ-6 and subsequent delivery of 15 development and 50 engineering test models.

$53,720—**Wild Heerbrugg Instruments Inc.**, Port Washington, N.Y., for modification of government-owned ballistic cameras.

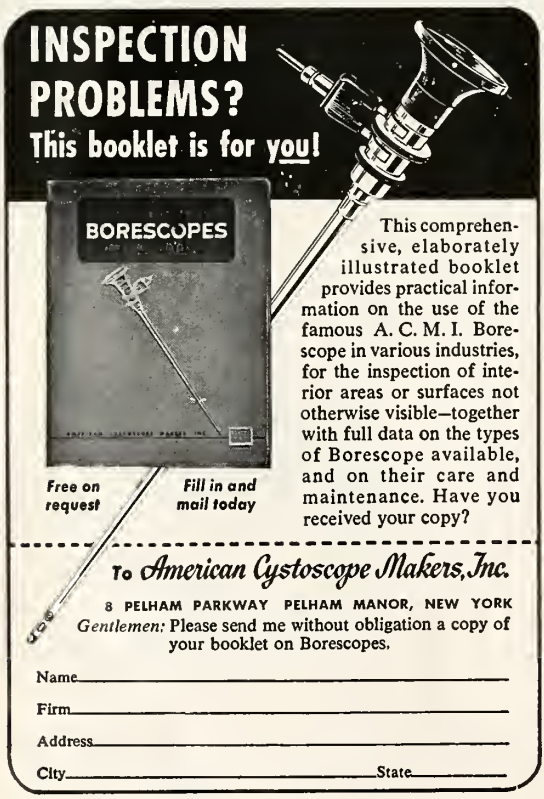
$51,539—**University of Wisconsin** for research work for 24 months to conduct surface wave antenna and microwave filter engineering study and technical reports.

$42,736—**University of Pittsburgh**, for basic research related to low energy nuclear and electron physics and research and development entitled "The Reactivity and Molecular Constitution of Some Metal Hydridies in Solution."

$40,182—**Western Electric Co.**, N.Y., for *Nike* spare parts and components.

$38,000—**Litton Industries**, San Carlos, Calif., for magnetron tubes.

MISCELLANEOUS



$794,000—**Applied Science Corp.** of Princeton, N.J., for digital data transmission systems for the Eglin Gulf Test Range. (Subcontract from **ITT Laboratories**, a division of **International Telephone & Telegraph Corp.**)

$350,000—**Consolidated Avionics Corp.**, subsidiary of **Consolidated Diesel Electric Corp.**, Westbury, N.Y., for automatic test equipment for testing electronic missile components and circuits. (Subcontract from **General Electric Co.**)

$75,000—**Consolidated Avionics Corp.**, Westbury, N.Y., for data reduction system. (Subcontract from **Boeing Airplane Co.**)

BIDS

U.S. Army Engineer District, Pittsburgh, Corps of Engineers, New Federal Bldg., Pittsburgh, Pa.: Construction of ground-air transmitter and receiver facility for the *Missile Master*, Pittsburgh Defense Area, Collier Township, Allegheny County, Pa. Bid sets available after 24 July 1959. Completion 165 calendar days—Job—IFB Eng-36-058-60-1B—Bid opening on or about 25 Aug. '59.

Reliability Interest

To the Editor:

I have read with interest the articles written by Managing Editor D. E. Perry and Col. J. N. Dick, USAF, Ret., in the July 13 issue of MISSILES & ROCKETS and was prompted to reply with some thoughts of my own. The fact notwithstanding that new materials and components will be required for future equipments, I question how much we know about the reliability attributes of those presently available.

It is my belief that our knowledge is inadequate and our needs are immediate. Further, that we are actually attempting to design reliable equipments without sufficient reliability information concerning the parts from which they are to be constructed. With sufficient component reliability data available to the design engineer at the time that he is building his dream, there should be marked decrease in the number of nightmares that occur in test and production.

To stress my point, let us suppose that the designer had a reliability requirement in addition to accuracy, altitude, size, etc. A rather unsophisticated technique for a rough computation could be explained to him. Suppose further that some of these computations require the data that associates failure rate, temperature and electrical stress (voltage, wattage, etc.) for the various components that he is to use. Where does he obtain this information concerning either new or relatively new components. It appears that he doesn't unless either his company has been funded for a large components evaluation program or has access to data from another company or a government agency.

To gather these types of data through testing program is a costly process for any company, but it could be done on a national scale at Government expense. Dissemination of these design data could be either upon request or included with the documents associated with an equipment specification.

Considering military component specifications for a moment and the fact that they contain certain requirements for size, rating, etc., should they not contain reliability requirements as well? It would seem that we are not exploiting to best advantage those components that are in and today because of the lack of sufficient information concerning their reliability attributes.

This does not mean that we cannot expect to require new component types to meet the demands of future equipments. However, suppose that the suggestions made by Col. Dick are accepted and new materials are developed. Will we know any more about their failure rates in equipment application than we now about those that we are using today? Certainly not, if the developmental investigations are conducted without forethought for the reliability data required to make use of them.

In summary, and as Col. Dick's article suggests, let's really put "first things first" and find out what our components will do in a reliability sense. If we are able to accomplish this, we should be able to design reliability into equipment just as any other design requirement. Reliability is no longer an art but a science; therefore, there is a need for scientific information in its aplication.

E. G. Lebre, Manager
Reliability & Specification
Compliance Department

Navy Fails to Solve ASW Problem

It is basic military doctrine that close behind any new offense will appear a defense. The time and the effectiveness vary but historically the doctrine has proven itself, the world has watched this spectacle of defense and offense leap-frogging each other over the war-marked centuries.

It is in the periods when the development of the defense lags unduly that nations find themselves in the greatest danger, whether the weapon be the phlanx, the catapult, the long bow or the satellite missile-firing platform.

The United States today finds itself facing such a problem in not one but two fields. The first is the anti-ballistic missile missile. The second is in anti-submarine warfare. Of the two the second seems to us to be much the more dangerous for two reasons.

First: despite a great deal of talk about the "missile gap," the probability is that both the United States and the Soviet Union will actually perfect long range ballistic missiles in roughly the same time period. Any advantage the Russians may have for a short time will be offset by the Western Allies long range bomber force. These factors seem likely to prolong the same sort of stand-off under which the world has been living, perhaps indefinitely.

Second: No such equality of force exists between the Soviet and U.S. submarine fleets. It is true that we have the first atomic submarines and are building more, and that their feats have been spectacular. But indications are the Russians will not be far behind with their own atom-powered subs. Certainly their accomplishments in the reactor field in other endeavors can leave little doubt that they have such a capability.

The more important fact is that the Russians have a huge fleet of some 500 submarines as opposed to 113 in operation by the United States (five nuclear).

Times and tactics have changed a great deal since World War II. Then the submarine was intended and directed to operate exclusively against other ocean craft. Today the submarine has the capabality of operating not only against shipping but against the cities and military installations of the enemy as well.

In the first instance, in the words of Rear Admiral John S. Thach, commander of the Navy's Task Force Group ALFA;

"Hitler started his war with about 60 U-boats, the old fashioned kind that could submerge only temporarily, and he nearly strangled us. The Russians have eight times that many right now. Most of them are new. They're fast. Snorkels are standard equipment. Nuclear propulsion is only a matter of time." Admiral Thach is one of the Navy's sailors responsible for building a submarine defense. He will admit that in war games his own opposing snorkel subs confound his defenses all too frequently.

Even if we ignore the possibility that the Red subs might throttle the sea lanes, concentrating on the theory that the next war will be short, if unhappy, and that supplies can be handled via the air, this does nothing to dispose of the missile-throwing sub which could operate in the Atlantic, the Pacific and the Gulf.

Since we have not and probably will not have for some time a defense against a ballistic missile—certainly not against one fired from short range—then the problem here is exactly the same as the problem of protecting shipping. The only defense is to get the submarine itself. And a conventional sub can toss a missile just about as well as a nuclear sub.

Industry, which has been working fitfully on this problem for some years, details two main obstacles they have run into—and many responsible Navy officers agree. These are:

Lack of money—The price of one carrier, for instance, would go far toward the solution.

Concentration of effort—Instead of scattering the responsibility between The Bureaus of Ordnance, Ships, Aeronautics and the Office of Naval Research.

A poll of more than a score of companies who have worked on the ASW problem, including putting their own funds into it, has revealed almost an unanimity of response on the latter fact. Almost invariably it went like this:

"One of our greatest problems in dealing with the Navy on ASW is that there is no single group within the Navy Department responsible for the entire anti-submarine field and, therefore, it is difficult for a contractor to anticipate or, indeed, discover the total needs of the service in this area."

And another, from a company which had spent $100,000 of its own funds:

"The most difficult problem encountered to date in conjunction with ASW is the lack of consistency among many Navy agencies as to what the requirements of the Navy really are in the ASW area."

It seems to us that the conclusion is inevitable. There are many precedents in the Services for establishing a special group—task force, division, command, call it what you will—to concentrate the best skills of the Navy and industry toward solving one of the most dangerous threats which the country faces. It should be done quickly. And it should be given a priority on money and manpower to be successful.

ITIVE FUSE. A current-sensitive having a functional reliability of % is announced by Networks Elec- Corp. Glass-enclosed and hermet- sealed, the fuse is 100% humidity , and guaranteed to meet any ied resistance to atmospheric con- s. Unit has excellent environmental cteristics, withstanding tempera- from −100°F to +400°F . . . ion of 10 to 500 cps at 15 G's ium, and shock of 50 G's for 11 conds. Fuse is dimensioned to dis- heat produced by the maximum current under any special blowing and temperature conditions. Fast, m or slow burning-operating time vided. The slow-burning fuses have h time-lag, with standing heavy ; and instantaneous peaks, but g quickly in response to short cir- Units are filled with nitrogen or specified gases. Outside ends of rminals are flexible copper alloys straight cutoffs, or flattened-and- d lugs. Fuses can be designed and ged to customer specifications.

No. 245 on Subscriber Service Card.

OTEST CONSOLE. Solartron, Inc. a new console providing a con- t housing for selected items of est equipment, plus working sur- for use as a plotting desk or as d for units under test. The con- was designed to house Solartron nents such as its low frequency e oscillator, low frequency resolved onents indicator, Solarscope, con- s, sub-sonic power amplifier and nical reference generator. How- the manufacturer also suggests cer- ther instruments as being applic- n the servotest field.

No. 246 on Subscriber Service Card.

SDUCER. Astra Technical Instru- Corp., is now marketing a tung- resistance thermometer having a tless connector of 2 ounces. These possess the high accuracy and wide rature ranges characteristic °F to +2000°F) of the com- standard laboratory probes. lucers feature body rotation inde- nt of leads for ease of installation, re extremely rugged to withstand ibration and shock.

No. 248 on Subscriber Service Card.

PLANETARY MIXER-DISPERSER. A heavy-duty vertical planetary mixer, only 14 feet tall and powered with a four-speed, 20 horsepower, explosion-proof motor, has been produced by the Bramley Machinery Corps. Mixing is performed in the 250 gallon, stainless steel, mixing chamber by means of specially designed, wedge-proof paddles, one stationary paddle and one rotating paddle moving on its own axis in a planetary orbit. The paddles intermesh, thereby performing a continuous and quicker kneading and squeezing action between the paddles. The mixing chamber is jacketed around the periphery, including the bottom, for either cooling or heating, with an allowable internal working pressure of 50 PSI. A separate hydraulic system raises the mixing chamber and holds it to the head, to permit the mixing operation to be conducted under high vacuum.

Circle No. 249 on Subscriber Service Card.

DIFFERENTIAL. The Dynamic Gear Co. has introduced a miniature, precision three-gear differential for application in the fields of electronic computers and fire control systems. Designed, manufactured and available from stock, this differential has a backlash of only 8′ of arc and breakaway torque of .3 oz. in. Tumbling circle is 1.380″. Maximum recommended load at 2500 RPM is 75 oz. in. Featuring 6 precision bearings, this solid shaft differential is entirely constructed of 303 stainless steel—except the spider gear, which is 24 St aluminum. Overall length of the differential proper is 1.888 and shaft diameter is .1847. Shaft lengths are available up to 4″.

Circle No. 250 on Subscriber Service Card.

PROPELLANT TESTER. A "drop-weight tester" developed by the Olin Mathieson Chemical Corp. for impact testing liquid propellants and explosives is offered by Technoproducts Inc., exclusive licensee. The test method, developed by Olin Mathieson in a five year cooperative government and industry program aimed at standardization of propellant testing, has been accepted as a Recommended Test by the Joint Army-Navy-Air Force Panel on Liquid Propellant Test Methods.

SURFACE COATINGS. A chart providing thermal, physical, chemical and electrical characteristics of HumiSeal protective surface coatings for electronics applications is now available from the Columbia Technical Corp. Prepared so that all characteristics can be seen at a glance on one side of the sheet, the chart covers the ten HumiSeal types broken down by the A.I.E.E. thermal classification as well as 47 other specific characteristics for each type. The reverse side has a selector table which enables the user to select the HumiSeal type best suited for the property most desired for his application.

A. C. TIMING MOTORS. The A. W. Haydon Company has released a Bulletin—AWH MO-807—describing a line of compact, reversible AC Timing Motors. These motors are supplied with built-in gear trains offering speeds from 450 RPM down to 1/4 RPM. Identified as the 26100 Series, these motors were designed specifically for applications where ease of reversing is the main requirement, and where small size and light weight is necessary. The synchronous characteristic of these hysteresis type motor assures an accuracy on the same order as the power source. Operation can be on single phase supplies, using a phase shift network supplied with one winding, or on two phase supplies. Reversing is accomplished rapidly and conveniently with a single-pole double throw switch.

Circle No. 201 on Subscriber Service Cord.

SENSITIVE DETECTOR. Technical bulletin no 91411 describes the theory and operation of a visual phase sensitive detector manufactured by Boonshaft and Fuchs Inc. This test instrument is used in the performance evaluation of a-c servo amplifiers and mechanisms. Other applications are also listed. Block diagrams, waveforms, and test setups are shown in the bulletin, as well as a chart illustrating the demodulation of various carrier signals of different phase relationships.

Circle No. 202 on Subscriber Service Cord.

TRANSFORMER. A "do-it-yourself" transformer, called the Flexiformer packaged transformer primary, which makes stocking of many fixed-ratio transformers unnecessary, is described in a bulletin released by the Superior Electric Co. Essentially, a Flexiformer is a self-contained toroidal primary coil consisting of a strip-wound silicon steel core having a coil of 400 turns of #24 B&S guage copper wire. When used as a source of a-c voltage, simply hand-thread the proper number of secondary winding turns through the center opening to obtain the desired output voltage. Input rating is 120 volts, 50/60 cycles, 1-phase and output is 150 VA. When used as a current transformer, the Flexiformer winding becomes the secondary winding with the current induced by a wire passing through the center opening. Used with a 0-1 ampere ammeter, currents up to 400 amperes can be measured with an accuracy of 1% at 60 cycles.

Circle No. 203 on Subscriber Service Cord.

GAS REGULATORS. A new line dustrial gas regulators without g is described in a data sheet now able from Linde Company, Divisi Union Carbide Corp. The new gau regulators eliminate the costly an noying problem of gauge breakag replacement. Designed for use wit gen, acetylene or propane on cyl or manifolds the new Oxweld regu are designated the R-550 (Oxyge 551 (Acetylene) and the R-552 pane). Complete specifications an erating data on the new large-ca single-stage regulators are includ the data sheet. The new regulato extremely valuable on jobs where lators are subject to rough handli switched from cylinder to cylinde quently. Use of an absolute mi number of parts in the gaugeless lators reduces the number of part ject to wear. It is rarely necessa replace parts other than the stem of diaphragm.

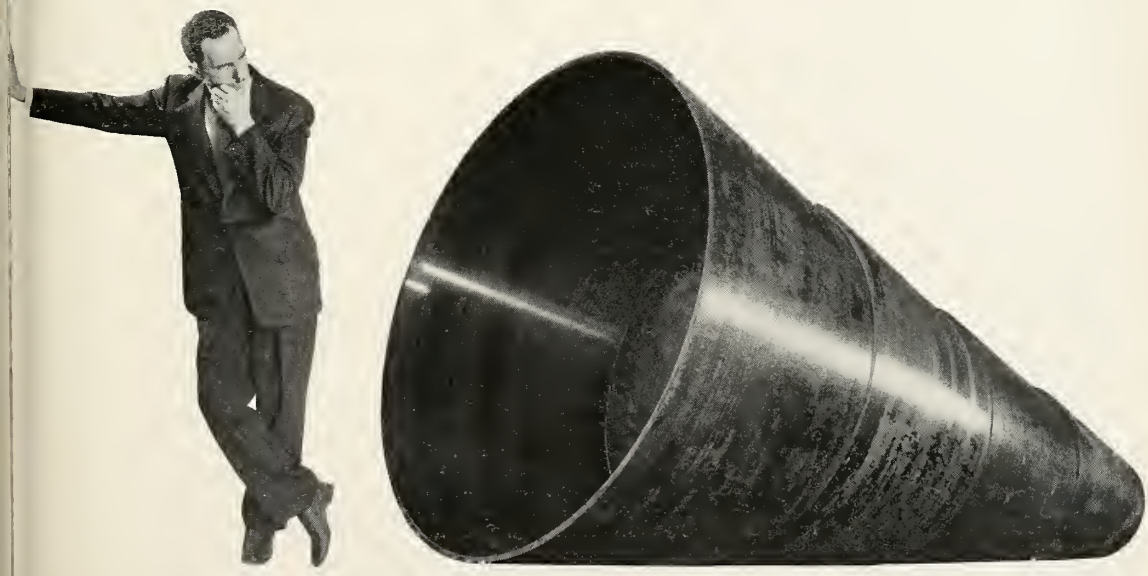
B.F.Goodrich



WHAT IS IT? Probably the biggest homogeneous void-free laminate ever built . . . a B. F. Goodrich ablation shield for an experimental re-entry vehicle designed and built by General Electric to be test flown on an Air Force Atlas ICBM.

Fabricated by a special B. F. Goodrich winding technique, the shield contains about five miles of high-temperature resin tape. This fabricating technique, which is also being used for many other specialized B. F. Goodrich products of various types and sizes, completely eliminates precision matched metal molds, cuts tooling costs by hundreds of thousands of dollars, and saves plenty of lead time. Autoclave curing replaces massive high pressure presses.

Throughout the construction of this re-entry vehicle shield, B. F. Goodrich maintains constant quality control of resin content and residual volatiles. Modern radiological facilities are used for final checking.

The fabrication and curing of such huge void-free parts illustrates the advances made by B. F. Goodrich in producing high-temperature, reinforced plastic products. So if you're up in the air and want down-to-earth answers on plastic laminate constructions, contact *B. F. Goodrich Aviation Products, a division of The B. F. Goodrich Company, Dept. MR-89, Akron, Ohio.*

Electro Instruments Model A12 D.C. Amplifier

Totally transistorized—dissipates only 7 watts.
Long term drift less than 2 microvolts.
.01% linearity and stability.
100 megohms input impedance—40 milliohms output impedance
1 db DC to 10 KC.
Noise less than 10 microvolts wideband.
Single ended or differential input.
Operates to specifications from 0° to 50° C.
Self-contained power supply—operates on any line frequency from 50-400 cps.
Mil-type chopper gives unmatched reliability for the life of the instrument.
7" x 19" panel accommodates 8 instruments.

Plug-in attenuators of the A12 provide convenience, flexibility and economy. Special variations, gain settings, etc., can be tailored to your system at no extra cost.

LEACH SUBMINIATURE CRYSTAL CAN RELAYS

(SHOWN ABOVE...ACTUAL SIZ

torture-tested to perfection for big relay performance

These sensitive Leach subminiature relays deliver big relay performance . . . in a crystal can size that makes them ideal for use in missile control circuits in airborne or ground equipment and in computer and printed circuits.

Torture-tested to perfection in the Leach Production Reliability Center, these subminiatures are designed to meet the critical extremes of vibration, shock and other stringent environmental requirements in military and commercial applications.

They meet the specifications of both MIL-R-25018 and MIL-R-5757C—as well as MIL-R-6106C, *including the minimum current test requirements.*

Uniform contact pressure and overtravel are guaranteed for the life of these balanced-armature relays. They are available in a wide range of socket, stud and bracket mountings to meet specific customer requirements.

Write today for Leach Crystal Can Relay Brochure containing specifications, typical ratings and other information on these subminiatures! Or contact your nearest Leach sales representative to discuss your specific subminiature relay requirements.

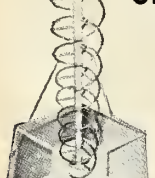
SPACE COMMUNICATION ANTENNAS

ANDREW



Quad-Helix antenna

tracks long and medium-range missiles

Telemetry circuits between missile (or satellite) and ground station are reliably maintained with the ANDREW Quad-Helix Array. This system offers low VSWR, high gain, and easy control.

Gain is 17.5 db at 265 mc, 14.5 db at 215 mc. VSWR is less than 2.0:1 across this range. Polarization is right hand circular; impedance 50 ohms. Counterbalanced rotator provides 180° elevation and 720° azimuth tracking at speeds from 0° to 30° per second.

Optional remote control unit regulates speed and direction.

Another of the many ways ITT electronics saves time and money and speeds output

Flick the dial of an ITT intercommunication telephone.

Instantly, it becomes a "conference room"—linking 10 key people simultaneously.

They talk together, exchange ideas, reach decisions — *without leaving their desks!*

ITT electronics—a help for business

This ten-party conference telephone is one of hundreds of ideas developed by ITT's Kellogg Switchboard and Supply Company and other ITT units to help perform tasks—faster.

ITT supplies telephone systems for entire countries. It develops communications and guidance for missiles; radio aids for aircraft and ships; microwave systems that control the flow of oil, gas, and electric power.

Nations are joined by ITT coaxial cable systems; news of the world is broadcast by ITT transmitters and power tubes—in fact, ITT equipment is produced for every communications need of business, industry, and government.

Skills for international projects

ITT has decades of experience in operating nationwide telephone networks. ITT System commercial circuits—cables, radiotelephone, radiotelegraph, and marine radio—cover the earth.

An ITT System company operates and maintains the 3,000-mile DEW Line in the Arctic, the White Alice communication network in Alaska, and other vital lifelines of defense. ITT has the senior part in planning the modernization and extension of the Air Force's global communications conce called AIRCOM.

In countless other ways ITT Syst research, production, and service speeding the world's growing commu cations traffic.

For information on any communi tions system write to ITT, 67 Bro Street, New York 4, N.Y.

OUTPERFORMING all operational target missiles, Ryan's *transonic* Firebee has just set new world's records for altitude and duration-at-altitude.

...it flies *higher*—59,000 feet

...it flies *longer*—96.8 minutes *(77½ minutes above 50,000 feet!)*

...it flies *faster*—Mach .95

Now being produced for the Air Force (Q-2C version), Ryan's new *transonic* Firebee contains advanced, built-in auxiliary devices to better simulate enemy aircraft. It has the performance needed to challenge America's most advanced weapon systems under realistic combat conditions.

The *transonic* Firebee is the result of Ryan's unmatched ten years of design and operational experience in the jet target field.

In 1949, Ryan built the first jet target missile ... today more Firebees are in service—with the Air Force, Navy, Army, and Royal Canadian Air Force—than all other jet targets *combined*... and now, with this new *transonic* Firebee, Ryan gives proof again of its continued leadership in the design and development of jet targets.

COUNT DOWN

for the conquest of space

"MISSION ACCOMPLISHED: DEPARTING LUNA 2205 ZEBRA"

This message, flashed across a quarter-million miles to Washington, D.C., will be awaited anxiously by millions.

But even then our first expedition to the moon will still face its most crucial test—the journey home to earth.

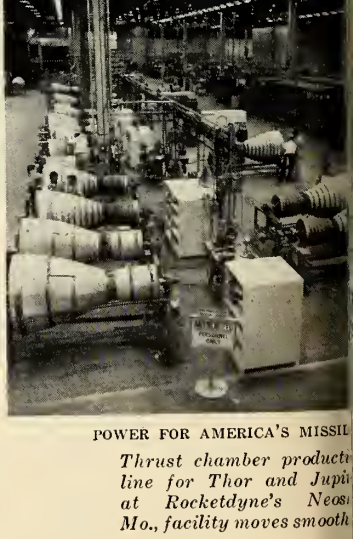
The success of that trip will depend in large part on rocket propellants—fuels and oxidizers that will have been stored for days in the tanks of the expeditionary vehicle and yet will respond instantly when needed.

Storable liquid propellants is one of the fields in which Rocketdyne has anticipated the future. For more than ten years, its propellant chemists have been studying, engineering, and testing combinations of storable fuels and oxidizers for greater storability and higher energy.

Storability PLUS high energy

Rocketdyne has tested these combinations in all production and experimental engines. The results prove that today's storable fuels and oxidizers have these important capabilities:

(1) High performance, even after months or years of storage; (2) Stability over a wide temperature range, permitting storage in missile tanks without rigid environmental controls; (3) Dependable performance, predictable even at extremes of heat and cold; (4) Instant readiness for firing at any time during the storage period; (5) Energy yields equal to or higher than those of conventional propellant combinations.



Second-generation missiles

The tests also prove that engines developed for conventional propellants can be converted to storable combinations rapidly and inexpensively—a significant consideration in the development of second and third gene tion strategic, tactical, and air fense missiles.

Significant, too, is the *potent* performance of storable combi tions. Research points to energy yie as high as 400 seconds of altitu specific impulse—performance 20 p cent higher than that of today's co binations. These high-energy yie will offer new capabilities and grea flexibility for America's scientific a military programs.

Stepping stones to Space

Rocketdyne has designed and bu much of today's operating hardwa in the high-thrust rocket field. E gines by Rocketdyne power most the military and scientific projec

Washington Countdown

IN THE PENTAGON

Davy Crockett is seen . . .
more and more as the Army's limited war weapon par excellence. *Davy*—an in-house project at Rock Island, Ill.,—is reported to be designed to carry a nuclear warhead of sub-kiloton yield. The still secret missile will be fired by a GI from a bazooka tube.

• • •

The Navy is pushing . . .
for a joint space command to operate the vast military space and missile facilities on the West Coast. Of course, such a command would include the huge new Pacific Missile Range.

• • •

Lack of missile ranges . . .
in Western Europe will lead to the increasing use of U.S. ranges for the training of European NATO missile units. Suggestions that France open up its Sahara Missile Range south of Colomb Bechar for NATO training have received a very chilly reception in Paris.

• • •

The cut in B-58's . . .
from 40 to 32 for FY '60 is only a sign that the bombers cost more than anticipated—not a sign that manned bombers are being phased out in favor of missiles—at least so far. The Mach 2 B-58 price tag: about $15 million each.

• • •

The codeword *Agena* . . .
is ARPA's new name for the orbiting upper stage of its *Discoverer* vehicle. The **Lockheed** upper stage is powered by the **Bell** *Hustler* liquid engine.

• • •

The smart money . . .
now is on an early September launching of an operational **Convair** *Atlas* from Vandenberg AFB. The successful launching of an *Atlas* from Cape Canaveral Aug. 11 appeared to cinch the matter.

ON CAPITOL HILL

The last act . . .
of the Hébert Investigation may not come until shortly before Christmas. The House subcommittee probably will adjourn its investigation of the so-called "munitions lobby" when Congress quits for the year—sometime in the next few weeks. The hearings then would be resumed about early December for an airing of some specific cases.

Congressmen are worried . . .
over the possible development by Russia of poison gas missiles. Experts have told the House Space Committee that chemical warfare could be as dangerous an all-out threat as nuclear war . . . and more advantageous to the enemy.

AT NASA

NASA's deep space probe . . .
schedule this fall includes one moon orbit and one sun orbit. An attempt will be made to orbit the *Atlas Able IV* vehicle around the moon about Oct. 8—the date when the moon is farthest south. In December, NASA will attempt to send *Thor Able IV* to join *Mechta* and *Pioneer IV* as a miniature satellite of the sun, but with a transmitter which would send information to earth from as far away as 50 million miles.

• • •

Amateur hams and astronomers . . .
are furious over NASA's decision not to release the frequency of *Explorer VI's* big 40-watt transmitter. NASA contends that the frequency must be kept secret because it is one used by the military. The hams contend NASA released similar information on *Pioneer IV's* frequency. Among the protesters is a group of scientists at the Case Institute of Technology and **Standard Oil** in Cleveland. They have their own satellite tracking station and were one of the few western groups to track the Russian *Mechta*.

AROUND TOWN

Speculation is . . .
that the Soviets may try to strengthen the hand of Premier Krushchev on his U.S. visit by either orbiting the moon or sending man into space. The most favorable astronomical time for a moon shot would be a few days before the beginning of Krushchev's visit on Sept. 15. That would give the Soviets time to determine the success of the launching before the visit and "to time the announcement" with his arrival.

• • •

Sept. 5 is a likely time . . .
for the Russians to announce a manned space flight—simple ballistic trajectory. It's the birthday of Russian rocket pioneer Konstantin Ziolkovsky.

• • •

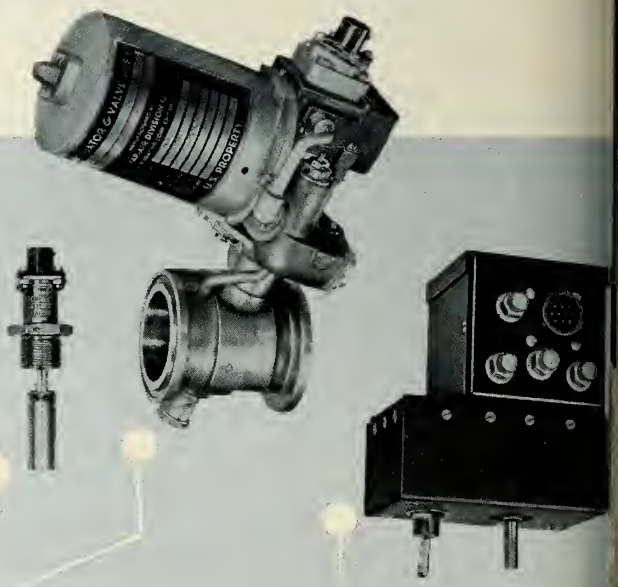
Shipments of *Nikes* . . .
will soon be heading for Denmark. The Danes are expected to be sent a total of 40 **Western** Electric *Nikes*—some *Ajax*, some *Hercules*.

VĀP-AIR'S YEARS OF EXPERIENCE CAN SAVE YOU HUNDREDS OF SPECIALIZED MAN-HOURS in solving critical thermal control problems

a case in point:

sophisticated problem:

AIR TEMP CONTROL IN MACH 2 MANNED CRAFT



Needed:

absolute accuracy under severe G conditions, light weight, safety in case of electrical failure, sensitivity throughout a wide ambient temperature spectrum, low initial cost, simple maintenance, interchangeable parts for 3 complete air temp systems:

cabin temperature
pressure suit
electronic compartment

NAVY A3J Vigilante
Mach 2 aircraft

simple solution

VĀP-AIR ELECTRO-PNEUMATIC CONTROL SYSTEM

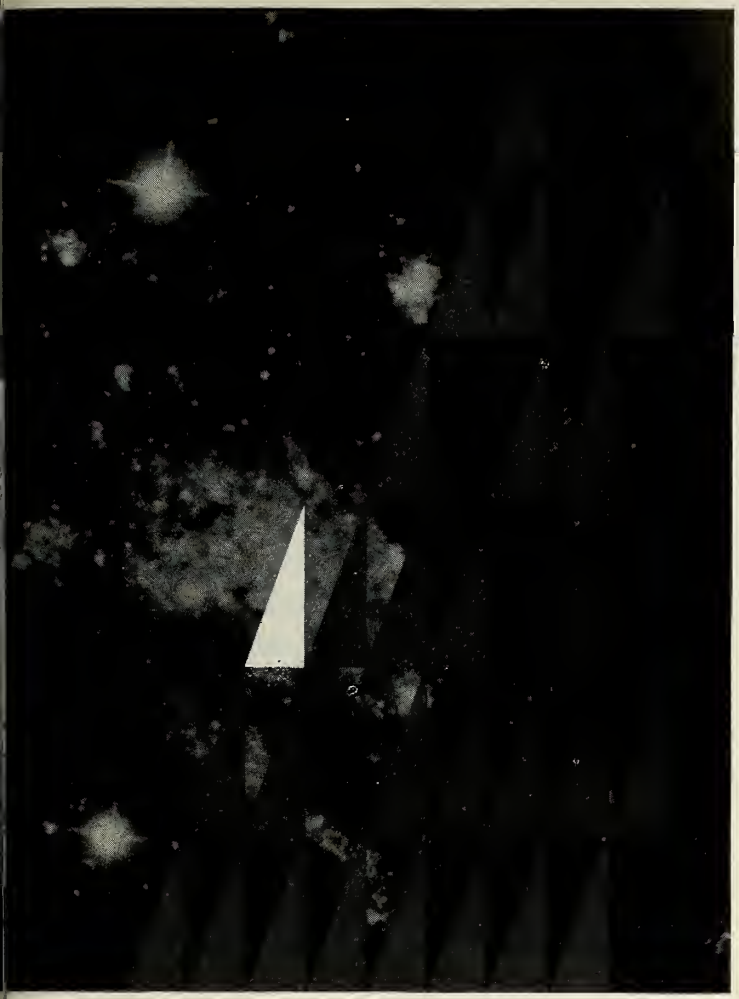
The 3 basic components shown at right, interconnected by VĀP-AIR designed electrical circuits met all these requirements...with response rates full open to full close of less than three seconds. Because all pick-ups and valves have the same resistance value, several systems for one craft can use the same parts!

DUCT TEMPERATURE SENSOR
One of many types made by Vapor, including thermistors, wire-wound resistance-temperature pick-ups, mercury contact thermostats, or the new MERCISTOR.

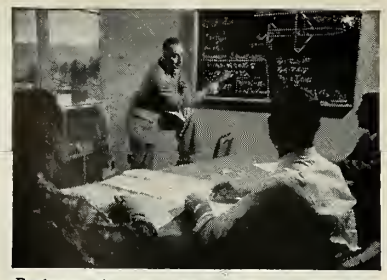
VALVE AND ACTUATOR
Two types: ON-OFF; or full-modulating, variable opening. Considerably lighter and smaller than electric valves, lighter than other pneumatic valves. Provides accurate hot and cold air proportioning. Other coaxial designs available for minimum envelope and rugged light weight.

CONTROLLER
Automatic or manual precision Magnetic Amplifier Power Controller acts as temperature controller, power converter, and transformer. Safe, simple, rugged, reliable!

CALL ON VĀP-AIR FOR SYSTEMS ENGINEERING AID WHENEVER A TEMPERATURE CONTROL PROBLEM ARISES:



AIR TEMPERATURE: Instrument & electronic compartments, cabins, cockpits, windshield and wing anti-ice.



LIQUID TEMPERATURE: All liquids, including fuel systems, batteries, exotic rocket fuels, H_2O_2, acids.

SURFACE TEMPERATURE: Anti-icing, de-icing, nacelles, primary heat exchangers, generators, alternators, canopies, bearings, gyroscopes, accelerometers.

Detailed data and problem analysis for those who design for flight. Write on your letterhead, specify type of equipment or nature of problem.

Environment for Dynamic Career Growth

for Engineers and Scientists

Ability is important in getting ahead in engineering and science. But of almost equal importance is the environment in which you work. A dynamic environment that provides challenge and scope, unexcelled facilities, and plenty of room at the top, can accelerate your advance to higher levels of responsibility and income.

This is the kind of environment you'll find at Boeing... pictured and described in Boeing's new 24-page booklet, "Environment for Dynamic Career Growth."

The booklet, in addition, reports on engineering and science assignments in connection with current Boeing projects—from advanced military and commercial jet aircraft to space vehicles, guided missiles and intercontinental ballistic missiles. It also outlines Boeing research and development activities, and documents the dynamic Boeing environment that fosters career growth of engineers and scientists.

There are openings at Boeing, now, for engineers and scientists of all categories, all experience and educational levels. A Boeing assignment in Research, Design, Production or Service could be the answer to *your* future.

DELIVERED—thousands of missile APUs

1. *Solid propellant—hydraulic output* 2. *Liquid propellant—hydraulic and electric output* 3. *Solid propellant—electric and mechanical drive out*
4. *Liquid propellant—hydraulic and electric output* 5. *Solid propellant—hydraulic and electric output*
6. *Solid propellant—hydraulic, electric and steering outputs*

AiResearch has designed, developed, manufactured and delivered thousands of missile accessory power units. Extremely reliable and lightweight, these various solid and liquid monopropellant APUs are completely self-sustaining within the missile system. Designed to minimum space and weight requirements, they are built to withstand high G loading and severe temperature extremes.

The several units pictured above provide hydraulic, electrical and/or steering surface control depending on the customer's requirement. Delivered horsepower ranges from 1.2 to 35 h.p. over hot gas operating durations from 30 seconds to 20 minutes. Electrical regulation is maintained as closely as ±½%. A significant advance in missile APUs is unit #6 pictured above. This package represents the first integrated hydraulic and electrical power unit providing a steering surface actuation syst

These tailored systems utilize extensive hardware experience complete laboratory, test and pro tion facilities of AiResearch nee for quick and efficient quan production of complex APU syste AiResearch is the world's largest most experienced manufacture lightweight turbomachinery — the component of its APU systems. Y inquiries are invited.

SYSTEM DEVELOPMENT CORPORATION

is currently seeking scientists and engineers in various skill areas. As part of this effort, I have been given the opportunity to tell you something about our organization.

Let me begin by giving you some general facts about the Corporation: SDC is a non-profit organization chartered to work in fields pertaining to public welfare, the advancement of science, and national defense. The Corporation's name implies its function—the development of systems. Specifically, we are concerned with large, complex information processing systems with a high degree of automation. Development of these systems is accomplished through the application of knowledge in the areas of applied mathematics, engineering, and psychology, to problems of over-all system design, data processing techniques and optimum man-machine relationships.

Our work is system-oriented, rather than concerned with the design or manufacture of hardware components. As a result of this type of specialization, we have assumed major responsibilities in the development of systems such as the SAGE (Semi-Automatic Ground Environment) Air Defense System and the world-wide Strategic Air Command Control System, and in the integration of the functional responsibilities of these systems with other military electronic support systems.

Because the scope of our activities is rapidly increasing, we are expanding our staff. In this message I am specifically addressing young engineers with advanced training and proved analytical ability in the areas of weapons system analysis, noise and information theory, ECM, electromagnetic intelligence and allied fields. If you are qualified, and our corporate activities sound interesting to you, we would like to hear from you. Address inquiries regarding our Santa Monica, California facility to Mr. R. W. Frost, 244 Colorado Avenue, Santa Monica, California. Inquiries regarding our Lodi, New Jersey facility should be addressed to Mr. R. L. Obrey, Box 2651, Grand Central Station, New York 17, N.Y. These gentlemen will see that your letter receives prompt attention and confidential treatment."

Industry Countdown

MANUFACTURING

Total of 6000 *Sidewinders* . . .
will be produced in Europe—5000 by **Bodenseewerk Perkin-Elmer** of Ueberlingen, Germany. The air-to-air missiles will go aboard **Lockheed** F-104G's, which are being bought in quantity by West German Air Force. *Nord* 5103 will be standard armament of **Fiat** G-91 lightweight fighters also being supplied to West Germany.

• • •

Still alive. . . .
transpiration cooling for re-entry. **General Electric's** Missile and Space Vehicle Department, Philadelphia, is devoting considerable research effort in this direction. Needed: proper materials.

• • •

All-out campaign . . .
for missile business is being cranked up by **Bethlehem Steel.** Despite late start, company figures it soon can equal and pass **U.S. Steel's** present lead in field of high-strength, high-temperature steels.

• • •

New Pacific press brake . . .
(with 500-ton push) is being used by **Boeing Airplane** to hasten developments in titanium and other high-temperature metal shaping.

• • •

Re-shaping *Titan* nose cone . . .
for faster re-entry is called for in $73 million Air Force contract awarded **Avco's** Research and advanced development division. Aim is to nullify enemy countermeasures. New design will require development of materials with greater heat tolerances.

PROPULSION

Multi-vehicle lunar . . .
expedition will have greater chance of success in the opinion of ABMA's Dr. Wernher von Braun. He proposes that instead of single vehicle, the operation include about six *Saturn* vehicles to serve as tankers for a seventh, which would carry a returnable payload.

• • •

Industry can solve . . .
orbital refueling problems, says von Braun, if it devotes all the engineering attention they require. The rocket expert says all three military services and NASA would have to pitch in together on logistical support of a moon mission—much like the all-out Navy support of Admiral Byrd's South Pole expedition.

ELECTRONICS

Inside word has it . . .
that both operational *Atlas* and *Titan* ICBM's originally scheduled for gas-turbine APU's will have to fall back on battery units. Reason: Inability to meet extreme design specs within development time allowed.

• • •

Difficulty in getting . . .
"on target" with narrow band (7°) radar is causing modification of Pacific Missile Range's FPS-16 tracking radar to incorporate optical acquisition.

• • •

DOD now is standardizing . . .
environmental requirements for electronic components. MIL-STD-446 sets forth eight "discrete levels" of environmental conditions applicable to equipment and component design. In the past, parts have been designed to withstand random conditions. Standard also is aimed at ultimate reduction of multitude of electronic items entering military supply channels.

WE HEAR THAT—

Latest wrinkle in . . .
hydraulic fluids is a metal with low melting point. Fluid would be held by metal seals perhaps at 1000°F and 6000 psi . . . Joint French-German research center at St. Louis, France, is being modernized. Facility dealing primarily with ballistic problems is 50-50 proposition with two chief execs—one German and the other a Frenchman . . . Although delivery isn't required until next year, **Bristol Aircraft Ltd.** has just supplied Sweden with the first of a batch of *Bloodhound* surface-to-air missiles to facilitate training program for initial unit to be located at Norrtälge . . . Need for working as well as equity capital brought on merger of **C. T. L. Inc.,** creator of first U.S. ablation re-entry nose cone (for *Jupiter),* with **Studebaker-Packard**—which is now diversifying into the missile industry . . . **General Electric's** Lamp Metals and Components Department, Cleveland, is offering pure molybdenum "HD" sheets with five times the room temperature ductility of ordinary moly . . .

• • •

Molybdenum has cut the price of consumable electrode "Climelt" pure moly and moly alloys from $9.85 a pound to $8.00. . . .

(Continued on page 40)

NEWS IS HAPPENING AT NORTHROP

Radioplane drones shown left to right: XQ-4B; RP-76; RP-77D; OQ-19; SD-1

RADIOPLANE CREATES FIRST FAMILY OF UNMANNED AIRCRAFT TO TRAIN MEN, EVALUATE WEAPON SYSTEMS, AND SURVEY ENEMY TERRITORY

Radioplane is the world's leading producer of drones and space age recovery systems. As live targets, drones perform as aircraft–then can be recovered by parachute. As evaluators, drones simulate the appearance of the enemy threat while they score our weapon systems' effectiveness. On surveillance missions, drones are zero-length launched, fly cameras, take photos, and return with information within minutes.

For 20 years Radioplane has led in the production of drones. Radioplane's leadership in the field typifies the years-ahead thinking that continues to produce design concepts for tomorrow, hardware for today–developed, produced, and delivered on time – at minimum cost to the taxpayer.

East Fights for Missile Dollar

Business booms in the New York industrial complex but area has yet to receive big prime missile contract— battle with California grows hotter in congress

by William E. Howard

NEW YORK—Inside the East oast's huge industrial complex sprawl- g from New York to Philadelphia, issiles today are big business. But ere are strident complaints that they ould be much bigger.

Missile manufacturing tops $1 bil- on a year in New York—yet the state oes not have a single major missile ime contractor. Some congressmen aim bitterly that California is getting r more than its rightful share. They e now fighting for legislation to roaden" geographical distribution of efense procurement. (California is ghting back.)

Over in New Jersey, despite the ck of a prime missile systems con- act, the picture is brighter. **Radio orporation of America** is prime con- acting BMEWS for an estimated 440 million and is heavily engaged radar, missile guidance and other ork, including test equipment for the rmy's anti-aircraft *Hawk*. And the ate generally is packed with missile omponent and electronic production.

At Philadelphia, **Philco Corp.** is co- ime with **General Electric,** Utica, .Y., on the Navy's air-to-air *Side- inder*. GE's Missile and Space Vehicle epartment in the "City of Brotherly ove" holds over $100 million in con- acts for *Atlas* and *Thor* nose cones nd the *Discoverer* satellite re-entry ehicle.

Throughout this industrial "heart- nd" there are scores of big and little rms hard at work on large missile sub- ontracts. Across Pennsylvania to ittsburgh, through "upstate" New ork to Buffalo and out on Long sland there are many more.

Defense Department procurement gures indicate that the total for all issile-related spending in the three- tate upper mid-Atlantic region is $3 illion or more.

• **New York slipping**—But industrialists and lawmakers fear that unless prime missile/space contracts are brought into the area, the industry will shrink. They point out that in 1961 missile appropriations very likely will equal the amount for manned aircraft, and after then, missiles will exceed aircraft spending.

One Long Island banker notes that during the Korean War, New York firms received 15.3% of the dollar value of prime contract awards, against 13.6% received by California firms. For fiscal 1958, New York slipped percentagewise to 11.6% while California climbed to 21.4%.

What does this mean in money? The banker says the shift in percentages when applied to huge missile programs translates into one billion dollars more for California than for New York.

Sen. Jacob K. Javits (R-N.Y.) puts it this way:

"At the present rate of acceleration, and with nearly $10 billion in prime missile contracts already awarded to California, New York can fall more than $3 billion behind California in defense procurement by 1961 . . ."

Javits is co-sponsor along with Sens. Kenneth B. Keating (R-N.Y.) and Clifford P. Case (R-N.J.) of S.1875, a competitive procurement act which they believe will have a scatter effect on future placement of missile contracts. At a Senate Armed Services subcommittee hearing last month on the measure, Javits declared that only $3.5 billion—15%—out of total defense procurement orders values at $23.8 billion is presently placed through competitive, formally advertised bids. And he added, "the proportion of negotiated contracts seems unusually high."

An aide of Sen. Javits commented to M/R this week that he had found the percentage of negotiated contracts "has increased with the number of retired military officers hired by defense contractors." He conceded: "This could be coincidence, of course."

• **Wants more open bids**—S.1875 spells out a Congressional directive to the Defense Department to replace negotiation with open bidding where there is no danger to national security. It would give prime consideration to small business; to concerns in labor surplus areas and to "eligible suppliers who have received the smallest share of business as well as being in different geographical areas of the nation."

Aerospace Industries Association opposes the Javits bill.

New York's congressional delegation touched off a transcontinental battle when they mounted a bi-partisan drive this year behind the competitive procurement bill. Californians retaliated in Congress. The Los Angeles Chamber of Commerce formed an "industrial task force to defend California's missile and aircraft defense business from further attacks by New York and other eastern legislators." The LA chamber has produced what New Yorkers call a "slick magazine presentation" detailing the state's "qualifications" for continued defense business. It is being distributed on Capitol Hill.

West Coast newspapers have added to the furor by implying the New York campaign is part of some strategy by Gov. Nelson Rockefeller to wrest the GOP presidential nomination from Vice President Richard M. Nixon, a Californian.

New Yorkers refuse to accept arguments that their state receives just as much missile business through subcontracts even though the prime is in California. They say subcontracting is erratic and that to build a stable missile industry New York should have prime systems contracts.

stubborn labor surplus . . .

• **Long Island growth**—While the verbal battle continues (no action is expected on S.1875 this session) New York industry is moving to snare a prime contract. **Grumman Aircraft Engineering Corp.,** principal subcontractor to the Navy *Eagle,* is in a $4 million expansion program. The firm is building a 55,000-square-foot center for complete avionics systems test, evaluation and development.

Recipient of military contracts exceeding $271 million in the past 12 months, Grumman's major production is aircraft for Navy anti-submarine warfare. It has created a small army of vendors in the state to which it paid $45 million last year.

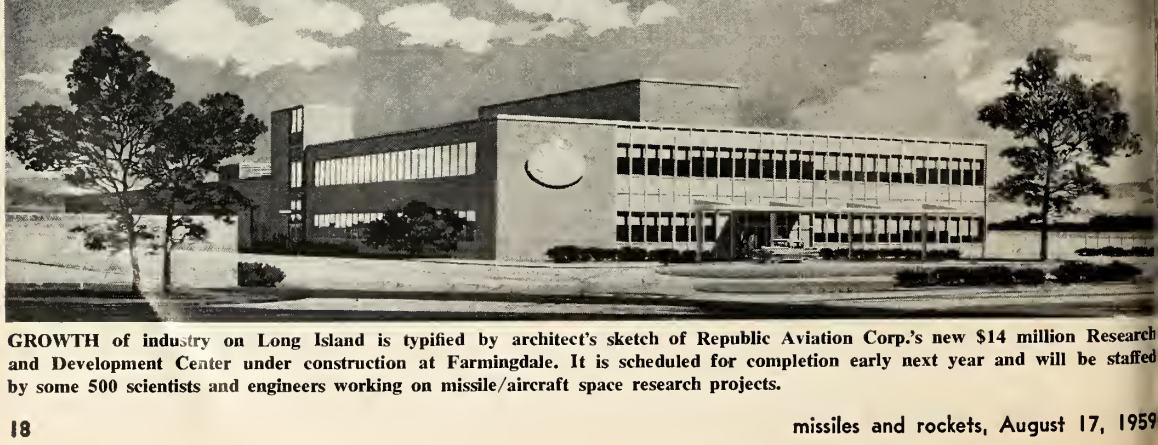
Republic Aviation, the Island's other big aircraft company (F-105 interceptors) is constructing a $14 million R&D center and has under full steam a missile/space research program valued at $35 million. One Air Force project is trying to determine what vegetables will grow on the moon.

The state's two other aircraft concerns have hit rough going. **Fairchild Engine & Aircraft** sold a Long Island plant recently after cancellation of the Air Force *Goose* decoy missile. **Bell Aircraft** at Buffalo as a result of a cutback in military work has let go about half of its 12,000 employes in the past 18 months. Last week, however, the firm picked up three AF R&D contracts totalling $575,000, including one for developing a storable propellant flow system for rocket engines.

Sperry Rand Corp. is in the vanguard of Long Island's fast-expanding missile component industry. One division, **Sperry Gyroscope,** has been steadily enlarging facilities and its work force to produce SINS (ship's inertial navigation systems) for *Polaris* submarines; **Ford Instrument** is turning out computers for Navy *Talos, Tartar* and *Terrier* missiles and guidance controls for the Army *Jupiter.* In the past fiscal year Sperry has received defense awards exceeding $220 million.

Other vital missile systems and ASW devices are being developed and produced by **Hazeltine Corp.,** which has just purchased **Wheeler Laboratories** in New Jersey and which is now setting up a 50,000 square foot engineering laboratory on the Island.

Dynamic Gear, producer of miniature precision gears for missile guidance systems, is building a $200,000 plant at Amityville. At Westbury, **IMC Magnetics Corp.** (electro-mechanical missile components) is doubling its plant capacity. **American Bosch Arma,** Garden City, developer of missile fire control systems and space vehicles is one of the Island's leaders with $66 million in defense sales in the past year.



• **Missiles upstate**—There is considerable missile activity in metropolitan New York among such firms as **Yardney Electric,** which rolled up second quarter sales of $1.6 million with auxiliary power units (silver-zinc and silver-cadmium battery systems) for missiles, satellites and torpedoes. The company also is involved in ASW research and production. **Computer Systems Inc.** is developing tracking computers and plotters for the Pacif Missile Range, Point Mugu.

Just outside the city, **Stauff Chemical's** eastern research center Chauncey, N.Y., is working on mon propellants for the Navy; at Whi Plains **Chromalloy Corp.** is pushir explosive forming of refractory meta under a "substantial" Navy contra and **Polytechnic Institute of Brookly** is trying to come up with the answe for WADC as to why plastics crack i space environments.

Upstate at Poughkeepsie and King ton, **IBM** is making automatic dat processing machines and computer totalling some $140 million for mil tary customers.

In addition to its Utica *Sidewinde* operation, **General Electric** is makin high power acquisition radar for th improved *Nike-Hercules* and *Atla* guidance at its Syracuse plant. G New York plants have received cor tracts totalling some $160 million sinc July 1958. At Rochester, **Eastma Kodak** is fuzing and arming *Sidewinc ers* and *Sparrow III;* in nearby Corning **Corning Glass** is developing glass ceramic materials for nose cones. I the Buffalo area **American Machin & Foundry** is manufacturing *Titai* launchers and **Alco Products Inc.** i principal subcontractor of JATO meta parts for the Army's *Honest John.* An other Syracuse company, **Carrier Corp.** is a principal supplier of air condi tioners for missile systems.

There are hundreds more missil subcontractors all over the state. Bu officials say there are still surplus labo areas, notably around New York City This is why they are keeping up th battle to obtain some prime missil contracts.

GROWTH of industry on Long Island is typified by architect's sketch of Republic Aviation Corp.'s new $14 million Research and Development Center under construction at Farmingdale. It is scheduled for completion early next year and will be staffed by some 500 scientists and engineers working on missile/aircraft space research projects.

AF Wants Extra Billions for Space

It seeks to outstrip Soviets in third generation ICBM, military satellites, maneuverable spacecraft, ALBM and moon bases

SYMBOL of Air Force space effort is *Discoverer*, **the forerunner of the** *Sentry*.

Behind closed doors in the Pentagon, the nation's top military men are orking out the defense budget for FY 1961. Its effect on the nation's missile d space programs will be tremendous. Here is the first of a series of ticles on how the military men are thinking. NEXT WEEK: Navy planning.

by James Baar

WASHINGTON—The Air Force uld like to find two things in its cking this Christmas:

• An extra $5 to $7 billion for mis- e and space R&D.

• Much greater authority over the tion's space programs.

It won't get either. And it doesn't pect to get them. But both are ex- mely important to bear in mind. ey are strongly felt needs. And they m the parameters within which Air rce missile and space planning for e early 1960's is taking place.

Many Air Force officials see the xt several years as a great second nping off point in the East-West race r missile and space leadership.

They feel that R&D work done—not done—in these years could well termine the fate of the United States the late 1960's and early 1970's. herefore, they feel that the Air Force ould be permitted to push forward the job vigorously and unstintingly.

Here are some of the key missile d space systems that a number of r Force experts believe must be deloped as rapidly as possible:

• Reconnaissance, early-warning d communications satellites.

• The *ALBM*, the air-launched ballistic missile—and its strategic partner, a nuclear-powered bomber.

• A third generation *ICBM* to succeed the **Boeing** *Minuteman*.

• A maneuverable, recoverable space vehicle.

• A space vehicle capable of rendezvousing with another vehicle or pieces of equipment in space.

• Establishment of bases in space and on the moon.

Early types of all three of the satellites are already being developed under the direction of ARPA. The Air Force is developing *Midas* and *Sentry*. The Army is developing *Courier*.

Lockheed's *Sentry* will evolve from the *Discoverer* series of satellites. It is being designed as a long-life, unattended reconnaissance satellite.

Lockheed's *Midas* would provide early warning of *ICBM* attack. The satellite, through use of infrared sensors, would be capable of reporting the launching of an *ICBM* before it left the launching pad.

Courier, primarily an in-house project, is the first of a series of communications satellites. It will be a delayed repeater system. Later, active repeater satellites are planned for stationing in 24-hour orbits.

Douglas Aircraft is still working on design studies for the *ALBM*. However, it is hoped that development can begin moving forward by the end of the year.

• **Delays in** *ALBM*—Many Air Force experts regard the *ALBM* as one of the top weapons of the mid-1960's—particularly when placed on nuclear-powered bombers.

The bombers, armed with possibly eight *ALBM's*, would be placed on station for long periods, much like *Polaris* submarines. *ALBM's* could be launched 1000 to 1500 miles from their targets.

New delays in the nuclear-powered plane program have forced the Air Force to shelve this strategic idea indefinitely. Meantime, the *ALBM* is being designed for launching from Mach 2 B-58's and Mach 3 B-70's.

The *ALBM* also is seen as the progenitor of the space-launched missile. Such a weapon would be launched from either a maneuverable space craft or a satellite.

• **Shape of third generation**—The Air Force has yet to decide on the specific requirements for a third generation *ICBM*. They probably will be written within the next six months or a year. However, the general nature of these requirements is clear.

The Air Force candidate for successor to *Minuteman* will ideally be lighter and somewhat smaller. It will have extremely accurate guidance. It will be easier to control and may be capable of changing course. It will pack bigger warheads.

money is the prime problem . . .

The solid *Minuteman*—expected to be operational about early 1963—is about a third the size of the huge liquid **Martin** *Titan* and **Convair** *Atlas*.

It is designed to be fired from hardened underground sites where it can be kept for long periods. It also will be designed for firing from railroad cars and large vans.

However, *Minuteman* packs a much smaller warhead than *Atlas* or *Titan*. And although its guidance will be improved it will be able to fly only a predictable ballistic path like its predecessors.

The third generation *ICBM* will be a far deadlier and trickier weapon.

Its guidance will enable it to score a direct hit on any hardened site. U.S. experts agree that not even a hardened site can withstand a direct hit by a nuclear warhead.

Its ability to maneuver will enable it to avoid attempts to stop it with an anti-missile missile. Its improved control system will enable launchers to direct it to a variety of targets while it is in flight.

Its relative lightness and size will greatly increase its mobility. Its bigger warhead would eliminate the need for continued maintenance of the first generation missiles in the nation's strategic arsenal.

Finally, the development of such a weapon probably would lead eventually to abandonment of fixed, hardened *ICBM* sites.

Presumably Russia by this time also would have improved its guidance systems to a point where any known hardened site could not survive an attack.

• **Toward rendezvous**—*Dyna-soar I* is the Air Force program aimed at development of a maneuverable space vehicle. However, it is not in itself aimed at development of a weapon system. Rather, it is a research program.

Dyna-soar I, estimated to cost possibly $1 billion, would test out the concept of launching a space craft from the earth into orbit and returning it into the atmosphere at will and landing it.

Dyna-soar II, also known as *Mrs. V*, would be the true weapon system: A maneuverable, recoverable space bomber. It also would lead to a vehicle capable of rendezvousing in space.

Air Force officials feel that the ability to rendezvous in space will become essential in not too many years.

Unknown satellites will have to be identified. U.S. satellites will have to be repaired and re-equipped. Space stations will have to be built. And, finally, the stations will probably be used as staging areas for space exploration.

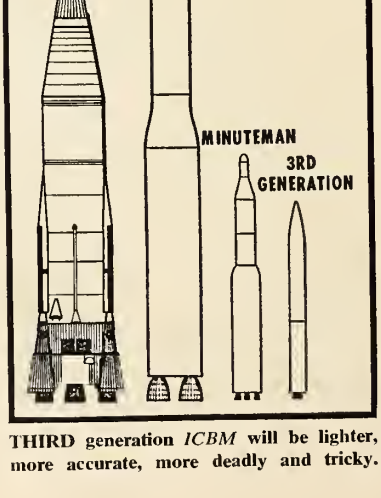
A number of Air Force officials feel that such stations also could serve as military bases in space. On the other hand, some feel that moon bases would be more efficient.

• **Robbing Peter**—All of these programs are running into the major obstacle of money.

The Air Force feeling is that as much as $5 to $7 billion more is needed each year. At the same time, the Administration has made clear that the Defense Department's budget for FY '61 will be the same as this year if not lower.

This means that much of the money needed for missiles and space must be found in other programs or not at all. For example, the Air Force might have to decide to drop development of the B-70—possibly a $10 billion program—in order to press ahead with development of *Dyna-Soar* and other space projects.

Or, the Air Force could be faced with losing a project like the B-70 anyway so that money can be found by the Defense Department to press on with new Army and Navy space and missile projects.



• **Private preserves?**—This raises what the Air Force sees as another major obstacle in the path of its space programs: Division of authority.

The Air Force feels that space is not divisable; that the Army and Na are encroaching on space and in eff impeding progress; and that the res is a net gain for Russia.

As one Air Force officer has put "Space is not a new ocean for Navy and it is not an artillery ra for the Army. There are too da many cooks."

The Air Force feels that beca the Army and Navy do not have same needs as the junior service, t will not push essential space progra as hard as the Air Force would.

Needless to say, both the Army a Navy have stiff counter arguments.

THIRD generation *ICBM* will be lighter, more accurate, more deadly and tricky.

NASA Official Proposes Outer Space Definition

WASHINGTON—How high does space extend, and where does ou space begin?

Dr. Robert Jastrow of the Natio Aeronautics and Space Administrati suggests that this important legal qu tion be settled by reference to or characteristics of a typical satellite.

Jastrow, chief of NASA's theore cal division, proposes that outer spa should be defined legally as the regi traversed by vehicles that have be placed in orbit about the earth, or t have escaped from the gravitatio attraction of the earth.

At low altitudes, a satellite quickly destroyed by atmospheric fr tion. To be considered an orbiting sat lite, Jastrow says, it should make least one circuit of the earth. Thus, suggests that air space be defined as t altitude at which the density of atm sphere is sufficiently low to permit c circuit.

"Our calculations of satellite li times indicate that this critical altitu is 100 miles for a satellite of a typi weight and dimensions, i.e., a weig of one ton and a cross-sectional area 30 square feet," he says.

New Compound Excels as Corrosion Inhibitor

COLUMBUS, OHIO—Ammonium h afluorophosphate is better than hyd fluoric for inhibiting the attack of fu ing nitric acid on several metal alk over an extended storage period.

Three **Bell Aircraft Corp.** searchers made this report recently a paper read at the American Roc Society conference on propellant th modynamics and handling.

Sam A. Long, William H. Bergd and Edward J. Kinsley tested 70 co pounds suggested as possible corrosi inhibitors. The tests ran for 30 days 120°F in liquid and vapor-phase con tions.

U.S. Liquid Hydrogen Stream Swells

Industry and government cooperate in building large tonnage plants to make 'ultimate' chemical fuel more than a laboratory curiosity

by Jay Holmes

WASHINGTON—Hydrogen, in the m of an odorless, colorless, frigid id—the lightest there is—has pro-ssed in seven years from a labora-y curiosity to the product of a good-ed industry.

Rocket fuel and research needs for liquid—which boils at –423°F—ve created a multi-million-dollar rket. And with increasing use of drogen as fuel for big rockets—be-nd *Centaur*—now in the thinking ge, the market is bound to increase.

Seven years ago, the largest instal-ions produced less than 15 pounds liquid hydrogen per hour. Today, daily production is measured in s. By next spring, the figure may doubled.

At the moment, three companies in the business of making liquid drogen on a large scale. **Air Products** . has built and operates a large nt for the Air Force at West Palm ach, Fla., and a moderate-sized nt at Painesville, Ohio. **Stearns-ger Manufacturing Co.** operates a derate-capacity plant at Bakersfield, lif. And **Linde Co. Division of ion Carbide** is building a large plant t will begin operation at Torrance, lif., next spring.

Production and cost figures on the Products and Stearns-Roger opera-ns are classified. The Air Force feels t revealing them would give a po-tial enemy valuable information on erica's war potential.

This creates an amusing paradox. r the Linde product will be sold to SA, the civilian space agency. Pro-ction and cost figures for this plant—ut as large as the Air Products ility in West Palm Beach—are a tter of public record. An Air Force kesman says classification of such rmation is under constant review l some of its hydrogen figures may released soon.

The creation of this new industry is an example of industry-government cooperation. Because it boils at 70°F above absolute zero, large-scale storage of the liquid has been a poser. Scientists of the Atomic Energy Commission and the National Bureau of Standards discovered principles underlying a process for storing the liquid without undue loss. Based on the scientific breakthrough, Air Products, Stearns-Roger and Linde developed mass-production methods. And **Pratt & Whitney Division of United Aircraft** has learned to handle the fluid in preparation for use as rocket fuel.

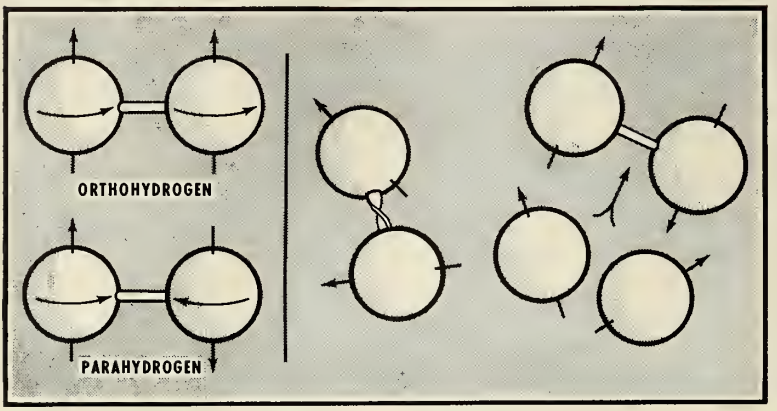
• **"Ultimate" chemical fuel**—The interest in hydrogen is mainly the result of its role as the ultimate chemical fuel. More specific impulse is provided by burning hydrogen than any other fuel—whether in oxygen, fluorine or any other oxidizer. The reason is elementary chemistry. Hydrogen, the lightest element, has one electron per atom available for chemical reaction. Since its atomic weight is 1, hydrogen has one reaction electron available for each unit of atomic weight.

When heavier atoms are used as fuel, there is no proportionate increase in the number of reaction electrons. Nor is there a proportionate decrease in the binding energy of the electrons, which would increase their reactivity.

Liquid hydrogen also has a role in *Project Rover*, NASA's nuclear propulsion development. Because of its light weight, hydrogen is best suited for use as a propellant gas to be heated by the *Rover* space-borne nuclear reactor.

The first plant with a capacity of more than 15 pounds per hour was put in operation by the Bureau of Standards at Boulder, Colo., in 1952. The liquid produced was kept in high-vacuum insulated, refrigerated dewars holding about 500 gallons (300 pounds). The refrigeration was necessary because the hydrogen molecule exists in two forms: one in which the two atoms are spinning in the same direction (orthohydrogen) and one in which they are spinning in opposite directions (parahydrogen).

Gaseous hydrogen at room temperature contains about 75% orthohydrogen and about 25% parahydrogen. But when cooled to the boiling point of –423°F, this mixture is unstable. At this temperature the two forms do not reach equilibrium until 99.8% of the molecules shift from ortho to para form. The diagrams on page 22 illustrate the transformation.



• **Long time transformation**—But the transformation from ortho to para requires a long time under ordinary conditions. It takes about a month for 25% para to convert itself to 90%. The conversion releases heat, because parahydrogen is in a lower energy state than ortho. It is more stable. This might be compared to some types of twin-engine airplanes in which the engines spin in opposite directions to make the plane more stable in flight by equalizing torque.

Because of this continuous release of heat, liquid hydrogen produced by older methods needed to be continually refrigerated. Even so, it was constantly boiling off. Many scientists searched for catalysts that would speed up the conversion, so that the product would be more stable.

The first major break came in 1953, when workers at the **Los Alamos Scientific Laboratory** succeeded in modifying a small hydrogen liquefier for the regular production of 85% para liquid at a rate of 25 liters (3 pounds) per hour. A short time later, the hydrogen liquefier at Boulder was modified to produce 240 liters per hour of 90-95% parahydrogen.

Meanwhile, under Atomic Energy Commission sponsorship, the Cryogenic Engineering Laboratory at Boulder began a catalysts research program directed by D. H. Weitzel. The most effective catalyst, they discovered, is hydrous ferric oxide. Its high conversion efficiency makes it possible to design ortho-para converters about 1/40

handling hazards are minimized . . .

HYDROGEN molecule exists in two forms shown at left: ortho, with spins of atoms parallel, and para, with spins in opposite directions. At right is sequence showing change of ortho molecule to the more stable para form.

the size of those used in the early work at Los Alamos and Boulder. This makes it possible to hold to manageable size the converters for the very large scale new plants.

• **12,000 pounds a day**—The Linde plant at Torrance, Calif., due to be completed next April, will have the capacity of producing 12,000 pounds per day. Linde, which is putting its own money into the venture, won't say how much the plant will cost. NASA has agreed to buy from Linde as needed on a sliding scale beginning at 70 cents a pound. If as much as 10,000 pounds a day are purchased, the price will average about 50 cents a pound, a Linde spokesman said.

Air Products Inc. began operating the first plant for continuous production of liquid hydrogen at Painesville, Ohio, in the summer of 1957. Stearns-Roger started up another plant the following winter at Bakersfield, Calif.

Part of the much larger Air Products facility at West Palm Beach went into operation in the fall of 1957 and the complete plant became operational early this year. It is the first plant with on-site generation of the gas used for liquefaction. As for production, the Air Force will say only that it is several tons per day.

Since the Air Force owns the plant and merely pays Air Products an operating fee, it would be difficult to give the cost of liquid hydrogen even if the figures were released. One officer has said that, depending on how you calculate, the cost is somewhere between $1.50 and $5 per pound. The Air Products contract for building and operating the plant is reported to be in the neighborhood of $20 million.

• **Vacuum-jacketed line**—A 2000' vacuum-jacketed pipeline connects the Air Products plant to an area where Pratt & Whitney tests the liquid hydrogen-lox engine that will be the second stage of the *Centaur* space vehicle. The pipeline is capable of transferring up to 400 gallons per minute (14,400 pounds per hour). Presumably, this transfer capacity is much greater than the Air Products plant's production. The line is used to supply pump test stands where 50,000 gallons (30,000 pounds) of liquid hydrogen may be consumed in one test.

The plant storage system consists of 28,000-gallon tanks (the number of these is classified). Vacuum-insulated trailers also are available for transporting 6000-gallon loads of hydrogen by highway to points in California and elsewhere.

The cold liquid, once thought to be extremely hazardous, now is considered only a moderate danger. Precautions are necessary but Air Products' safety director, Franklin Himmelberger, says it is less flammable than propane, commonly stored in tanks in rural homes.

P. C. Vander Arend, Air Products' chief scientist, has given this outline of the safety assumptions made in design of the plant: All equipment containing hydrogen gas or liquid, except for the compressor building six stories high and a quarter-mile long, is located outside, where leaking lightweight hydrogen will dissipate rapidly upward. All equipment containing hydrogen gas or liquid is kept at a pressure above atmospheric, to avoid contamination with oxidants. The same is true of cold boxes containing heat exchangers, adsorbers and liquid baths.

A rather extensive alarm syst tells when pressures drop below s limits and shuts down the compress if the conditions are not corrected. operator in a central control room a continuous visual and instrum check on plant operation. And entire liquefier and storage system closed. Under normal conditions, li hydrogen gas escapes into the atr sphere. Safety relief valves are pi into tall stacks, which are tigh covered except when the excess is ing vented.

• **Not too hazardous**—Engine working with liquid hydrogen ag that spills are not dangerous so l as there is no source of ignition. few gallons spilled will evaporate mediately. When hundreds of gall are spilled, the ground freezes, the liquifies and a cloud of ice crys and water vapor forms. Althou warm hydrogen is much lighter tl air, a large mass of very cold gas n have about the same density as and lie along the ground until it pi up heat. However, the adjacent outside the cloud has less than 0. hydrogen. Thus any explosion and will be confined to the volume of cloud.

A spill that is ignited immediat will burn smoothly in air without ploding. The fire creates an extrem strong updraft, so that damage usually confined to material direc overhead. Thus, C. D. Robin of P & Whitney advises, test stands sho be designed with no important equ ment overhead.

Leaks in a liquid hydrogen syst can usually be detected by the cl of ice crystals and water vapor arou it. But if the leaking hydrogen is bu ing, it may be harder to detect. hydrogen flame is invisible in daylig

Air Products recently invited engineers to its Allentown, Pa., he quarters for a series of lectures a demonstrations on safe handling cryogenics. Himmelberger told conference the three chief dangers handling liquid hydrogen are conta nation by oxidants, spills, and leaks the vent system. He recommended st preventive measures as periodic purg of vessels and pipes with inert gas, c stant monitoring of all equipment a powerful fans for quick evacuation all air from any room or building i which hydrogen may leak.

A constant alert is necessary, course, against the danger from spar flames and lightning. Hydrogen mal an explosive mixture with air when concentration is anywhere from 4 74%. "No smoking" must be the r anywhere near hydrogen equipment.

Engine Controls Demand A New Art

Components are improving too slowly to keep pace with new environmental demands; efforts to simplify servo loops underway

by Frank G. McGuire

Los Angeles—"The controls field s gone about as far as it can go h the materials and skills it has to rk with today—and we've pushed transducer and sensor business as rd as anybody." These words by ger M. DiJulio, Chief Engineer at **rvomechanisms, Inc.**, about sums up state of things in the field of engine ntrols, as seen by a number of comnies.

Components are being slowly but ely improved in reliability, performce, etc., but the problem is that they being improved *too* slowly. In ee years, say the controls people, 'll need much more performance an we have now in our control sysns. "But," they complain, "we'll be ked to make a system to operate at nus 400° F, and the same system ll have to operate at over 1000° F.

Other companies, specifically **Mardt Corp.** and **Bendix-Pacific Division,** are not trying to achieve seven-league steps as much as they are incrementally improving reliability and performance of present, proven components and loops.

Even though the performance and reliability have improved, there is a continuing effort to simplify the servo loops that make up a system for missile control. This is difficult mainly because of the basic nature of operating components. Many smaller items, such as a capacitor or two, have been deleted and some circuits have been simplified, but on the whole, no large-scale elimination or consolidation has occurred.

Certain important features have, of course, been designed into recent control systems, including that of **Aerojet's** *Titan* engine, which will continue operation even if the missile's hydraulic system suffers a complete failure.

Additionally, *Titan* is held to the launcher for a pre-determined period after full thrust is achieved, insuring that any malfunctions which occur immediately after ignition will automatically cause the engine to be shut off. The hold-down period, believed to be over five seconds, has been credited with saving at least one vehicle that was prevented from leaving the launcher at the last second, then was later flown successfully.

The unit is what might be termed a ground-based engine control, and is composed of a sequencer which compares the parameters of the engine operation with optimum parameters previously fed into it. If the actual engine operation does not fall within tolerable limits, the sequencer shuts off the engine before the missile leaves the ground. If all is well, explosive bolts are actuated, which free the missile for flight. The device's function is based on the premise that most mission-aborting malfunctions occur soon after ignition.

• **Thrust control**—In this area, the usual method is to sample chamber pressure through a transducer, and feed the error voltage through the control system into the servo loop, which regulates the turbopumps that either increase or decrease fuel and oxidizer flow until chamber pressure matches the pre-set level on the potentiometer of an electrical reference device.

Other methods of controlling thrust through propellant flow to the gas generator vary in complexity from a drilled orifice involving no moving parts, to the other extreme, with many electronic and mechanical devices in the system. Parametric requirements of the vehicle, calling for an accuracy between 0.1 and 5.0%, usually decide the method selected for thrust control.

With an open loop system, as normally used, each component must be made and tested to great accuracies, which is often uneconomical. If a closed system is used, the tolerances are more liberal, since the control sys-

Instrumentation Better Than Computation

"At this time, our instrumentation is much better than the computational art, and a lot better than circuits themselves. To be more specific, we can detect the motion of the sensing element in a transducer up to the limit of its internal hysteresis, where the properties of the material itself suddenly become a severe limitation. This is well below the confidence which you can place in things like precision gears, bearings and machined parts, synchros, and that sort of thing.

"We've developed some sophisticated and tricky methods to compensate for things like temperature and accelerations. But there's still a broad band of uncertainty that you can't trim out.

"This begins to suggest that a new art might be required here. This new art will be computation to higher accuracies. The first thing that comes to mind is digital computation . . . but the sensing of basic phenomena is an analog thing—and there isn't an acceptable transducer on the market today that will sense this analog physical quantity and put out a usable digital signal.

"Something basically new and different is required. It will not come necessarily from the controls people or the computer people, but will probably come from some physicist who studies the very nature of matter itself."

Roger M. DiJulio

Servomechanisms, Inc.

control for guidance accuracy . . .

tem can then account for any deviations. Since October 1953, when it was first proven possible by flight test, the thrust-controller has added considerable effectiveness to the missile.

With this thrust controller, which permits pre-planned trajectories to be actually flown in practice, the Army's *Redstone* has repeatedly followed the pre-programmed trajectories with a cutoff point within 100 milliseconds of its predetermined 110-second flight time. Accuracy in this case is within 0.1%.

One of the prime reasons for thrust control is accuracy of guidance, not merely for engine considerations of running at rated thrust. A great simplification of guidance problems results from closer control of thrust. The missile is programmed on a time basis, and the timing comes out right only when a precise trajectory can be flown as previously planned. If the thrust varies from the plotted ideal, the timing is off, and thus the angle is off and the vehicle's position in space is different than required for the mission—therefore the end-point of the warhead or other payload is not as planned.

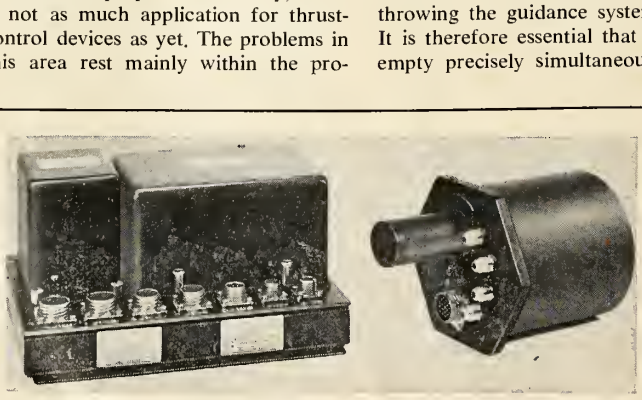
In order to correct for these variations, a much greater complexity of guidance systems would be required than is now needed for a closed loop thrust-control system where engine output is constantly monitored for compliance to the plotted level. It is therefore easier to make this a function of the propulsion system rather than the guidance system.

In solid propellant rocketry, there is not as much application for thrust-control devices as yet. The problems in this area rest mainly within the propulsion field, rather than the controls field. **Grand Central Rocket Company** has work in progress on a hybrid system that would control thrust levels by regulating the liquid oxidizer as it enters the combustion chamber with the solid fuel. **Thiokol Chemical Corp.** has indicated the possibility of introducing a combustion-modulating chemical that would disturb combustion to a controllable extent. Lowering of chamber pressure through escape ports at the side of the motor casing would also provide some means of thrust control.

Whatever the method used to actually raise or lower the thrust level in a rocket engine, the controls people indicate that present methods of exercising control and determining the amount needed would still be used.

• **Propellant utilization**—One of the most difficult problems confronting the engine controls people today is that of propellant utilization (PU) and liquid-level control. The difficulty lies in the accuracies needed, the environmental conditions encountered and the tactical requirements. Liquid-level control is a relatively old subject, but when applied to the measurement of rocket fuel/oxidizer levels, it becomes an entirely new field of endeavor.

Usually, the fuel/oxidizer combustion is done through stoichiometric requirements, so, that the PU system must insure that they are being consumed at an equally proportional rate. The most important consideration, therefore, is that the fuel/oxidizer must deplete simultaneously. Otherwise, combustion stops when the missile is lightest and near the end of powered flight, throwing the guidance system way off. It is therefore essential that both tanks empty precisely simultaneously.



The problem: continuous, pre
control and measurement of two l
masses of liquids, with great term
accuracy, in a vehicle travelling
12,000 mph and under terrific accel
tions, vibrations and temperature
tremes, and noise levels in excess
100 db. So, there are several sch
of thought on how it should be h
dled.

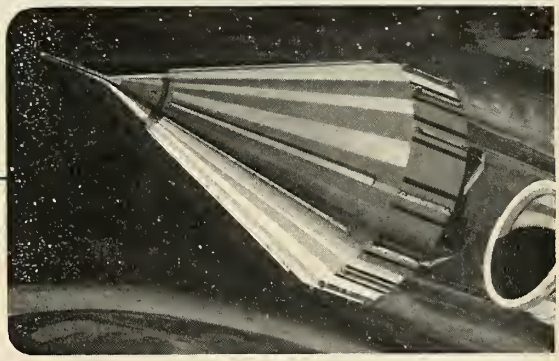
Historical Achievements at JPL

JATO UNITS... The nation's first successful jet-assisted takeoff (JATO) units were originated and developed in 1941 at the Jet Propulsion Laboratory, and sparked the development of future rocket vehicles.

THE CORPORAL... this country's first ballistic surface-to-surface guided missile, now an operational weapon of the U.S. Army, was pioneered and developed by the Jet Propulsion Laboratory.



EXPLORER I... The United States' first successful earth satellite, launched January 31, 1958, was developed by JPL in collaboration with the Army Ballistic Missile Agency.

THE WAC-CORPORAL... fired in flight from a V-2 rocket, established a world's altitude record of 250 miles in 1949. The combination was known as the Bumper-Wac.

THE SERGEANT... A second-generation solid propellant missile developed by JPL for the U.S. Army. The SERGEANT is now being readied for production.

PIONEER IV... America's first successful moon-space probe, launched March 3, 1959, was developed by the Jet Propulsion Laboratory in collaboration with the Army Ballistic Missile Agency and the National Aeronautics and Space Administration.

HOW SAC's "HOUND DOG" SCENTS ITS TARGET

The crew of the B-52G starts up the jet engine of the sharp-nosed GAM-77 Hou Dog missile hung under its wing... gives its inertial autonavigator the location of the targ

On a "for-real" mission, the Hound Dog would leap toward its target at supersonic spe —very likely a ground-defense center hundreds of miles away. Its guidance system can't jammed... can't be decoyed.

Purpose of the GAM-77 air-to-ground jet-powered guided missile is to increase the striki power of Boeing's B-52. Sling a pair of Hound Dogs under the wings of the new B-52G—a you have what amounts to a brand-new weapon system.

The GAM-77 program was started in August, 1957. The missile has been put into accelerat development. It already is in its early flight test phase... will be deployed by 1960.

Weapon system contractor: the Missile Division of North American Aviation.

MISSILE DIVISION NORTH AMERICAN AVIATION, INC., DOWNEY, CALIFORNIA

new system to do two jobs . . .

off and maintaining the desired level in face of evaporation. At launch, this computer is dropped to the pad and reused.

Servomechanisms is currently at work on a system which will do both jobs: control ground fueling and also airborne depletion of fuel/oxidizer tanks. The airborne device will gain negligibly in weight, since most of the changes from present equipment involve only wiring.

These systems are small and light and are basically independent of the type of liquids being used in the missile, because there is no direct contact between the sensor and the tank contents.

Complications in loading occur similarly as in utilization: tank diameter changes, fuel densities with varying temperatures, and varying densities between fuel and oxidizers. Even different batches of the same fuel have slightly different densities.

Then there is the problem of sheer size in the plumbing that must handle vast amounts of liquid. How can a vehicle like *Saturn* be adequately and accurately calibrated for fuel loading? The first stage alone holds three million pounds of propellants. There will be at least three, and possibly five, different fuels and oxidizers used in the vehicle.

The accessory requirements are just as stringent. Vibration requirements for transducers on *Saturn* first-stage are over 125 g. This is in addition to the temperature requirements needed for a vehicle using eight engines in the first stage.

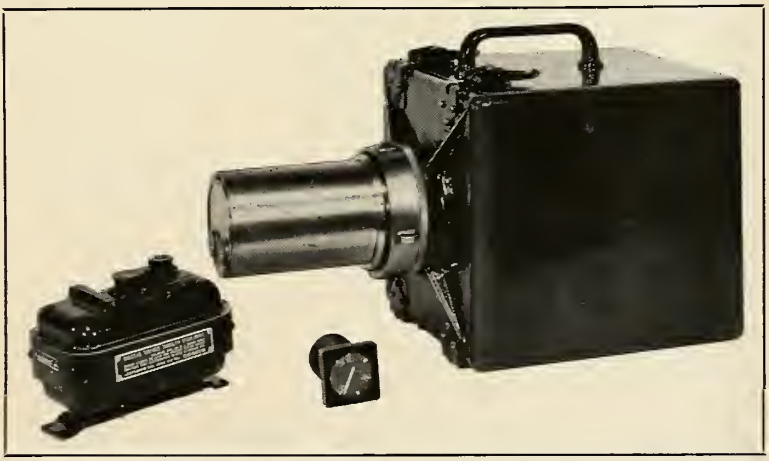
• **Hydraulics or pneumatics?**—The use of hydraulics or pneumatics in a system, depends, of course, on the requirements involved. Principal advantage of hydraulics being their good response characteristics, while their disadvantages lie mostly in temperature and nuclear radiation limitations. Gases suffer from a lack of response characteristics, but have few temperature or radiation worries.

The application of hot-gas pneumatic servos is getting considerable attention from Bendix-Pacific, which is using "clean fuels" as a hot-gas source. Company engineers feel that solid propellant gas generators, while having many advantages, introduce contamination to delicate systems. "Although solid-propellant people maintain their gas generators are very clean, and this is true in most senses, we find just enough contamination in them to justify using bottled cold gas where possible," explained a Bendix engineer. In reliability, also, Bendix sees the bottled gas as an advantage. It is viewed as competitive weight-wise with hot-gas systems, even for explorations as far as Mars. "It depends on how much you want to run the thing," says Bendix, "because cold-gas is superior to hot-gas up to about 1000 I_{sp}. Beyond that, the hot-gas systems seem to be favorable, except that they are not easily used in an on/off/on situation."

Response characteristics favor hydraulic systems, which perform at about 270 cps in an arrangement whose equivalent pneumatic system would perform at about one to five cps. Adding some sophisticated feedback to the pneumatic system would raise response to about ten cps, says Bendix, indicating that a factor of 25 to 30 makes the difference quite broad.

Marquardt Corporation, working mostly with pneumatics, has achieved responses of 18 cps, for example, then connected the system with external RC-type networks that reduced response to 3 cps. The change results from looking at the loop response or the complete system response. In contrast with Bendix, Marquardt has used hot-gas sources from either liquid-propellant or solid-propellant gas generators, but is not currently utilizing cold-gas bottled supplies to any great extent.

Work in the pneumatic system field is concerned mostly with improving "stiffness" of the system response, performance of individual components, and the old bugaboo, reliability. Few companies admitted to a search for one great stride or "breakthrough" in the field of controls.



Marquardt is working on the adaptation of new principles in gas systems, as well as component and loop improvements. Advanced work at Bendix is also in gas controls, although company spokesmen feel that hydraulics are adequate for anything now or in the future, ". . . but to stay competitive, we have to reduce size and weight and increase performance."

• **Pressure switch**—An example of individual component improvement is that afforded by Servomechanisms, Inc.'s new pressure switch; devices which have been the bane of design engineers' existence. They've been notoriously unreliable, unpredictable, hard to make, environment-sensitive, etc.

The switch recently designed by SMI operates on a novel principle which does not depend on the storage of energy, the release of energy, or the triggering of mechanisms. It depends on a very discreet electrical phenomena which is either black or white. The switching takes place over an extremely narrow range of pressure change, and with extreme rapidity.

The unit is very reliable and rugged, as illustrated by the description of one of its tests: "We can set it to within a fraction of a psi of the switch point, hammer nails with it, and the circuit will not switch . . . go up on the other side of the range, set it again to within one psi of a switch point, hammer some more nails, and the circuit still will not switch."

The accelerations and shocks are in the thousands of g's, but the unit still detects motions in the pressure element down to tens of micro-inches. The logic is all electronic, solid state, and the unit is encapsulated into a capsule about 1½" diameter and 2" long. One part has an elastic motion,

MAIN BUILDING block in obtaining a competely automatic propellant loading system is the LOX tanking computer system.

NEW PROGRAM

Raytheon enters new weapons systems program and offers advancement opportunities for both Junior and Senior electronics engineers with experience in the following fields:

- Microwave engineers—component and antenna design
- Communications systems
- Guidance systems
- Computer systems
- Radar systems
- Inertial reference systems
- Feed-back control
- Auto-pilot
- Ground support
- Electronic packaging engineers
- Radar systems engineers (project management)
- Electromechanical engineer for missile control and auto-pilot design (project management)
- Mechanical engineer experienced in ground handling of large missile systems (project management)

You and your family will enjoy the many advantages of living in the metropolitan Boston area. Relocation assistance and modern benefits.

Please forward resume to:

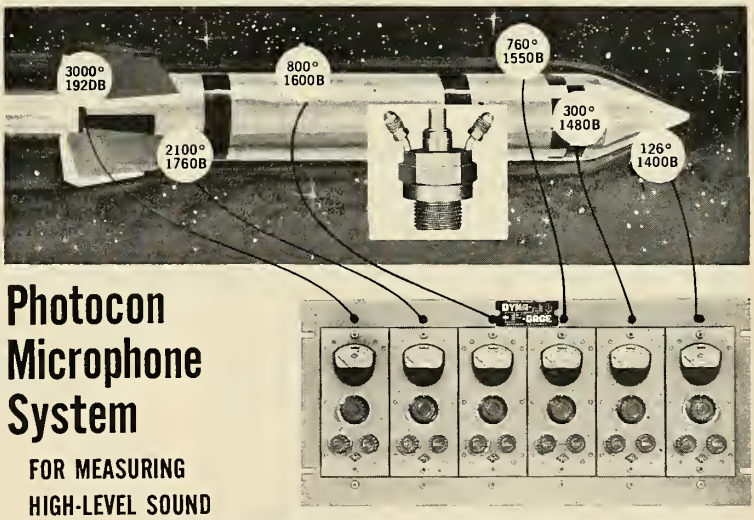
SERVOMECHANISMS' SMI Type AC 2019 computer with protective cover removed.

but there are no other moving parts. Operating with an on/off differential of 0.1% (it has achieved 0.03 of 1%), the switch will be used on the *Saturn* vehicle to sample chamber pressure in each of the first stage's eight engines, then signal a black box to release the vehicle if pressure is as planned. Otherwise, engine-cutoff devices will be actuated. As in most devices of this nature, fabrication of the devices is but a fraction of the time and cost involved in quality inspection, testing, and calibration.

• **Testing and accuracy**—Candidate for the title of most frustrating problem is that of proving just how accurate or reliable a device is. The standards are limiting, and there is a major obstacle in determining absolute accuracy. As phrased by one frustrated engineer: "We're talking about accuracies of 1/10 mm of mercury or less. We'd love to have a couple of hundredths of a millimeter, but we just can't get it." The problem is industry-wide . . . and is not just a technical problem. It has become necessary to organize the entire company, from front door to shipping dock, to handle that kind of accuracy. Sloppiness cannot be tolerated anywhere in the process.

Astronomical increases in performance will be required in the near future. Some of them can't be met right now. Frequently, say industry spokesmen, the specifications are written against what can be done, rather than what the requirement is.



One firm indicated that customers frequently come and say: "We need a gizmo to do this . . ." and is told; "You can't get it." "Then, we add a little increment to what is possible right now, and this makes us run for it."

It is estimated that systems managers could use another order or two of magnitude in the accuracy of propellant utilization, thrust control, and other segments of the controls field. The belief, however, is that the rest of the missile system is not that accurate, so the additional money we put into fantastically accurate devices is sometimes wasted. Tanks are not perfectly cylindrical, guidance is not precise enough, etc.

Then there is the argument that tolerances of a missile's components add up to a total probable reliability. Too many sloppy components, and the system will not perform. Therefore, each component must be much more accurate than the overall vehicle must be.

"It is sometimes necessary," said one Bendix engineer, "to compromise the design of one component to offset the weakness of another. In other words, you don't design the best servo valve, you design the best servo loop."

Complained SMI's DiJulio: "Everything we do now has a basic limitation . . . 'How accurately can we machine things?' 'How accurately can we measure them when they're made?' 'How stable are they?' 'Will they stay put until the vehicle gets there?' 'Can we get a production organization to make it?' and 'Can we get a production organization to determine that they've been made correctly?' So this problem backs up until you're down to the last girl on the production line . . . who never heard of the things you're talking about."

APU's—the Muscles for Missiles

Gas-turbines are first choice for missile auxiliary power units; batteries are a strong second; exotic sources still are some years away from reality

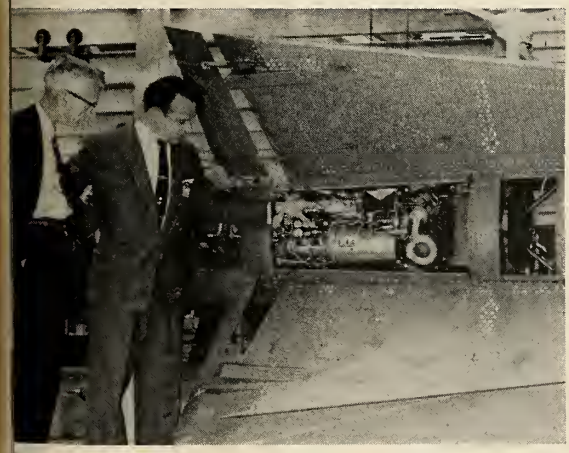
by Hal Gettings

WASHINGTON—A vital, but often neglected, part of a missile system is its auxiliary power unit (APU). These units supply electrical, hydraulic—and sometimes mechanical and pneumatic—power to the various operating mechanisms of the missile. They drive control surfaces, energize transducers, guidance, telemetering, and other accessory equipment. Their development and production is presently a $25 million business.

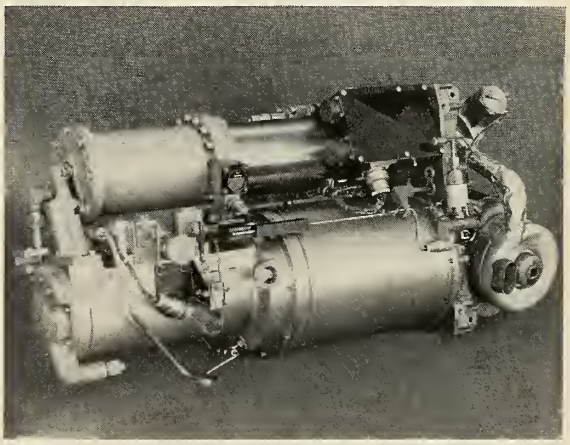
Differentiated from primary power—the missile's propulsion system—the auxiliaries perform a function just as vital to the mission's success. Whether a test vehicle or an operational type, each missile and space vehicle must carry a separate internal power source. This source may take one of several forms. It may be a fuel cell, thermoelectric generator, nuclear unit, or some other exotic form of power.

At present, however, two less glamorous sources are carrying the bulk of practical applications: gas-turbine APU's and batteries.

• **Gas-turbine**—The gas-turbine unit claims several advantages over the battery. Most important, it is more efficient in size and weight per unit of power output. Batteries have undergone a steady improvement, however, and they find use in many missile applications. A comprehensive report on their development and important place in the missile business will be covered in next week's issue of m/r.



Gas-turbine APU's use both solid and liquid propellants as a hot-gas source. Both have their advantages and limitations and, at present, neither is considered sufficiently superior to make it universal.



Current production of short-duration APU's is dominated by solids for their ease of handling and storage capability. For run durations of over two minutes, liquids are expected to dominate production for the next year.

Current research and development is aimed at solid-propellant units for over 30 hp and durations of up to 20 min.

According to an **AiResearch** spokesman, APU's can be expected to become more elaborate with each passing year. Power requirements and durations will continue to increase. He predicts that liquid propellants will be able to fill the need for units running for six months or more. Beyond one year, solar and nuclear-powered APU's will have to fill the need.

Generally, the liquid units are bulkier, more complex, and less reliable than the solids. On the other hand, their packaging design is more flexible and they are more controllable. Progress has been made in sealing the liquid container so that fueled units may be stored for two years and possibly longer.

LEFT: installation of APU in *Nike-Hercules*. RIGHT: new and simplified APU developed by AiResearch uses only half the valves and parts of conventional units. Operating on either ethylene oxide or hydrazine, the unit can be modified for use with solid propellants. Designed as an approach to a standard power source, the current model weighs 85 pounds and produces five horsepower for 7.5 minutes.

trouble with crash programs . . .

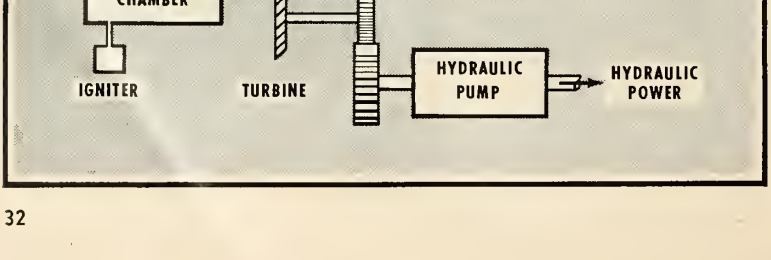
• **No emphasis**—Some auxiliary power manufacturers feel that proper emphasis has not been placed on this phase of missile development. They contend that the APU should be a part of the overall system design and not just packed into the missile frame somewhere along the line. Conversely, both **Thompson Ramo Wooldridge** and AiResearch—and possibly others—have made steps toward developing a line of standard units that would fit a large percentage of applications.

Since missile development is usually pushing the state-of-the-art, APU designers often find themselves working on a crash basis to build a unit for a particular missile. Consequently, new and unproven units are often pushed into production, or a missile development may have to wait for the APU.

Ideally, the APU development should go through an orderly process of feasibility study, research and development, breadboard, test and evaluation, and production. Such a logical time-consuming process would, of course, produce a good power unit for a now-obsolete missile.

This dilemma can be solved to an extent, however, by looking ahead to requirements for one to two years from now and doing the necessary research. In other words, start sooner. The problem here, naturally, is financing. Much could be accomplished by government backup of institute research programs in components and critical areas.

• **Areas of investigation**—Some of the areas to be investigated for improvement include evaluation of propellant characteristics, turbine reliability and efficiency, comparison of relative merits of various types of APU's versus application, materials for high-speed high temperature use, and standardization of environmental test requirements.



Many factors affect the design of gas-turbine APU's: type of control, outputs, run duration, package and space requirements, porting location, and others. They must be extremely rugged and reliable and be storable for an extended time. The primary problem of course, is the precise control of power output. Pressures, frequencies, power level are all critical.

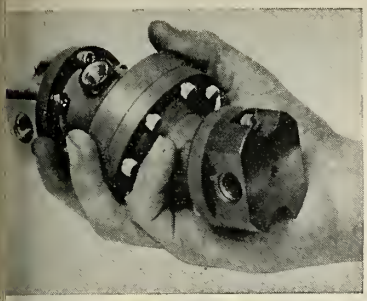
Strangely enough, most units are not designed for high turbine efficiencies. Usual figures run in the range of 30-50%. Better design could easily raise these to 70-80%. The output of one air-to-air missile APU was recently experimentally modified to produce more than double its previous output by a simply nozzle design change. NASA engineers at Lewis Research Center recently conducted an investigation of a 4.5″ two-stage turbine for APU use and obtained efficiencies of 65% and better.

Efficiency is usually sacrified, however, for reliability considerations. The smaller, more efficient, nozzle is more critical and subject to erosion and clogging. Especially in short-duration operation units, the gain in efficiency is usually not worth the cost. For long-duration operation (over 10 minutes) more attention is paid to higher-efficiency design.

Some work has been done on using primary propulsion gases to drive the power generators. Big problem here, however, is the difficulty in handling the extreme temperatures involved. At least one such system has successfully operated; others may possibly be in use.

Research has also gone into the possible use of hot-gas servos—a system whereby direct use is made of energy from a secondary or primary propellant. Such a system could be used in place of hydraulic power but would be no substitute where electrical energy is needed.

Claiming to be the largest manufacturer of APU's in the business, **Garrett Corporation's AiResearch Manufacturing Division** started work in the field in 1950. Current work includes units for *Terrier, Falcon, Nike-Hercules, Nike-Zeus, Polaris, Quail,* and an unspecified Navy missile. They are working on two WADC contracts for advanced space APU's—one using solar energy source and the other nuclear unit.



Thompson Ramo Wooldridge has several units now in operational missiles and others under development. They are producing a solid-propellant unit for the advanced *Terrier* BT- which is actually a double system. The hydraulic side produces approximately seven horsepower and the other about one kilowatt.

• **Hydrazine APU**—Their long-duration hydrazine APU for the *Bomarc* produces approximately 40 horsepower hydraulic and eight kilowatts electrical. This unit features completely sealed fuel tanks which can be stored upwards of two years. TRW last week introduced the first in a proposed series of solid-propellant multi-output electrical units which can be stored for as long as five years. They have also produced a solid-propellant turbo hydraulic pump, capable of about 1 horsepower output, for an unspecified missile. About half of TRW's units use solid and the other half liquid propellants.

Vickers Incorporated, in an extension of their work on hydraulic equipment, has just developed a unique hot-gas driven motor pump for use as an APU. This unit operates at moderate rotational speeds (6500-18,200 rpm) and produces ½ hp at 1500 psi and up to 66 hp at 3000 psi. The motor has reportedly been successfully tested using a hydrogen-oxygen fuel with combustion temperatures of over 5000°F. Because of its high temperature capability, the unit may be run from either propellant-generated gases or directly from the prime propulsion system.

The *X-15* manned missile uses two 40 hp hydrogen peroxide APU's which produce both hydraulic and electrical power. These units, built by **General Electric,** have an operation cycle up to 30 minutes and a designed life of 150 hours. Turbine speed is 51,200 rpm. Hydraulic pad speed is 3925 rpm and alternator pad speed 12,000 rpm.

Aerojet-General's Turbomachinery

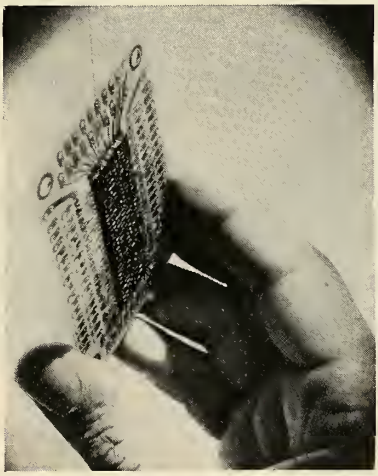
VICKERS hot-gas motorpump. Unit shown, smallest in series, is capable of 3.9 hp and weighs only 2.5 pounds.

Division, devoted entirely to APU work, has produced a hydrazine-fueled unit which develops approximately 30 hp. This unit, scheduled for the *Titan*, holds frequency and voltage variations to 0.25%. It has been test run for periods up to 1¼ hours.

A different type of APU used for extremely short-duration maximum-force power in many missile applications is the cartridge-actuated device (CAD). This device, which uses the controlled power of an explosion, can produce 50-100,000 ft-lbs per lb of weight. They are actuated mechanically (by a firing pin) or by heavy currents (two amps or more). They are used to activate batteries, engage and disengage gear trains, open and close switches and valves, separate components, shear cables and membranes, and unlatch aircraft missile launchers.

Other firms important in APU business include **Hughes, Raytheon,** and **Sundstrand.**

BIAX Units Expected to Replace Semiconductors



LOS ANGELES—A new microminiature computer element capable of operational speeds up to 20 megacycles per second has been developed here by **Aeronutronic Division** of **Ford Motor Company.** So small that more than 5000 can be held in a man's hand, the elements are expected to result in faster, smaller, and cheaper computing equipment.

Called the BIAX, the units are small (50 x 50 x 85 mils) bars of ferrite magnetic material presently being produced as memory elements and logic devices.

Several advantages are claimed for the BIAX elements over the semiconductor devices they reportedly will replace in the next generation of computers. They operate over a wide temperature range—from below freezing to 125°C. They have low thermal conductivity and are not affected by radiation. Units are relatively inexpensive to produce and reduce the number of solder connections in a typical computer by a factor of 10-100 and the number of connectors by a factor of ten or more. According to the company, an extremely high packing density may be achieved with the tiny units: 200 flip-flops and 3000 gates—the equivalent of 15-20,000 semiconductors—in one-tenth cubic foot.

The basic concept of BIAX is that of flux interference between orthogonal magnetic fields. This is accomplished by means of two 20-mil orthogonal holes through the elements. The flux interference takes place in the magnetic material between the holes. Because of the orthogonality, no normal magnetic coupling occurs between conductors associated with the two holes.

The spacing between the holes determines whether the flux interference is destructive or nondestructive. Nondestructive elements are used in memory applications and the destructive element in logic circuitry. In the memory elements, one of the holes acts as the storage axis while the other acts as the nondestructive interrogate axis. The logical element uses the same hole technique except that the holes are extremely close together.

TYPICAL BIAX array for an electronic digital computer memory unit, this printed circuit card contains more than 300 BIAX elements.

In memory element applications, BIAX provides a very rapid random access memory unit. Elements have been interrogated over 100 billion times at a ten mc rate with no loss in output signal.

Aeronutronic has five military contracts for equipment using the BIAX technique. Work is classified and no details are available.

Expanding the Frontiers of Space Technology in

RECONNAISSANCE

■ Lockheed Missiles and Space Division activities in reconnaissance are among the most advanced in industry. They include such areas as radar, optics, infrared and television. Work in the fields of radar and data link is concerned with research, design and development of systems and equipment for missile tracking, command guidance, detection and relay of information. Noise modulation techniques are under study as part of statistical communication theory and implementation of automatic space communication systems. Of special significance is the development of a radar firing error indicator that measures the intercept trajectory between target and attacking missile.

Solid state work in infrared embraces the development of new systems and subsystems for long range infrared communications, surveillance, range findings and target tracking. Considerable work is being conducted in optical devices and systems employing optics. Capability in this area also extends to scanners, encoders, detectors, read-out devices, and analytics of information processing.

ENGINEERS AND SCIENTISTS

Lockheed's programs reach far into the future and deal with unknown and stimulating environments. If you are experienced in work related to the above areas, you are invited to share in the future of a company that has an outstanding record of achievement and make an important individual contribution to your country's progress in the race for space. Write: Research and Development Staff, Dept. H-2-29, 962 W. El Camino Real, Sunnyvale, California. U.S. citizenship required.

AN AMERICAN AVIATION PUBLICATION

1001 VERMONT AVENUE, N. W., WASHINGTON 5, D. C.

tanford Plans to Build 42-Ft. Radar Dish Antenna

PALO ALTO, CALIF.—Stanford Uni-ersity and the Stanford Research In-itute will build a radar dish antenna tall as a 15-story building for studies the cosmos.

The 142-foot antenna will be the rgest of its type in this country and cond in the world only to the 250-ot dish at Jodrell Bank, England, e university announced last week. he Air Force Cambridge Research enter is providing financial support r the 1½-million-dollar project.

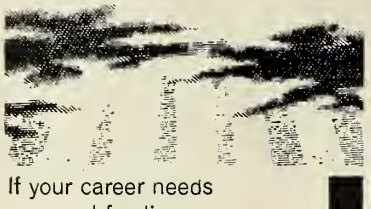
A million-watt radio transmitter—rgest ever built in the 20-60 cycle equency band—will be capable of uncing signals off the Sun and Mars. he gigantic research tool will be used make accurate measurements of anetary distances, explore the sur-ces of the Sun, Moon and planets d measure the rotation speed of enus.

lovel Technique May lass-Produce Transistors

BALTIMORE—A new technique de-loped by **Westinghouse** may pave the ay toward completely automatic mass-oduction of transistors and other miconductor devices.

Using long thin crystals of ger-anium, the devices are formed as a ntinuous series of dots along the sur-ce of the crystal. After electrical nnections are made, the strip is then t into sections, forming individual miconductor units. These are then aled in plastic or metal containers.

Westinghouse believes the entire ocess can be done automatically by achine at high speed and with highly liable results.



The Atlantic Ocean is the office of the Pan Am Engineer. Our Guided Missiles Range Division assists the Air Force in management, operation and maintenance of the Atlantic Missile Range. From our Division Headquarters at Cocoa Beach, Florida, to Cape Canaveral, the Bahamas, Ascension Island and beyond, members of our technical staff work and live by the sea.

Other creative engineers and scientists will find unique opportunities for professional achievement by the Atlantic Ocean with Pan Am. Address Mr. J. B. APPLEDORN, *Director of Technical Employment*, Dept. B-10.

missile business . . .

By WILLIAM E. HOWARD

It won't happen overnight, but the Army holds promise of becoming a considerably bigger market for basic and applied research work. Chief agitator for broadening industrial participation is Lt. Gen. Arthur C. Trudeau, chief of Army R&D. For some time now Trudeau has been calling for a step-up in basic research, which presently is funded to the tune of 5% of the Army's $9 billion budget. Applied R&D gets 45%.

In anticipation of a bigger program . . .
Trudeau's office is now in the process of preparing—for industry—a classified document detailing long-range Army research goals and problem areas, in which private research is needed. This document won't be ready for several months—perhaps not until next year. However, it should be an extremely useful guide when it appears—and well worth ordering in advance.

Even if Army research funding is not increased . . .
industry's share of the total may be greater. The Army is showing a tendency to break more and more research out of government arsenals. Maj. Gen. August Schomberg, deputy Chief of Ordnance, says that today his agency is spending about 20% of its money in-house, with 80% going to industrial plants and non-profit institutions.

Areas in which Trudeau sees a real need . . .
include "unexplored" alloys—to find those that will be stronger, more heat-resistant and lighter—and electronics. The Army is looking for surveillance drones to penetrate enemy air space and be capable of sending back information via infrared, radar, photographic film or television. And it is re-emphasizing aircraft that are "low and slow" and can take off like a helicopter. This area may be wide open for propulsion techniques that are being developed for rockets.

Just off the press is a new Air Force booklet . . .
telling about the broad applied research interests of the Air Research and Development Command—and how individual companies can go after contracts. The booklet (obtainable from ARDC at Andrews AFB) is called: "Applied Research Planning Document Release Program." As the title implies, this publication is a reference guide to applied research areas and contains applications for getting planning documents in specific areas such as propulsion, electronics, and metals.

These documents—like the Army's—are classified . . .
and companies must show a "need-to-know" to get them. This may present a problem for firms seeking to break into the defense research field. The documents are classified because they actually define the military problems involved and why the particular service wants to solve them. As such, they are a fair indicator of our technological progress and would be useful to Moscow.

Small business vs. big business over defense contracts . . .
is heading for a showdown in the next session of Congress. The tussle will come over S. 2487 introduced by Sen. George Smathers (D-Fla.), chairman of the Senate Small Business Procurement Subcommittee which investigated "abuses" by large contractors. Smathers contends several large contractors are guilty of pirating engineering know-how from small firms and are making more and more components themselves, rather than subcontracting items.

Coming up before Senate Armed Services Committee . . .
Smathers' bill would provide for more careful screening and contract review by the Small Business Administration of agreements letting private industry use government-owned production equipment; require a fair market rental on such facilities; keep SBA fully informed of major contracts for subcontract opportunities; limit prime contractor profit on subcontracts to actual work performed; and require breakout of components and large segments of weapon systems from prime contracts into open competition. Biggest objector to this proposal very likely will be the Defense Department. It may be an interesting battle.

The care and feeding of a missile system

It takes more than pressing a button to send a giant rocket on its way. Actually, almost as many man-hours go into the design and construction of the support equipment as into the missile itself. A leading factor in the reliability of Douglas missile systems is the company's practice of including all the necessary ground handling units, plus detailed procedures for system utilization and crew training. This complete job allows Douglas missiles like THOR, Nike HERCULES, Nike AJAX and others to move quickly from test to operational status and perform with outstanding dependability. Douglas is seeking qualified engineers and scientists for the design of missiles, space systems and their supporting equipment. Some immediate openings are described on the facing page. Please read it carefully.

Alfred J. Carah, Chief Design Engineer, discusses the ground installation requirements for a series of THOR-boosted space probes with Donald W. Douglas, Jr., President of DOUGLAS

SSILE SYSTEMS ■ SPACE SYSTEMS ■ MILITARY AIRCRAFT ■ JETLINERS ■ CARGO TRANSPORTS ■ AIRCOMB ■ GROUND-HANDLING EQUIPMENT

MISCELLANEOUS

$1,000,000—**Giannini Controls Corp.**, Pasadena, for precision free and rate gyroscopes. (Two contracts, one from **Bendix Products Div.**, Mishawaka, Ind., and from **The Martin Co.**)

NAVY

$71,237—**The Aro Equipment Corp.**, Bryan, Ohio, for MD-1 and MD-2 oxygen regulators.

AIR FORCE

$73,360—**Avco Corp.**, Research and Advanced Development Div., for research and development of an advanced design re-entry vehicle nose cone for the *Titan* ICBM.

$4,500,000—**Kearfott Co., Inc.**, Little Falls, N.J., subsidiary of **General Precision Equipment Corp.**, for production of attitude Coordinate Converter Systems and related equipment used to provide the *Bomarc* Interceptor with directional control signals. (Subcontract from **Boeing Airplane Co.**, Pilotless Aircraft Division, Seattle.)

$980,680—**McDonnell Aircraft Corp.**, for design and fabrication of an airframe part made of refractory metals to withstand space travel temperatures.

$500,000—**Coleman Engineering Co.**, Torrance, Calif., for GAM-77 *Hound Dog* engineering, tooling and production of positioning and transportation trailers and associated hardware.

$225,000—**Eitel McCullough, Inc.**, San Carlos, Calif., for transmitting tirode electron tubes.

$78,868—**General Electric Co.**, Utica, N.Y., for study of disturbances in radio reception associated with passage of orbital bodies.

$57,200—**Sonotone Corp.**, Elmsford, N.Y., for various electron tubes.

$50,000—**Leach Corp.**, Compton, Calif., for development of instrumentation system to help probe the earth's upper atmosphere.

$30,075—**Telechrome Mfg. Corp.**, Amityville, N.Y., for telemetering transmitters.

$25,256—**Westinghouse Electric Corp.**, Elmira, N.Y., for electron tubes.

ARMY

$3,989,999—**Kaiser Steel Corp.**, Los Angeles, for construction of 305-foot self-propelled tower for erecting and servicing *Saturn* missiles.

$3,641,280—**H. B. Zachry Co.**, San Antonio, Tex., for range instrumentation facilities, White Sands Missile Range.

$2,512,495—**John H. Sellen Construction Co.**, Seattle, for construction of *Bomarc* facilities at Paine AFB.

$2,496,759—**Donald M. Drake**, Portland, Ore., for construction of *Bomarc* facility at Adams AFB.

$2,456,792—**Montgomery, Ross & Fisher**, Los Angeles, for construction of a *Bomarc* facility at Vandenberg AFB, Calif.

$1,952,873—**Lawless and Alford**, Austin, Tex. for construction of *Nike-Hercules* facilities at Bergstrom AFB.

$1,674,830—**Browning Construction Co.**, San Antonio, Texas, for construction of *Nike-Hercules* facilities at Dyess AFB.

$1,657,000—**George A. Rutherford, Inc.**, Albuquerque, N.M., for construction of a *Nike-Hercules* facility at Walker AFB, Roswell, N.M.

$450,000—**Telecomputing Corporation**, Los Angeles, for the manufacture of nuclear warhead testers.

$198,271—**Sperry Utah Lab. Div., Sperry Rand Corp.**, N.Y., for radar set.

$104,806—**Western Electric Co., Inc.**, N.Y. for electron tubes.

$84,037—**Radioplane, Div. of Northrop Corp.**, Van Nuys, for drone system, low-speed.

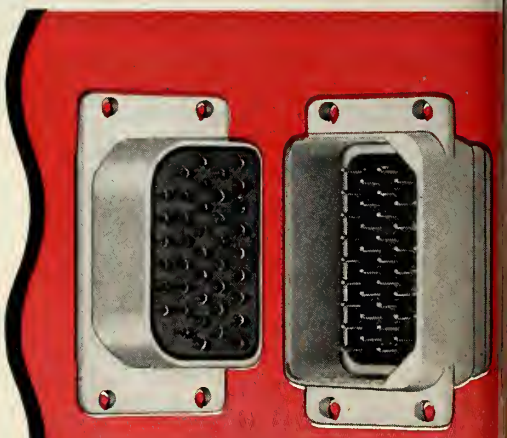
$75,000—**General Electric Co.**, Syracuse, N.Y., for research and development leading to the establishment of designs for solid state reciprocal and non-reciprocal filters, transformers and delay lines and the fabrication samples.

$72,713—**McCullough, Inc.**, San Carlos, Calif., for electron tubes.

$67,095—**Radio Corp. of America, Electron Tube Div.**, Harrison, N.J., for electron tubes.

$55,249—**General Electric Co.**, Schenectady, N.Y., for electron tubes.

BENDIX SR RACK AND PANEL CONNECTOR



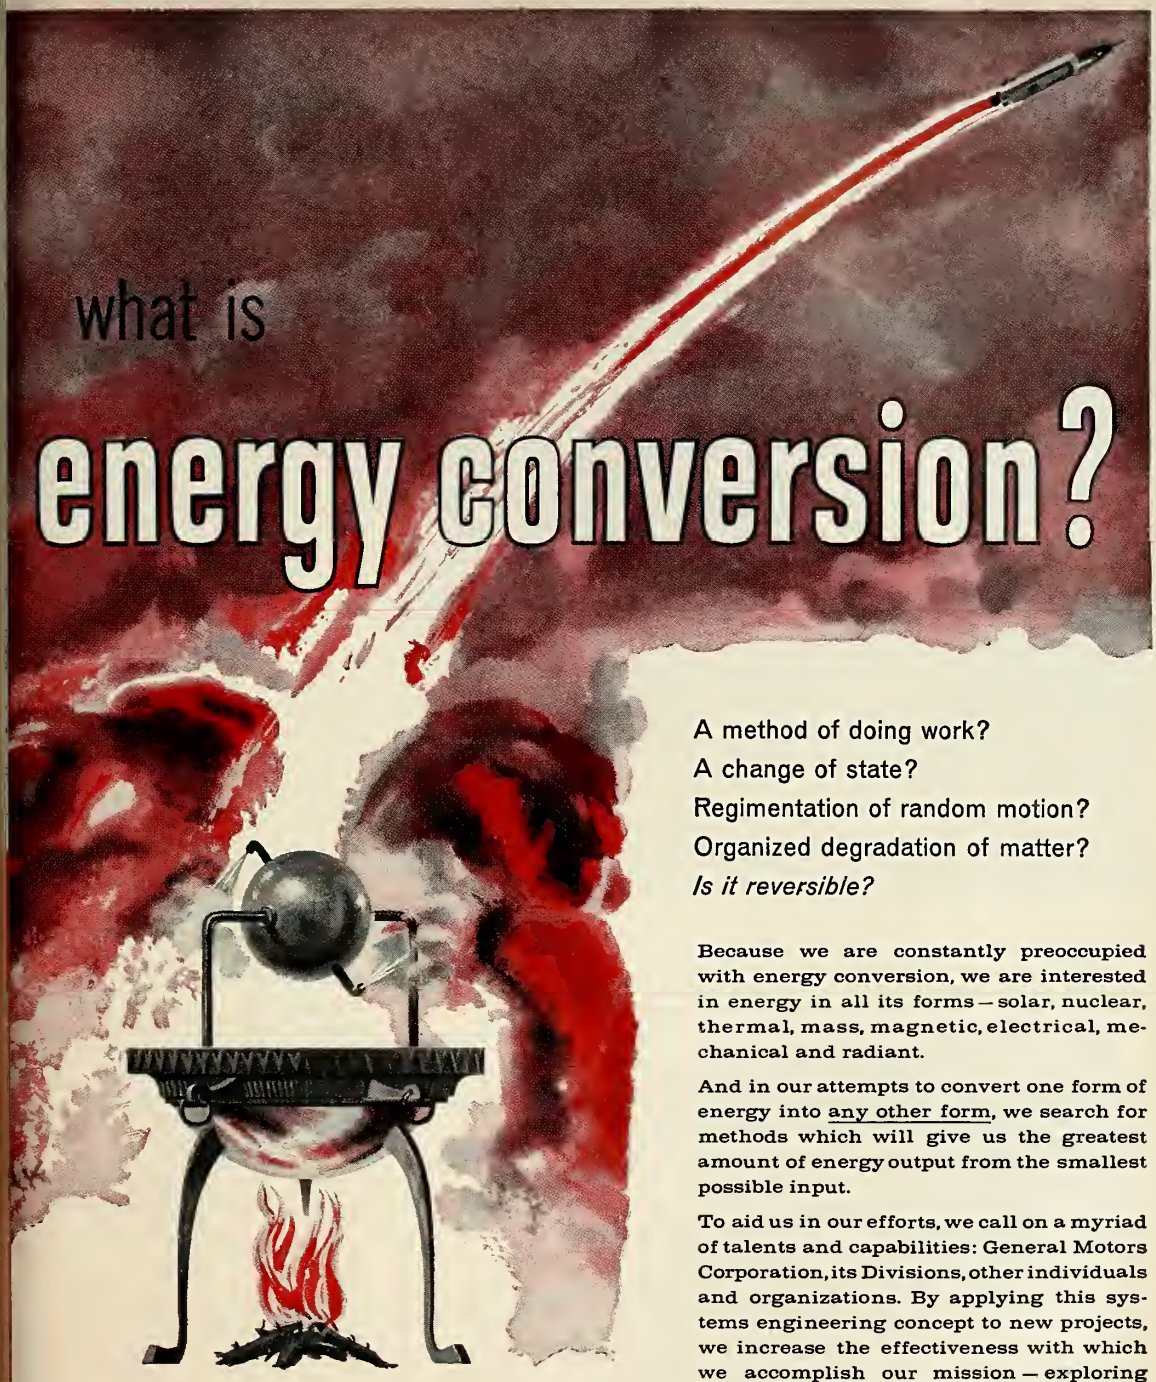
with outstanding resistance to vibration

The Bendix type SR rack and panel electrical connector provides exceptional resistance to vibration. The low engagement force gives it a decided advantage over existing connectors of this type.

Adding to the efficiency of this rack and panel connector is the performance-proven Bendix "clip-type" closed entry socket. Insert patterns are available to mate with existing equipment in the field.

Available in general duty, pressurized or potted types, each with temperature range of −67°F to +257°F.

Here, indeed, is another outstanding Bendix product that should be your first choice in rack and panel connectors.



FEATURES:

Resilient Insert • Solid Shell Construction • Low Engagement Forces • Closed Entry Sockets • Positive Contact Alignment Contacts—heavily gold plated Codmium Plate—clear irridite finish • Easily Pressurized to latest MIL Specifications.

A method of doing work?
A change of state?
Regimentation of random motion?
Organized degradation of matter?
Is it reversible?

Because we are constantly preoccupied with energy conversion, we are interested in energy in all its forms — solar, nuclear, thermal, mass, magnetic, electrical, mechanical and radiant.

And in our attempts to convert one form of energy into any other form, we search for methods which will give us the greatest amount of energy output from the smallest possible input.

To aid us in our efforts, we call on a myriad of talents and capabilities: General Motors Corporation, its Divisions, other individuals and organizations. By applying this systems engineering concept to new projects, we increase the effectiveness with which we accomplish our mission — exploring the needs of advanced propulsion and weapons systems.

Energy conversion is our business

Is the answer to your

HEAT EXCHANGER

problem . . .

THE photographic compilation above is important to you.

It is concrete evidence that among Dunham-Bush Inner-Fin Heat Exchanger equipment you will find the unit which best meets your particular design and performance demands, whether for airborne, ground support, lubricant, missile, computer, or air conditioning system cooling.

Patented Inner-Fin coils make the vital space-saving difference. They reduce a unit's coil size by as much as 60%, yet they maintain the same air and liquid pressure drops through the coil as does a standard finned tube coil which needs much more space.

The answer to your heat transfer problem . . . critical or common . . . is available to you from Dunham-Bush, where product precision and engineering insight combine to satisfy the air conditioning, refrigeration, and heating needs of our growing space-age industry.

AIR CONDITIONING · HEATING · DUNHAM-BUSH · REFRIGERATION · HEAT TRANSFER

E. I. du Pont de Nemours Co. Inc. i planning to give major attention t high-temperature metals at its new re search center now a-building at Balti more . . . At St. Louis, **Monsant Chemical** is starting construction of plant to produce ultra-pure silicon—fo semiconductors . . . Solid-state physics theory of metal binds, the structure o plastics and other research will be ex panded into a new facility being erecte by **Union Carbide Research Institut** near Tarrytown, N.Y. It will be read late next year . . . **Avco** has come u with a small plasma generator for flam spraying ceramics at 15,000°F. Prod uct is similar to devices developed b **General Electric's** Rocket Engine Sec tion and by **Giannini Plasmadyn Corp.,** which developed the first pro duction plasma sprayer.

AF, Navy Cutting Off Boron Fuel Production

Production of boron-type fuel appears to be all but dead. The Ai Force has cancelled the schedule opening next month of a $45 millio plant at Model City, N.Y., wher **Olin Mathieson Chemical Corp.** wa getting ready to produce high energ fuels developed at a cost of $55 millior

The Navy also is ready to shu down its $37 million **Callery Chemica** plant at Muskogee, Okla., the onl other DOD plant concerned with high energy compounds. Earlier this summe the Navy cancelled a boron prograr with **Metal Hydrides,** Beverly, Mas The AF also cancelled the **Gener Electric Co.** J93-5 boron-fueled je engine being developed for the B-7 at a cost of $10 million. B-70, whic may be scratched, will now use cor ventional fuels. (See story on p. 48.)

Actual cents-per-hour wage in creases to be sought jointly by th IAM-UAW in the missile/aircraft ir dustry next year will be decided at "price tag" conference of the tw unions later this year. A 15-cent pe hour hike may be under consideratior

Latest scientific apparatus to b subjected to miniaturization—the mas spectrometer—will make a truly sig nificant transition. A unit being de signed for a 35-inch satellite by **Con solidated Systems Corp.** will occup only one-half cubic foot and weigh 1 pounds. Standard spectrometers use in oil refineries weigh four tons an require an entire small room. Th smallest previous model was a desk type unit weighing 115 pounds. Tw of the new spectrometers will b orbited in a NASA satellite to gain a accurate analysis and measurement o the exosphere between 150 and 60

miles above the earth. Launching is scheduled for 1961.

Army's new satellite-tracking station, atop Madkin Mountain at Redstone Arsenal, went into operation last week. The installation will track ABMA satellites launched under the direction of NASA.

Antennas include two 108 mc colinear arrays, a steerable 20 mc beam yagi, and three simple dipoles. The 108 mc units measure 20 x 20 feet and stand 27 feet high. One is polarized horizontally and the other vertically.

The station also includes receiving and recording equipment, digitizers, automatic teletypewriter to transmit tracking data to the ABMA Computation Laboratory, and an automatic graphic recorder. The antennas, from their 1250-foot mountaintop site, can track satellites anywhere above one-degree elevation.

Two *Minuteman* Silos Being Built at Cape

Launching facilities for **Boeing** *Minuteman*—including two underground silos—will be built at Cape Canaveral during the next nine months under a $5.3 million contract.

The reinforced concrete silos will be approximately 90 feet deep and 26 feet in diameter. Both launching complexes will also include domed blockhouses, instrumentation and launch support buildings, underground checkout and transformer rooms and two 1480-foot service tower tracks.

In addition there will be assembly facilities consisting of one inspection and assembly support building, two missile assembly buildings and two engine receiving and inspection buildings. Specs also call for two engine storage and one missile storage building, some hangar alterations and extensive exterior electrical work. Contractor for the Corps of Engineers is the **George A. Fuller Co.**, Atlanta.

Bendix *Eagle* Team

Contractor lineup for the Navy's long-range air-to-air *Eagle* missile now includes in addition to **Bendix Aviation,** the prime: **Grumman Aircraft Engineering Corp.,** Bethpage, L.I. (major sub for airframe, propulsion system, launching and support equipment); **Sanders Associates,** Nashua, N.H. (seeker); **Litton Industries,** Beverly Hills, Calif. (tactical computer); **Air Arm Division, Westinghouse Corp.,** Baltimore (airborne intercept radar). Bendix's Research Laboratories Division, Detroit, will develop electronic guidance and its Pacific Division, North Hollywood, Calif., will design and produce subsystems and perform missile assembly and tests.

THE GRAND CENTRAL REPORT

Mr. Customer is always the most important visitor to Grand Central Rocket Co.; his first question is most pertinent.

"How is my problem to be handled by your company?"

We have a to-the-point answer:

The day Mr. Customer sends his letter of intent, a full-time Project Manager is assigned.

He reviews the proposal, makes a budget study, sets a work schedule, directs preparation of a contract and assembles a staff.

He reaches into Engineering for the most experience in Mr. Customer's type project. He searches R & D, Manufacturing and Test for precisely the right people for all jobs.

By the time the Customer's contract is here, our Project Manager is in business. He is ready and equipped to be Mr. Grand Central Rocket to Mr. Customer. Throughout the plant, he is respected as Mr. Customer himself.

Thus, our customer deals with a single-point contact who reports at vice president level. Mr. Customer never has to wait for a decision on his project.

Management instructions to the Project Manager are unique: Provide your customer with the *intent of his requirements—within legal limitations!*

We are proud of this position at Grand Central. It is a distinct advantage to our customer when contrasted with a common method of operation—rigid adherence to legal language as the prime requisite while secondarily fulfilling the customer's needs.

Recently we have added new strength to an already strong Project Management staff. Grand Central Rocket's Project Managers are men with the highest technical ability, veteran experience in solid motors and propellants—men of integrity.

We know you will find Grand Central Rocket's streamlined Project Management system a time-saver, a money-saver and an incentive to permanent customer relationships.

John J. Crowley, Vice President
Project Management and Marketing

(If you have the qualifications that a fast-moving space propulsion team needs, contact our Director, Personnel. Openings now for chemists and engineers.)

Engineering and management opportunities in...

RCA SYSTEMS SUPPORT PROJECTS

RCA offers expanding opportunities in Weapon Systems Support projects. This work involves program planning, advanced operations analysis, systems analysis, equipment development and design, and systems integration. Experience is desired in the many areas of systems support—checkout and test equipment, logistics, and training.

Exceptionally fine professional and management positions are available to EE's, ME's, Mathematicians, and Physicists with at least five years of experience.

Salaries are excellent; opportunities for advancement, unlimited. Benefits are among the best in the industry.
Several current Systems Support Project areas are:

Aircraft electronics systems

Military and civil digital communications systems

Missile systems

Space vehicles and space stations

JACKSON

Packard Bell Computer Corp. ha named **Kenneth F Jackson** technic assistant to the d rector. Jackson, wh holds several patent for missile autc pilot devices, form erly was special a sistant to the pres dent of the Waug Engineering Co.

William O. Boschen has been ap pointed to the Board of Directors c Avien, Inc. Boschen also is vice pres dent and general manager of Avien. Be fore joining Avien in 1954, Bosche was eastern regional manager Minnea polis-Honeywell's Aeronautical Divisio and manager of Aircraft Export, Av quipo, Inc., New York.

Douglas Aircraft Co. has appointe three *Nike* Systems project engineers t missile testing activities, **W. J. Binghan** project aerodynamicist on the *Nike He cules*, has been named *Nike* proje engineer (field station testing); **J. L. Cub** chairman of the *Nike Hercules* and *Nik Zeus* test planning and evaluation con mittee, named *Nike* project engineer White Sands missile range; and **L. I Marshall,** test planning coordinator fc the overall *Nike Zeus* field test progran has been appointed *Nike* project enginee at Point Mugu to work out details c future *Nike Zeus* tests on Pacific Missil Range.

SANCTUARY

Cliff Sanctuary, a member of th original radar r search team unde **Sir Robert Watso Watt,** "father c radar," has joine Del Mar Enginee ing Laboratories assistant chief e gineer for ele tronics. Sanctuar served with th British Air Ministry at Bawdsey Researc Station, England, where he participate in electronics development programs an in the initial phases of the British earl warning radar system. Before joining D Mar, he was chief engineer of Decc Radar, Ltd., Toronto, Canada.

FIELDER

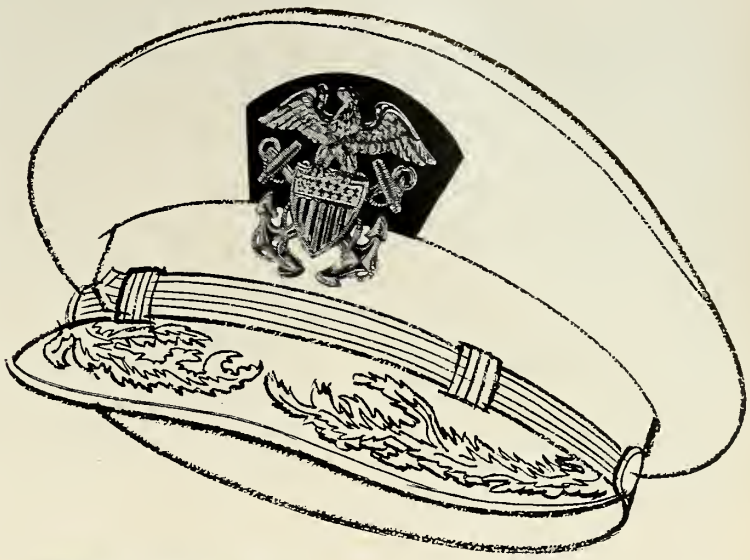
Baldwin-Lima-Hamilton Corp., Phil delphia, has a nounced election **Frederick A. Field** as vice presider and general manag of the corpor tion's Loewy-Hydr press Division, Ne York City. Gener sales manager an assistant gener manager of the d vision since 1955, Fielder succeeds th late **Erwin Loewy.**

Control Data Corp. has announced promotions of the following men who were among the founders of the company when it was established in 1957. **Seymour R. Cray,** formerly associate director of engineering becomes engineering director of the Computer Division. **William R. Keye** has been elected vice president for Research and Engineering. Prior to joining CDC, he held engineering positions with Radio Corp. of America, Airborne Instruments Laboratory, Inc., Engineering Research Associates, and Remington Rand Univac where he was director of Product Design for commercial computer programs.

ROSA

Gilbert N. Rosa has been elected a member of the board of directors of Statham Instruments Inc., Los Angeles manufacturer of transducers. Rosa's elevation to a directorship, according to the company, is part of a long-range expansion plan.

COPLEN



Aerojet-General Corp.'s Liquid Rocket Plant, has announced that **Herman L. Coplen, Jr.,** left the Systems and Control Department which he headed to join the Advanced Research Projects Agency in Washington, D.C. He will specialize in space research and in ballistic missile evaluation. Coplen, 43, joined the company in 1943 in Azusa, was active in the development of liquid fuel assist take off rockets for the Air Force F-84 and the B-47 and pioneered many programs now vital to the Space Age.

Andrew C. Bayle has been elected vice-president—Engineering by the directors of the Waltham Precision Instrument Co. (formerly Waltham Watch). Before joining Waltham Precision Bayle spent several years at Vectron, Inc. where he was chief engineer and assistant to the president.

HURST

Appointment of **William F. Hurst** as Director of Quality Control at the Leach Corp. Compton facilities has been announced. Hurst will be responsible for all quality control activities at the Inet and Special Products Division, including the development and management of a total quality control plan. He was formerly director of Quality Control at Hallamore Electronics Co.

EAGLE

. . . an advanced system program for better professional personnel

As the symbol of our Navy's air-to-air advanced weapon system concept, the Eagle presents a new challenge to senior professional personnel in technical and management fields.

Bendix Aviation Corporation will develop the Eagle long-range missile system. The Bendix Systems Division of Ann Arbor, Michigan with laboratories also in Van Nuys, California holds the prime system management and engineering responsibility.

Specifically, Bendix Systems Division has opportunities for the following personnel in Michigan and California—project supervisors and engineers in:

- **missile guidance and control**
- **countermeasures**
- **weights and aerodynamics**
- **displays and human factors**
- **airborne radar and computers**
- **systems analysis**

Working with top men in these fields at Bendix Systems Division, you will find conditions ideal for personal achievement and pleasant living. If you are interested and qualified, please write Bendix Systems Division, Department K8-17, Ann Arbor, Michigan, or Van Nuys, California.

NEW VOUGHT PROJECTS OFFER CAREER APPEAL TO CREATIVE MEN

Space, ASW, and weapon system work at Vought requires continuous R & D in methods and materials, structures and design. These projects have prompted exploratory work in the following areas:

Structures (Supersonic and Hypersonic)
Heat transfer, thermal stress and deflection analysis, and stress analysis using high-speed computers.

Manufacturing R & D
Welding and brazing of super alloys and exotics; advanced forming and cutting studies; prediction of metal fabricability.

Industrial Engineering
Project estimating, work sampling, line load and balance, and packaging and installation of new procedures.

Antisubmarine Warfare
Studies of detection and classification techniques involving Acoustics, Geomagnetism, Geophysics, Electromagnetics, Electrochemistry, Math.

Engineering Planning
Man-hour and budget forecasting, and project planning and scheduling.

Product Design
Automatic escape devices, atmospherically sound cockpits and advanced instrument displays for space pilot, crew.

Flight Test Instrumentation
R & D in new techniques for electronic gathering and reducing of flight test data.

Aerodynamics
Wind tunnel and model work employing Vought's 3,800-mph high-speed wind tunnel and new "high-temperature" laboratory.

Qualified applicants are invited to write:

J. W. Larson
Ass't Chief Engineer, Administrative Dept. P-15

CHANCE VOUGHT

propulsion engineering . . .

By M/R STAFF

Suppress combustion instability . . .

in solid propellant motors by one of these three methods: Damping, acoustic interference, additives. This is the gist of a paper by E. W. Price, presented at the 9th International Astronautics Congress. Price discusses the three most effective and practicable methods of suppressing instability. "Damping" refers to viscous damping and temperature damping. "Acoustic interference" makes use of geometries that preclude easy excitation of natural modes of the combustion chamber. "Additives" considered by Price are suppressants such as aluminum oxide or carbon which block excitations.

The paper also discusses . . .

the various ways in which combustion instability shows itself and the conditions under which it occurs. Price also discusses the mechanism of combustion instability, the phase relations that permit excitation and methods for detecting instability.

European hydrogen peroxide capacity . . .

expands with the announcement of an addition to **Elfa, Ltd., Electrochemical Works** at Aarau, Switzerland. The new facilities are "Americanized" in that they incorporate designs and techniques used by **Food Machinery and Chemical Corporation's Becco Chemical Division** plants at Buffalo, N.Y., and Vancouver, Wash. It is an electrolytic process. Elfa does not have European missile industry or U.S. missile bases in mind as immediate markets—output will go to the textile, paper, and chemical industries for use as a bleach, plasticizer and chemical process intermediate. Output will be far below the 90%+ H_2O_2 needed for missiles, but the capability will be there if needed.

Synthetic lubricants . . .

for use at high temperatures are among the potential uses that **Union Carbide Corporation** sees for its new *iso*-decanoic acid—a mixture of isomers. Other potential applications are as a plasticizer, defoamer or corrosion inhibitor. Its boiling point (760 mm) is 254°C. It sets to a glass below –60°C. Price right now is 32¢ per pound in tank car lots.

Metallic lithium and derivatives . . .

formerly shipped from **Lithium Corporation's** Minneapolis plant will be shipped from Bessemer City, N.C., beginning in January. Lithium Corp. plans to save $500,000 to $1 million a year by moving everything to its North Carolina facility. The Bessemer City unit, now valued at $7 million, will be expanded; research labs and pilot plants will be added.

Investigating boron?

Boron derivatives are not entirely out of the fuels picture and some firms are either continuing their investigations or starting new ones in the hope of finding a way to salvage work already done. The Oak Ridge National Laboratory makes new types of fundamental studies possible by releasing research quantities of boron containing 92% B^{10} which can be traced through reactions. ORNL also announces availability of special boron compounds made up with B-10.

Russian missile industry chemists . . .

have the same interests and are working on the same projects as are U.S. missile chemists. Examples: T.V. Antipina and E.N. Avdonina are studying the influence of boron fluoride on the catalytic activity of aluminum oxide and alumosilicates. N.A. Slavinskaia, S.A. Kamenetskaia, and S. Ia. Pshezhetskii are studying the effect of ozone on combustion of hydrocarbons.

RELIABILITY

is what determines the success or failure of any weapon system at launch and during flight. Here at the Missile Division of North American Aviation, we are constantly striving to improve this most vital state of the art through analysis and evaluation of environmental criteria, system design analysis, statistical test programs, and other advanced reliability techniques. Engineers and statisticians with a minimum of five years full time related experience in aircraft or missile engineering will find this a most stimulating career in present and future efforts under development.

Project *Tepee* May Cost Less, Outperform BMEWS

WASHINGTON—Project *Tepee*—the Navy's missile warning system—could make the vast multimillion-dollar BMEWS system obsolete.

However, it would not necessarily eliminate the need for *Midas*—the early-warning satellite.

Tepee, now under R&D, is considered capable of detecting the firing of Soviet missiles seconds after launching. That would give about 30 minutes warning time.

BMEWS will be able to detect oncoming ICBM's when they are about 2500 miles away. That will mean about 15 minutes warning.

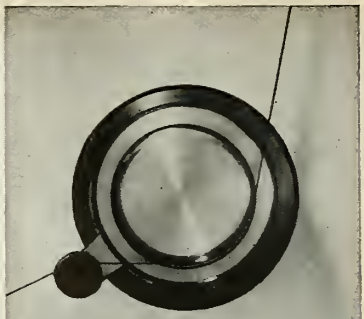
At best, therefore, BMEWS would only provide a back stop for an operational *Tepee*.

RCA's BMEWS is expected to cost more than $1 billion. It probably will be operational in about two years.

The Navy estimates that *Tepee* is comparatively much cheaper and far smaller than BMEWS. It possibly could be operational in less than three years.

Tepee—A development of Dr. William J. Thaler of the Naval Research Laboratory—is based on the use of ionospheric backscatter from high-frequency radar transmitters.

Navy scientists found that backscatter comes not only from the ground but also from plasma clouds resulting from the launching of a missile or nuclear explosions.



• **Success reported**—Thaler and his associates already have detected missile launchings and nuclear explosions over intercontinental ranges by using breadboard equipment.

Moreover, the Navy has strongly indicated that it has detected Soviet missile launchings with *Tepee*. However, it stresses that the entire program is only in the R&D stage.

Thaler says that no breakthroughs are needed to perfect his system. He said the work ahead is mainly in the field of improving the quantity and quality of the information that can be obtained through the use of *Tepee* so that ICBM's can be tracked.

Scientists at Stanford and Yale Universities, **ACF Industries** and several other laboratories have joined in the research work. So far only about $2.7 million has been spent or budgeted for the program.

Tepee does not necessarily affect the attractiveness of **Lockheed's** *Midas* because the use of a satellite for early warning also provides a possible launching platform for trying to intercept a missile once it is launched.

AMPEX: turning point for tape

Magnetic recording has reached the point where a better tape, by itself, can significantly improve the performance of your equipment. Anticipating this, Ampex has developed its Instrumentation Tape to assure the highest capability that the state of the art requires.

Precision tape reliability comes principally from the properties of its coating. And Ampex combines oxide preparation and careful coating techniques with the exclusive Ferro-Sheen process to produce the smoothest, most cohesive, most uniform of precision tapes. The result is measurably higher signal-to-noise ratios, and much less tape wear.

This, with its squared-up hysteresis curve, makes Ampex Instrumentation Tape ideal for all recording systems: direct, FM-carrier, PDM, and NRZ-digital.

Ampex Instrumentation Tape is available on hubs, NAB-type or die-cast magnesium - alloy Precision Reels. Widths of ¼", ½" and 1" are standard on either Mylar* or acetate base, in the following lengths, reel diameters, and base thicknesses:

AMPEX STANDARD TAPE LENGTHS (feet)

REEL DIAMETER	BASE THICKNESS (mils) 1.0	1.5
7"	1800	1250
10½"	3600	2500
14"	7200	5000

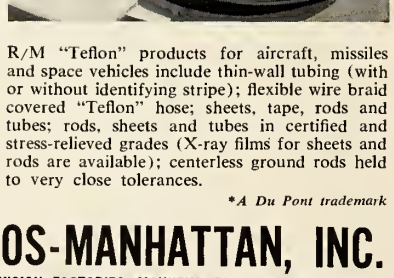
If the job calls for TEFLON* use R/M and be sure!



Minimize the risk of failure of a "Teflon" part or component at a critical point by getting it from Raybestos-Manhattan.

R/M has been in the forefront of "Teflon" development from the beginning. Our engineers *know* "Teflon" . . . its unique characteristics, its vast potentialities, how it can best serve the needs of a particular industry. Our production men have the know-how and complete plant facilities to follow through. You specify it; they fabricate it.

We understand the complexities of your problems—friction, extremes of temperature, the corrosive action of exotic fuels, etc.—and will give you all possible aid in designing, molding or machining the R/M parts or components you need. Make R/M your headquarters for all the "Teflon" products you need. Call upon your nearest R/M district office for the cooperation you require—or contact us direct.

R/M "Teflon" products for aircraft, missiles and space vehicles include thin-wall tubing (with or without identifying stripe); flexible wire braid covered "Teflon" hose; sheets, tape, rods and tubes; rods, sheets and tubes in certified and stress-relieved grades (X-ray films for sheets and rods are available); centerless ground rods held to very close tolerances.

Explorer VI Gives NASA New Tracking Capability

WASHINGTON—The successful c eration of *Explorer VI*'s 8000 sol celled power system gives NASA t capability of tracking deep space prob over 50 million-mile distances.

A fall launching of *Atlas Able* is now scheduled as the first attem to utilize the Space Technology Labor tories' power unit on a deep space m sion.

Early data established *Explorer V* 142 lb. payload's apogee to be 26,4 statute miles, and its perigee 156 s tute miles. The period of orbit is hrs., 46 min., during which the satell so far has travelled a total of 91,1 miles. The orbit's angle of inclinati

is 47° and the lifetime of the orbit now predicted to be much more th one year.

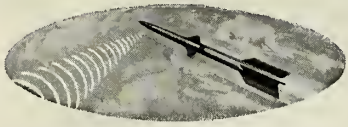
Boosting *Explorer IV* into its hig ly elliptical orbit was a three-stage *Th Able III*. A five-pound solid "kic rocket, which would have been utiliz if the perigee had proved insufficie may be used later to sustain the li of the orbit.

The payload, developed under t direction of STL, carried 15 major e periments designed to tell scientis about the environment encounter over the long orbit, and to test prop gation techniques over long distanc in space. Of particular interest was 2½ lb. scanning device designed relay a crude picture of the earth cloud cover.

Companies contributing researc and hardware to the *Explorer VI* e periment, as listed by STL, included t **Atlantic Research Corp., Engineer Magnetics, Gilfillan Bros., Hallamo Electronics Co., Hoffman Electroni Inc., Motorola Inc., Radiation In Rantec Inc., Space Electronics Cor Stanford University, University of Ch cago, and the University of Minneso**

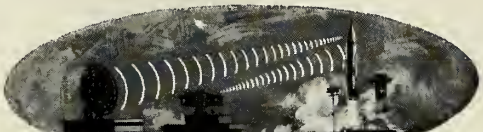
WESTERN GEAR CAN SUPPLY THE SOLUTIONS

PRECISION PRODUCTS DIVISION



To insure the reliability of the missile, its positioning must be accurately and cautiously handled. No matter what mode of transportation, truck, rail, air or water, there are Western Gear precision drives and related equipment engaged in the touchy and delicate task of handling the mighty "birds." Moreover, Western Gear's extensive experience and facilities enable the company to effectively handle your system requirements.

For complete information on our capabilities and facilities, write on your letterhead for Bulletin 5900.



WESTERN GEAR CORPORATION
Precision Products Division, P.O. Box 192, Lynwood, California

5921

Interested in Systems Engineering?

There are systems

...and systems

...and TOTAL systems in which the big bird and support equipment may rank only as a component.

This difference between systems can make a big difference in your career

IF YOU ARE QUALIFIED and interested in contributing to programs of "total" scope, it will be of value to you to investigate current opportunities with General Electric's DEFENSE SYSTEMS DEPT., whose work lies primarily in providing *total* solutions to large scale defense problems of the next 5, 10 and 20 years.

The work here lies almost entirely in the areas of systems engineering and systems management.

Inquire about these positions:

Guidance Equation Engineers
Systems Logistics Engineers
Electronic Systems Management Engineers
Operations Analysis Engineers
Systems Program Engineers
Data Processing Engineers
Systems Test Evaluation Engineers
Engineering Psychologists
Radar Equipment Engineers
Weapons Analysis Engineers
Weapons Systems Integration Engineers
Engineering Writers

Forward your confidential resume at an early date.

Whereas the growth potential is evident — both for DSD and the engineers who join us — the positions we fill during these early months will carry significant "ground-floor" benefits.

Write fully to Mr. E. A. Smith, Room 8-G.

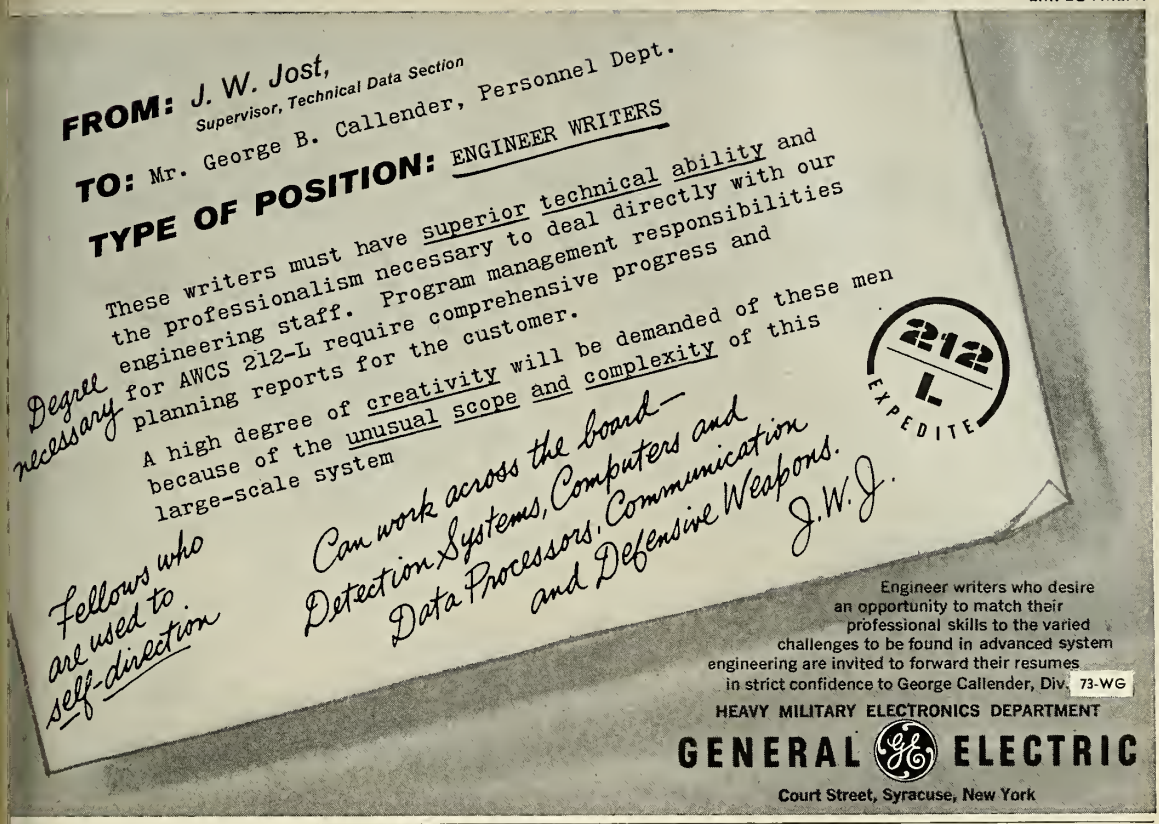
DSD DEFENSE SYSTEMS DEPARTMENT
A Department of the Defense Electronics Division

GENERAL ELECTRIC

300 South Geddes Street, Syracuse, N. Y.

Pentagon Calls Halt to HE Boron Fuels Program

WASHINGTON—Research and deve opment work will be continued i high-energy boron type fuels despi a decision by the Defense Departme to abandon plans for quantity produ tion. However, indications are th this work will be dropped when cu rent contracts run out.



The Air Force has research an development contracts which are co tinuing with **Olin-Mathieson Chemic Corp., Callery Chemical Corp.; AF Corp.,** a corporation owned by **Ame ican Potash Company; Food Machi ery & Chemical Corp.** and **Nation Distillers;** and **Aerojet-Stauffer Chen ical Co.**

The difficulty with the fuel, a cording to informed sources, is that is literally too hot and too expensiv to handle. Original plans called f using it first in aircraft and later i ballistic missiles. As matters no stand, improvements in hydrocarbo fuels—and in chemical fuels producir a higher energy which are less crank to handle—have resulted in by-passir boron—at least for the time being.

As a result, the Air Force will n permit Olin-Mathieson to open i newly completed Model City, N.Y plant which cost about $45 millio Similarly, the Navy will not allow th almost-completed Callery Chemic plant in Muskogee, Okla., to ope The Callery plant cost the Navy f land, plant and equipment abo $35,355;000. Since 1955, the Air For has spent about about $55 million develop boron-type fuels. The Nav estimates its costs for research and d velopment, which started in 1952, about $122 million. The Navy's figur include plant and equipment. How th AF and Navy plants will be use hasn't been decided.

• **Changing Signals**—Pentagon o ficials are using the boron story illustrate the current difficulty in pr viding firm research programs. Abo eight months ago, President Eisenhow in a message to Congress cited th boron high-energy fuel program as major importance. He said the pr gram had a top national priority. No at least for the foreseeable futur there will be no quantity production the fuel.

The big question is why more tha $200 million was spent before the d cision came to write production o Answers may finally be forthcomi when a report now being prepared b **Arthur D. Little Company** for th Secretary of Defense is made publ in mid-September.

The Benevolent Tyranny of Congress

There must be a moral involved in the recent bill passed by both houses of Congress, a bill which requires Congressional authorization *by program* for procurement of missiles, rockets and aircraft. The moral is a little elusive but it probably concerns itself with the fact that Congress in its own way exercises a benevolent tyranny over the Army, Navy and Air Force. Congress giveth and Congress taketh away. And when an indulgent tyrant is goaded to exasperation his benevolence more often than not turns a little sour in hunting a remedy.

The Armed Services are still shuddering over the one-vote margin which defeated a nonsensical bill that would have prohibited any retired officer from being employed by a defense industry. What legislation will eventually be enacted to cover some fairly loose military-industry practices in that area is still in doubt.

But on the missiles, rockets and aircraft front the military is now faced with a vertical financial envelopment which is going to make previous budget troubles—by comparison—seem like capturing Piccadilly Circus on a sunny Sunday afternoon.

For years the Armed Services Committees of both houses have been complaining about the reprograming activities of the services. In so many words, this reprograming means getting money for one thing and spending it for another. There are, of course, restrictions. The Army cannot, for instance, take money for tactical missiles and spend it on reconnaissance aircraft. But they can take the money appropriated for one tactical missile and spend it on another. Just as the Air Force or the Navy can, for example, cut back one program and extend another—within the same category, say missiles or aircraft. Money cannot be shifted out of Research and Development—but it can be moved all over the lot within R&D.

Now by the insidious and dangerous practice of enacting a rider to the Military Construction bill—dangerous because it is almost always done in haste and without proper consideration—Congress has enacted a measure designed to prevent such shifting by requiring a program presentation of missiles, rockets and aircraft production and procurement each year.

How will this work out? Under almost any arrangement it seems certain to double the time spent by the military and defense officials who defend the budget annually before the Congress.

Heretofore the Department of Defense has appeared before two committees in defense of its budget—the Appropriations Committees of the House and the Senate. Now DOD and the Services must first appear before the Armed Service Committees of each house, get an approved program and then, in effect, take this program to the two Appropriations Committees to get the money.

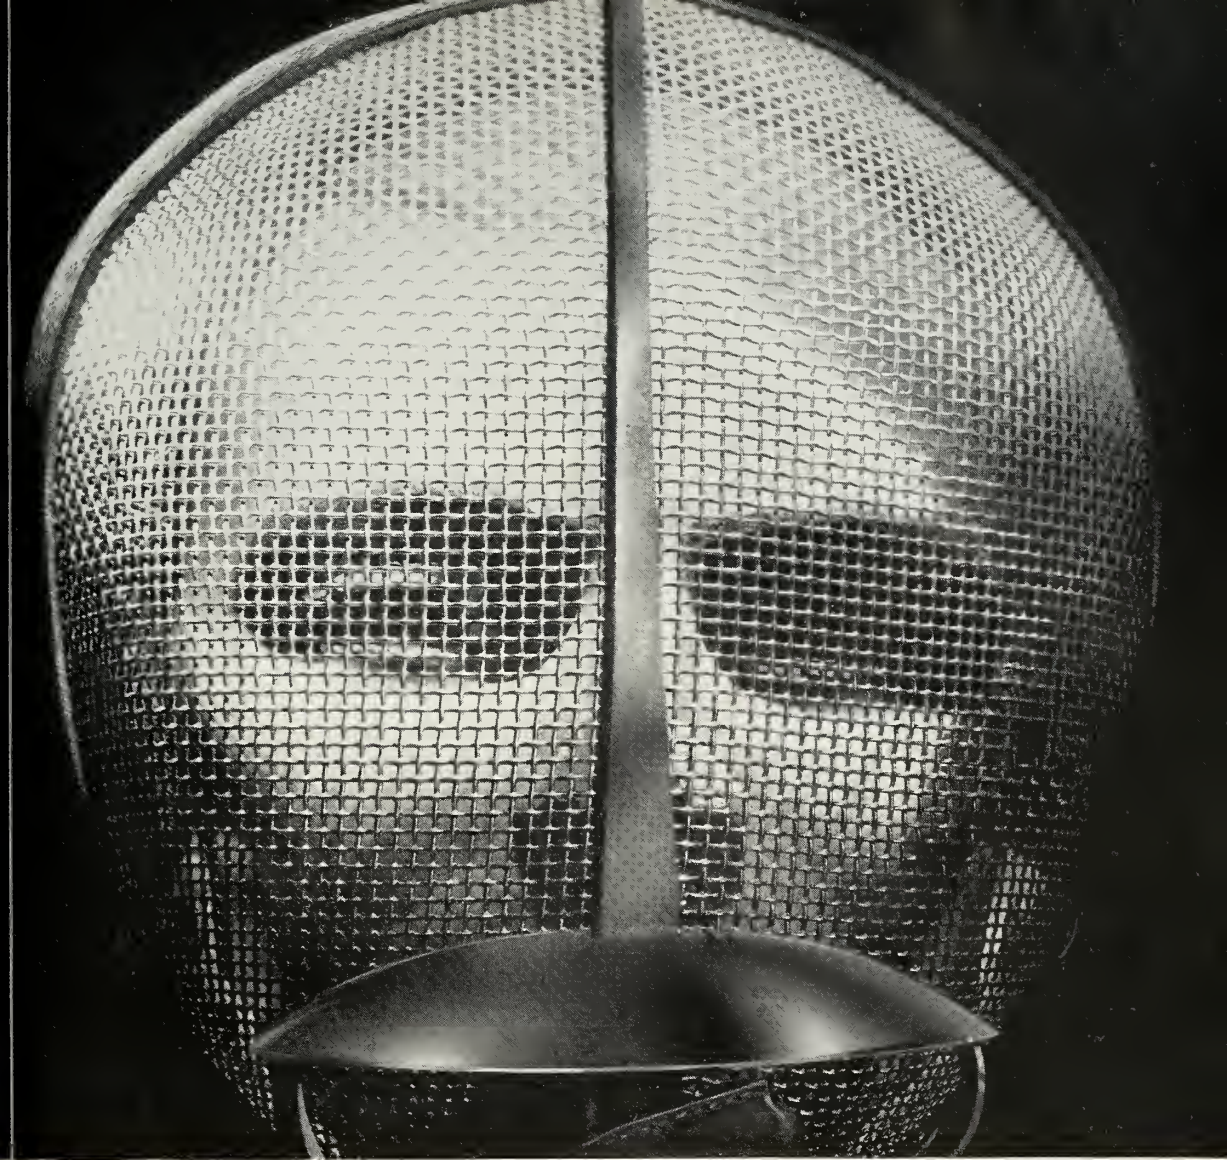
This procedure has long been required for the military construction program because military construction takes place in some congressman's district, an event near and dear to his heart. Congress imposed the same restriction on the National Aeronautics and Space Administration. Each of these, however, involves a much smaller program with infinitely less detail than the multibillion-dollar missiles, rockets and aircraft program with all its complexities.

The exact procedures have not been spelled out and probably will not be until after December 31 when the Army, Navy and Air Force have been directed to tell the House and Senate Armed Service Committees what their programs are and how much each will cost. It is likely also that the actual effect of the new law will not be felt until the 1962 budget. Then the Pentagon will be faced with these difficulties, among others:

The sending up of a budget asking for a specific number of missile, rocket and aircraft wings, groups, squadrons, companies or perhaps flotillas, for a given period. How detailed this must be—no one knows for sure.

The problem of modernization and spares, since they require long lead time.

The fact that the President's budget would then cover only that part of the program to be financed that one year.



The problem of timing, because the program must be authorized before money can be appropriated; otherwise the money will be eliminated as "out of order," as it recently was in the NASA program.

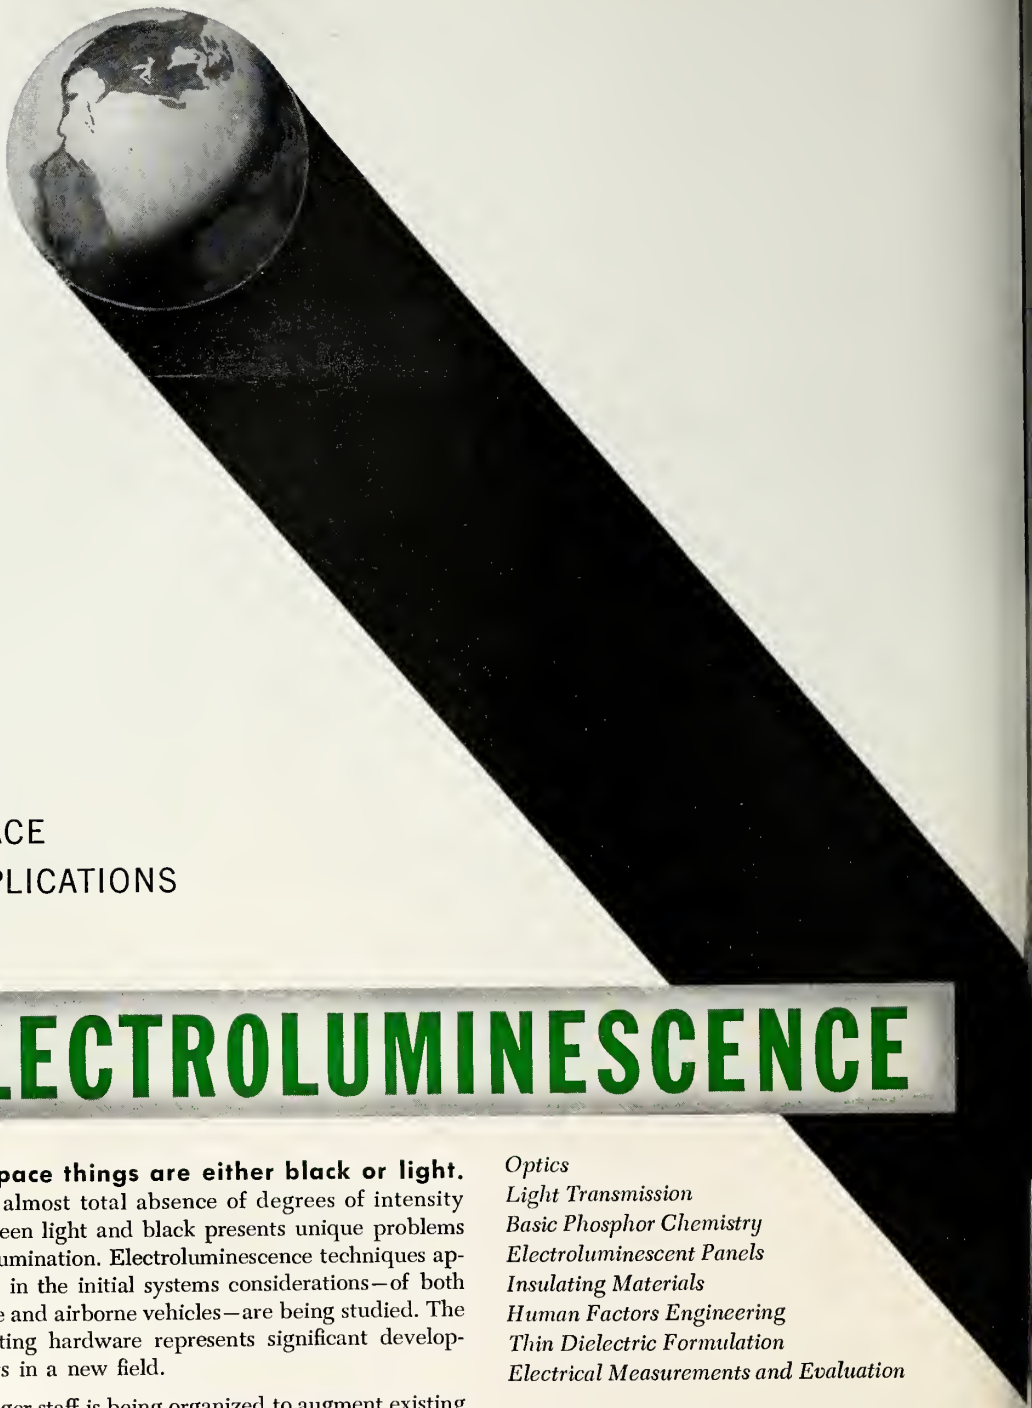
Applying pressure to get the authorization bill out before the end of the fiscal year—because otherwise the continuing resolutions which allow the Pentagon to continue to operate might not be legal without the authorization.

Trying to figure what changes in budget format will be necessary because the rider covers only production and procurement—not development. However, development testing is now included in P & P funding.

What is to be gained from all this? It's a little like the moral involved—somewhat unclear. Certainly it adds time and another complexity to an already unbelievably drawn-out and complex missile, rockets and aircraft procurement and production program.

CLARKE NEWLON

En Garde!



Melpar is an arsenal of technology supplying vital electronic elements linked to the nation's alert, en garde defense posture. Advancing the state of the electronic art is our mission — involving original conception, design, expedited production, and logistics support. Melpar equipment is created and produced for world-wide governmental, industrial and space application.

MELPAR INC

SPACE
APPLICATIONS
OF

ELECTROLUMINESCENCE

In space things are either black or light. This almost total absence of degrees of intensity between light and black presents unique problems in illumination. Electroluminescence techniques applied in the initial systems considerations—of both space and airborne vehicles—are being studied. The resulting hardware represents significant developments in a new field.

A larger staff is being organized to augment existing personnel and facilities. Senior and junior staff positions are open for scientists and engineers who have experience in the areas listed on the right.

Optics
Light Transmission
Basic Phosphor Chemistry
Electroluminescent Panels
Insulating Materials
Human Factors Engineering
Thin Dielectric Formulation
Electrical Measurements and Evaluation

Graduate scientists and engineers with applicable backgrounds are invited to submit a resume to:

Mr. R. A. Martin, Supervisor
Professional Placement Staff

TEST EQUIPMENT CAPABILITY...from SMI

On flight lines and at missile launching sites...in production plants and depot maintenance centers...wherever speed and precision are vital, SMI test equipment capability meets the need with new levels of utility, repeatability...resolution...accuracy.

The SMI line of test equipment ranges from small, portable units that test single functions to console models that test complex airborne and missile electro-mechanical and electronic systems. Included in the line are pressure generation devices capable of generating static, differential and total pressures to simulate conditions from 1000 feet below sea level to 80,000 feet at speeds to Mach 5.

For example, SMI's TS 539 Air Data Computer Test Set is used for checking out elements of the Hughes Aircraft Company MA-1 aircraft and weapon control system. The TS 539 provides both electrical and pneumatic signals to the computer under test, achieving extremely high accuracy by means of electronically controlled force balance sensors. Mach readings are accurate to .7 millimachs and altitude readings within 15 feet at a speed of 1.4 Mach and an altitude of 30,000 feet.

Write today for further information on the TS 539 Air Data Computer Test Set and for details on SMI capability in test equipment.

Engineers: Investigate the opportunities available now at SMI in the fields of aircraft and missile instrument-control systems development.

AN/AMQ-15

. . . concept to reality in one year

Just one year ago, the Air Force Global Weather Reconnaissance Program was only a system concept. Today, the feasibility of this advanced airborne system has been demonstrated at realistic speeds and altitudes.

The Bendix AN/AMQ-15 system includes advanced aircraft sensors for measuring thirteen geophysical parameters along the flight path, and advanced dropsonde and rocketsonde sensors for measuring eight parameters in a vertical profile from sea level to 150,000 feet. Other subsystems are storm radar, cloud top and base radar, air sampling, airborne digital data processing and display, and ground data handling.

For flight demonstrations up to altitudes of 45,000 feet, the Boeing Airplane Company has installed AN/AMQ-15 subsystems in their prototype 707 jet transport. In addition, Bendix has conducted firing of rocket test vehicles at Holloman Air Force Bas

In reporting this achievement of a major syste design and implementation, Bendix is very proud c the contributions of its own divisions, and is mo appreciative of the cooperative teamwork provided b the Air Force, Boeing, and other subcontractors. Th result is a flexible and modular system which can b used in various sized packages for all types of aircra ranging from strategic bombers to interceptors, an for civilian transport aircraft.

The AN/AMQ-15 is typical of the hard-hitting pr grams being carried out by Bendix Systems. Better e gineers and scientists interested in pioneering syste of the future are invited to join this growing tea

IN THE PENTAGON

Space mice . . .
may go into orbit again next month. ARPA and Air Force scientists probably will try to recover mice from an orbiting *Discoverer* satellite around the middle of September. Or they may put a camera in it.

• • •

Development of *Sentry* . . .
the U.S. reconnaissance satellite, is a lot closer than some have thought. The clue: *Discoverer V* achieved stabilization in a desired position this month while in orbit—the second time this has been achieved in the *Discoverer* series. *Sentry* must be stabilized to operate.

• • •

The real story . . .
of the Red missile-sub threat is this: The Russians have not only beat the United States in development of submarines capable of firing missiles while submerged. They also have built a sizeable fleet of the big Z Class missile-subs that cruise within striking distance of U.S. shores. (M/R Aug. 10) Adm. Arleigh Burke, Chief of Naval Operations, gave out only a watered-down account of the threat at his recent news conference.

• • •

First powered flight . . .
of North America's *X-15* rocket plane is expected by about the end of the month. Glide tests of the early rocket craft are reported to have been perfect.

• • •

Underwater missile bases . . .
an idea often heard discussed, is considered impractical by top Navy research experts. They contend *Polaris* submarines are easier to build and will do a better job. However, the idea continues to intrigue some military officials.

ON CAPITOL HILL

The back door fight . . .
between the House Space Committee and the House Armed Services Committee over jurisdiction is far from over. Rep. Carl Vinson, powerful chairman of the Armed Services Committee, warned the Space Committee privately to keep hands off purely military matters. But the Space Committee apparently feels "purely military" is hard to define.

• • •

The boron fuel inquiry . . .
now planned by the Space Committee is the latest example. The committee plans to investigate the recent cancellation of boron exotic fuel contracts—specifically as it affects NASA. The investigation may come within the next few weeks.

• • •

Despite all the noise . . .
don't expect any action soon on congressional demands for much more subcontracting of the defense program. The water is still much too muddy with proposals. But something may come of it all next year.

• • •

Watch for a move . . .
in Congress next year to throw open to public scrutiny U.S. missile aid to NATO and other U.S. allies. The move can be expected to come in the form of a tough new freedom-of-information provision far tougher than the one now moving through Congress.

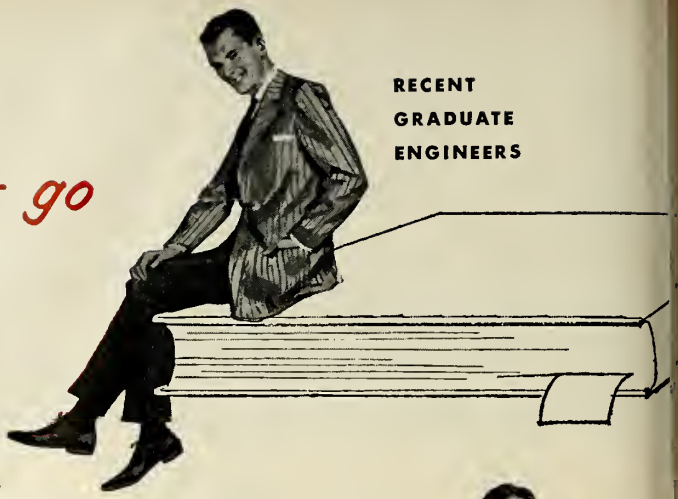
AT NASA

Attempt to . . .
recover the *Discoverer* payload with sky hooks by the Air Force last week was to test the feasibility of the operation for NASA's Project *Mercury*. NASA biomedical scientists are worried that the astronaut might be injured as a result of a water impact or water seepage.

• • •

Sputnik's *III*'s life . . .
is much longer than was originally calculated. It was originally expected to die Aug. 15 after 15 months in orbit, but the Smithsonian Astrophysics Laboratory in Cambridge now gives its death date as December 3. The Russian satellite's apogee has shortened over the last 15 months from 1167 miles to 720 miles, its perigee from 135 miles to 128 miles, and its period from 106 minutes to 98.09 minutes.

AROUND TOWN



Some of the reports . . .
being passed as "the latest" in the nation's capitol:

. . . A whole series of interservice missile/space fights are brewing—some far bitterer than the fight over *Nike-Hercules* and *Bomarc*.

. . . Civil defense against missile attack may become a major campaign issue next year.

. . . There is pressure for toughening with sizeable deployment of missiles the small nations of Southeast Asia—the underbelly of the Far East.

How far can an engineer go at AC?

RECENT GRADUATE ENGINEERS

Free education for the space age

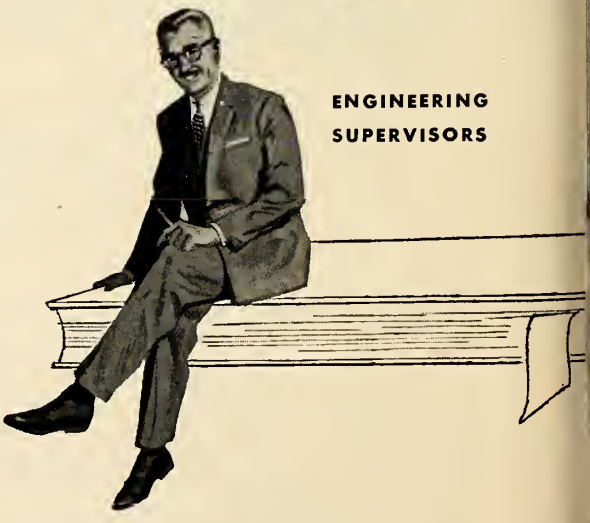
Three levels af special advanced training that can help yau prepare far pramatian and enhance yaur prafessianal status. That's what yau'll find when yau go to wark in AC's instrumentatian business.

Program A—far recent graduate engineers—gives yau a salid faundatian in the theary and application af inertial guidance systems and servamechanisms.

Program B—for experienced engineers—consists of upgrading studies in inertial guidance, servamechanisms, enviranmental prablems, engineering math and physics, plus advanced state-af-the-art caurses.

Program C—far all engineering supervisors—invalves management training develaped by a team af AC executives and University of Chicaga industrial relatians experts.

Camparison will prove these are the finest "in house" pragrams available anywhere. And they are educatianal "extras," far AC affers them in additian to their educatianal assistance pragrams far men who wish to study for advanced degrees in nearby universities.



EXPERIENCED ENGINEERS

You may be eligible for training . . .

if yau are a graduate engineer in the electranics, electrical ar mechanical fields, or if yau have an advanced degree in mathematics ar physics. Yau'll study while yau work on the renawned AChiever inertial guidance system or a wide variety af ather electramechanical, aptical and infra-red devices.

For mare infarmation, write the Director of Scientific and Prafessianal Emplayment: Mr. Rabert Allen, Oak Creek Plant, Dept. H, Box 746, South Milwaukee, Wisconsin.

CHECK YOUR PULSE, SIR?

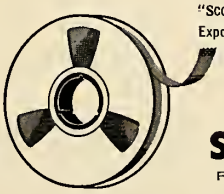
"SCOTCH" BRAND High Resolution Tapes deliver a sharper pulse—with fewer dropouts!

In instrumentation, as in life, it's often the pulse-count that counts. So what if your recording impulses are as square as a bar-graph? If your tape only records camel-backed humps, where are you? Probably about due for a change—to "SCOTCH" BRAND High Resolution Tapes.

Your equipment is somewhat like the proverbial sweater—no matter how advanced, you can only get out of it what you put in. And that calls for "SCOTCH" BRAND High Resolution Tapes—made to deliver improved resolution as pulse density climbs and effective frequencies soar upward to stratospheric heights.

Like so many other advances in tape technology, this superior resolution is a product of 3M research. For one thing, "SCOTCH" BRAND high potency oxides give coatings a higher magnetic retentivity—about a third more than standard. And since the shorter wave lengths of high frequencies are recorded by the surface of the coating, a coating of these potent oxides can be thinner and yet provide equal flux line strength. Results? A flexible tape for intimate tape-to-head contact, a cleaner, sharper recorded pulse.

"SCOTCH" BRAND High Resolution Tapes offer these potent coatings on your choice of two tough polyester backings—158 for standard play, 159 for extra-play. And both are designed to line up your square-waves as densely as a close-order drill, so sharp and clean you'll never miss a bit.



In taping high frequencies, the tested uniformity and dropout-free performance of "SCOTCH" BRAND Magnetic Tapes give the added bonus of reliability. The greater the density of information, the more critical the need for defect-free tapes, and here's where experienced "SCOTCH" BRAND Tape technology really tells.

Whatever your application—data acquisition, reduction or control programming—"SCOTCH" BRAND Instrumentation Tapes supply the reliability you need today and continue to anticipate tomorrow's needs with newer, more sensitive tapes.

In addition to "SCOTCH" BRAND High Resolution Tapes 158 and 159, check the others for your application. "SCOTCH" BRAND High Output Tape 128 offers top output in low frequencies, even in ambient temperature extremes. "SCOTCH" BRAND Sandwich Tapes 188 and 189 end rub-off, build-up, reduce head wear to an absolute minimum, show little wear after 50,000 passes. "SCOTCH" BRAND Instrumentation Tapes 108 and 109 remain the leaders for top performance at low cost.

Where there's no margin for error, there's no tape like "SCOTCH" BRAND Magnetic Tape for instrumentation. For details, write Magnetic Products Div., Dept. MBW-89, 3M Company, St. Paul 6, Minn. or mail the inquiry card. © 1959 3M Co.

"SCOTCH" is a registered trademark of 3M Company, St. Paul 6, Minnesota. Export: 99 Park Avenue, New York, N.Y. In Canada: London, Ontario.

Headed for History... on Schedule

Behind the spectacular fury of a successful rocket or missile launching is the perfect operation of a vital and spectacular valve.

More than likely this important valve is one of the Crane cryogenic globe valves, specially designed for precision control of liquid propellants at temperatures to minus 297 F.

Here again Crane demonstrates some of the reasons for its leadership in valve manufacture. Whether your need is for special valves for missile fuel handling—or valves for a more "down-to-earth" application in the control of water, steam, air or any fluid—Crane can meet your specifications.

Valve guide for the asking

You will find the Crane handbook "Valves for Guided Missile and Rocket Services" very helpful in specifying for liquid fuels, gases, and other fluids used at launching pads, test stations and operating bases. Request your free copy on your business letterhead from your nearest Crane branch or write to address below.

MANUFACTURING

Faulty release mechanism . . .

is attributed to failure of *Titan* ICBM in its fifth flight test Aug. 14 at Cape Canaveral. The bird was held to stand by special clamps for several seconds after ignition while full power was generated. Clamps released prematurely, before umbilical severance. This caused automatic shutdown of main engine, and the bird settled back on the pad.

• • •

Most successful metal . . .

rocket motor cases manufactured so far are rolled and welded and then hydro-spun. Process is used by **Kaiser Metal Products** on *Polaris* cases; by **Pratt & Whitney** on *Minuteman,* and by **Borg-Warner's Ingersoll-Kalamazoo Division** for special test cases. **General Electric's** rocket engine section is using ausforming—hydrospinning during heat treat cycle.

• • •

Materials most used . . .

in these cases are MBMC-1 and **U.S. Steel's** airhardened X-200. Consistent mimimum yield strengths for the cases in the cases in excess of 225,000 psi are reported in each instance, with some test cases running considerably higher.

• • •

This could mean breakthrough . . .

is near in problem of notch sensitivity—the brittle fracture phenomenon which has seriously limited reliability of high-strength, thin-wall cases at strengths in excess of 200,000 psi.

• • •

Fiber metallurgy . . .

is an **Armour Research** project. Hope is for high strength plus permeability in new materials similar to plastics and ceramics. Rocket nozzles are one possible use; another could be for transpiration cooling of re-entry bodies.

PROPULSION

Aluminized powder injections . . .

to speed burning of *Polaris* first-stage solid engine apparently is creating another chain of problems. With faster burning comes high temperatures, particularly in nozzles. Moly nozzles so far are said to be adding a weight penalty in coping with the higher temperature. Other materials—notably steel—may still be used in *Polaris* nozzles. Despite contrary reports circulating in industry, a top Navy official claims "all problems associated with motors in first models have been solved." However, he declines to pinpoint problem areas.

• • •

Charged liquid colloidal . . .

system for low-thrust (2000-3000 I_{sp}) deep space rockets still looks more attractive than the higher-temperature ion electrical propulsion system. **Aerojet-General** is said to have come up with a colloid source which makes problems of focusing, acceleration and neutralization easier to solve. Company believes flyable colloid system is possible in around five years—perhaps less if there is more rapid advancement in development of nuclear-electric source to free the particles from the colloidal solution.

ELECTRONICS

Promising new process . . .

developed by **Stanford Research Institute's** ceramics technology group may raise temperature limits for transistor and diode operation from 400°F to about 1800°F.

• • •

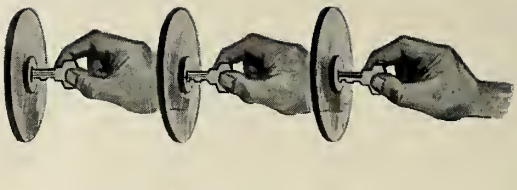
Air Force $10 million . . .

contract to **Page Communications Engineers Inc., Northrop Corp.** subsidiary, for multichannel troposcatter complex will cover 1700 miles, link the United Kingdom, Spain and Morocco.

• • •

Formation of joint . . .

industry-government group to solve problems plaguing telemetry industry is being studied. Purpose would be to coordinate three unrelated groups involved in telemetry—missile ranges, missile makers and instrumentation manufacturers. Joint group would function as a report center and information exchange.



WE HEAR THAT—

Cheaper titanium is coming . . .

Norton Co., Worcester, Mass., has electrolytic process for producing ductile titanium of high purity which may pave the way . . . Copper will be in good supply for 90 days, despite shutdowns. But price of copper is another matter; it's on the way up—fast . . . Plastics information center similar to Battelle Memorial Institute's Defense Metals Information Center, Columbus, will be established at Army's Piccatiney Arsenal . . . **Avco's** Research and Advanced Development Division has delivered an 18,000°F plasma generator to Jet Propulsion Laboratory for NASA re-entry studies.

Reds May Use Lightning as Weapon

Soviet scientists are deeply involved with study of artificial lightning and may have made machines to create anti-missile 'balls of fire'

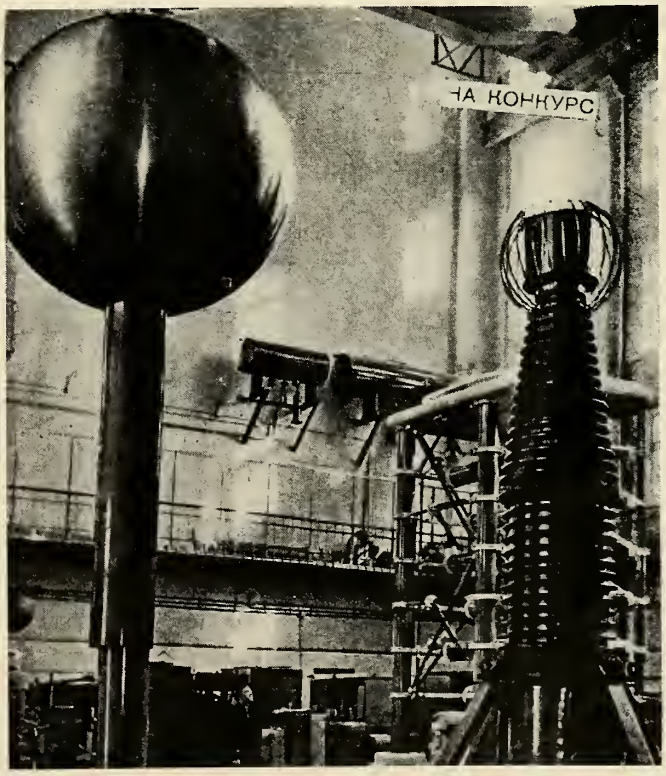
by Donald J. Ritchie*

DETROIT—Lightning balls, among ature's rarest phenomena—described "balls o' fire" in the language of ie mountaineer—may one day be put work as a Soviet weapon of war.

Soviet scientists are using huge- ale laboratory equipment to study tificial lightning. Russian engineers e carrying out programs for de- loping very high voltages and cur- nts. And in the area of basic re- arch, such Soviet physicists as I. M. nyanitov are investigating atmospheric ectrical discharges.

A hint of the military applications ntemplated comes from Physicist eorge I. Babat, head of the Soviet stitute of Energetics. Babat proposes generate balls of lightning in the y high above cities by focusing an tense electromagnetic field with the e of two huge parabolic antennas.

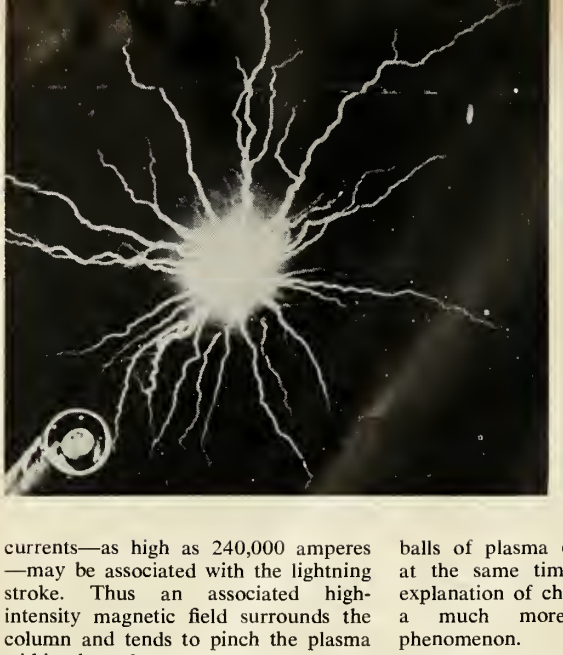
Thus a small artificial star or sun ould be formed. It would be fed from ie ground by electromagnetic energy, it its light output would originate in a uclear fusion process occurring within e ball of lightning—or plasma. The asma ball could be easily moved rough the sky by directing the ground ntennas. The effect of directing it at aircraft or missile can be easily agined.



Such a Soviet weapon is not, of urse, just around the corner. The ork in progress almost certainly is ill in the research phase. But Russian ience is rapidly expanding its under- anding of electrical discharge, ball ghtning and lightning under water. he ability of Soviet engineers and ientists to make very practical use techniques and processes at hand as been demonstrated in the past.

• **Observed data**—Although some uthorities stoutly deny the existence ball lightning, others, such as B. F. J. Schonland, have compiled a great deal of data on characteristics. (*The Flight of Thunderbolts,* Schonland, Oxford University Press, 1950). The present author once observed a lightning ball about four inches in diameter during a violent storm at Kenmore, N.Y.

Lightning balls seem to appear near the end of a severe storm—after the air has been highly ionized and is filled with electromagnetic disturbances caused by genuine lightning. Their diameters range from a few inches to —in rare instances—many feet. They move by rolling or sliding along conductors such as telephone wires, fences and other metallic objects. They travel up and down channels such as chimneys and move both with and against air currents.



The lifetime of a lightning ball may range from a few seconds to many minutes. Its surface temperature can reach 9000°F. When it decays, a great deal of energy is released.

• **Pinching plasma**—One possible method of natural lightning-ball formation is by the "pinching" of a portion of plasma formed in the core of a column of air through which a lightning stroke has passed. Very great

LIGHTNING RESEARCH in the Soviet Union is carried out through the use of such equipment as this, part of the machinery at a high-voltage lab.

Project mathematician, Research Laboratories Div., Bendix Aviation Corp., and close observer of Soviet military science.

BALL OF FIRE under water. Soviet photograph of high-voltage discharge produced at Leningrad Polytechnic Institute shows that end of "projector" is coaxial cable or waveguide, seemingly coroborating idea that lightning ball is combination of electric and eletromagnetic activity. Engineer Lev Alexandrovich Yutkin has charge of work.

currents—as high as 240,000 amperes —may be associated with the lightning stroke. Thus an associated high-intensity magnetic field surrounds the column and tends to pinch the plasma within the column.

An average lightning flash may discharge about 20 coulombs through a length of two kilometers. With the presence of an oscillating field between the ground and the thundercloud, magnetic lines will become unstable and will tend to pinch off a portion of the plasma. Then this is fed by the oscillating electrical field. Many such balls of plasma could be pinched off at the same time. This may be the explanation of chain or bead lightning, a much more frequent natural phenomenon.

• **Equipment produced**—Photographs in Soviet technical journals show equipment alleged to create balls of lightning. Apparently these are formed by a combination of high-voltage discharge and electromagnetic fields. The same sort of research is in progress in the United States, but with rather low voltage and moderate electromagnetic field strengths.

Soviet Academician Peter L Kapitsa believes that the lightning ba is a mass of highly ionized plasma fe continuously from outside by resonanc absorption of intense radio waves. H indicates that artificial lightning bal can be created by a powerful source c sustained radio waves in the decimet range, focused into a small volume c space.

Lev Alexandrovich Yutkin, an e gineer at the Leningrad Polytechn Institute, has made considerable stuc of high-voltage discharge under wate One published photograph of the ph nomenon shows that the end of th "projector" is a coaxial cable or wav guide. This seems to corroborate th idea that the lightning ball is a con bination of electric and electroma netic activity. A recent Soviet relea stated that Yutkin has produced an put to work a discharge of "far great power than lightning."

An obvious application of ba lightning is in igniting controlled the monuclear fusion reactions—avoidin the messy alternative of setting off fission bomb. Thus far, the instabilit of the electric arc discharges used h slowed progress on both sides of th Iron Curtain. Until a method of ign tion is found, it will not be possib to obtain power or propulsion fro fusion reactions. Perhaps the lightnin ball will provide the solution.

IAF's London Meeting May Draw Record Attendance

LONDON—The annual meeting of the International Astronautical Federation at Church House, Westminster, Aug. 31 to Sept. 5 may turn out to be the largest in the Federation's 10-year history.

President Andrew G. Haley of Washington, D.C., estimates that approximately 600 of the world's leading space scientists will attend. The Federation has 3200 members throughout the world.

This year's congress is being organized by the British Interplanetary Society. By maintaining a stricter standard, the various national screening committees have managed to keep the number of technical papers to be presented down to 80; about half of these are from the United States.

• **Soviets uncommunicative**—This figure includes any that might be given by Russian delegates. Despite all the regulations regarding submission of papers, the titles of those from Russia are never known until just before a Congress. This year, the Russians have been unusually reticent and it is not even known whether they will be attending.

Some delegates from beyond the Iron Curtain will be present. These include several representatives from Poland, and one from the Commission on Astronautics of the Czechoslovak Academy of Sciences.

Several hundred members of the American Rocket Society are expected. Included in the American delegation will be seven U.S. Congressmen, members of the House space committee.

The meeting will cover almost every aspect of space exploration. Subjects include space medicine and biophysics, nuclear and electrical propulsion, satellite design, space communications, planetary landings and base operations, astrophysics, rocket postal service, space guidance and navigation, tracking, orbits and trajectories.

Business meetings of the society will deal with such problems as international cooperation in astronautics, documentation, classification schemes and terminology, the need for a permanent headquarters for the IAF, satellite tracking, and the establis ment of an international Academy Astronautics. British delegates to th Congress include G. V. E. Thompso a contributing editor to MISSILES AN ROCKETS, and A. H. S. Candlin.

• **Commonwealth foregathering**— The Congress is being preceded b the British Commonwealth Spaceflig Symposium, August 27-29. Some 1 papers will be presented including or dealing with Britain's place in inte planetary exploration. Some others i clude altitude sounding by solid roc ets, a review of *Blue Streak*, instr mentation, economics of space flight soft moon landings, satellite trackin and recovery, and navigation.

In conjunction with the Congres a Space Law colloquium is to be hel September 4 in the Great Hall, Li coln's Inn, under the chairmanship President Haley.

The Congress will be opened by th U.K. Minister of Supply, Aubre Jones, and a government reception Lancaster House will be held th evening. Other social events include tea party for participants' wives at th House of Lords, an excursion Windsor Castle, receptions and a co cluding banquet at the Dorchester H tel, Park Lane.

Batteries Retain Their Power Role

Survey shows that electrochemical batteries are desirable auxiliary power sources for many missile and satellite uses—sales expected to grow 10-fold

by Charles D. LaFond

WASHINGTON—Electrochemical batries provide a very practical auxilry power source in both missiles and tellites. Fuel cells, nuclear power acks, thermoelectric generators, and e gas-turbine APU have the potential r greater future use, but today the ttery retains its prominence.

According to a **General Electric** pace Vehicle Division spokesman, batries are quite satisfactory and even sirable in missiles as long as the hyraulic and ac electrical systems reire less than 70% of total power—herwise the APU is required.

Batteries won the battle recently for condary power for the *Atlas* ICBM. et cell batteries are used in the *Atlas* drive a **Bendix** ac inverter. After ending something in the area of $20 illion, **Convair-Astronautics** halted exnditure of further funds for **Sundrand's** development of a monopropellt power system for the *Atlas*.

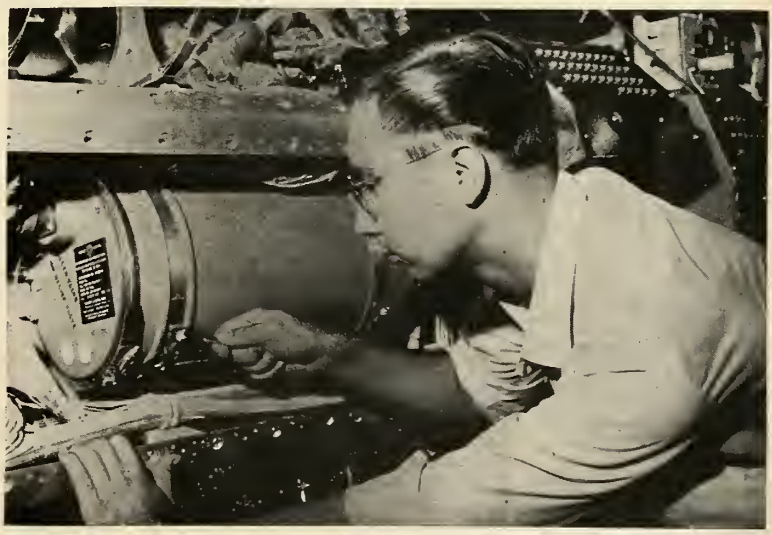
(Sundstrand had come into the *At*s secondary power picture through purchase of the **American Machine Foundary Co.'s** Pacoima division. ne latter had been working on a biopellant system for the *Atlas*. Sundrand changed to a monopropellant ter it took over.)

Convair currently is buying silverlt batteries from **Yardney Electric,** ne **Eagle-Picher Co.,** the **Cook Co.** in enver, and AMF.

• **Business outlook**—Yardney Elecc has indicated that its annual batry sales are in the range of $6 to 7 illion. Of this, 75 to 80% goes to issile, rocket, torpedo and satellite ograms.

Yardney looks forward to a tenld growth of the missile industry by 70 and it expects its battery sales to rallel this growth. Other battery manfacturers share this confidence, at ast for the present.

Auxiliary power for missiles and satellites presents some unique requirements. Requirements for electrical power exist in communications, guidance and control, telemetering, pump motors, ignition, destructive systems and warheads. The accomplishment of this task calls for power ranging from fractions of watts to kilowatts.



In addition to these requirements, an auxiliary power source must meet most or all of the following requirements: it must be lightweight and require little space; it must have good voltage and high rate discharge characteristics; it must be a maintenance-free system and have the ability to be placed into operation on very short notice; it must withstand varying temperatures, low pressure shock, vibration, acceleration, and in some cases, zero gravity.

Depending on the use, primary and secondary batteries meet these needs. Auxiliary power units (APU's) are excellent in view of the weight-and-volume factor. However, they are very expensive and—most important—not yet wholly reliable. Therefore, they are limited in use.

• **Trends**—In general, mercury cells top the list at the present time for satellite use. **P. R. Mallory and Co.** is the principal manufacturer. The mercury cell has a high watt-hour rating but it also has demonstrated a sensitivity to low temperatures. For this reason, the small-size silver-zinc batteries may find increased use in this field.

The trend appears to run toward the standard storage batteries—lead-acid, nickel-cadmium and silver-zinc.

Because of its relatively heavy weight, the lead-acid battery has found few missile applications compared with either the nickel-cadmium or the silver-zinc battery—the most-used power sources for spacecraft. The nickel-cadmium battery gives excellent performance at sub-zero temperatures and stands up very well under maintenance

ELECTRIC Silvercel battery by Yardney is being installed in an Air Force ICBM, to supply main power during flight. It discharges 300 amps at 26 volts for 10 minutes.

electrochemical advantages . . .

abuses. In weight and output, however, the silver-zinc battery is far superior.

Compared to nickel-cadmium, silver-zinc batteries are only a third as heavy; yet their capacity on an equal-weight basis is four times greater.

Because of their low-weight, small volume, high-capacity and reliable-behavior factors, these batteries are considered superior to all others in missile applications.

For the future, some manufacturers feel there may be a move toward use of primaries instead of rechargeable batteries, because primaries offer indefinite shelf life, require no maintenance, and can be used at a moment's notice.

Secondaries, however, have proved their high reliability and—unlike primaries—can be checked before use.

• **Advantages**—The importance of electrochemical battery sources for missiles and space flight can be shown by some of the principal advantages in missile systems.

• They provide direct conversion of chemical energy into electrical energy.

• They are convenient in scaling power systems either up or down.

• Since they have no moving parts, their maintenance is simple and reliability is high.

• The tapping and transmission of power for varying loads is reliable and easy.

• They provide high energy per unit weight.

• They provide high specific power output, particularly in the range of small-size devices.

Primary batteries find extensive missile application because of the short, one-time use involved (excluding ground checkout procedures). The average battery life in a missile varies from four to seven minutes. This short life span requires batteries capable of high drainage, often referred to as "high rate" cells.

Because of the urgent need to save every single pound of weight in missiles, there has been a renewed surge of interest in the development of new and better battery systems.

Secondary batteries (storage batteries) have limited but very useful applications for spacecraft, particularly for use in satellites in conjunction with solar cells. This provides a means of power storage regeneration when the collector area is fully exposed to sunlight and in turn provides power when the satellite is on the dark side of the earth.

• **Silver-zinc**—The most widely used battery for missile applications is the dry-charged silver-zinc system, which has been adapted to auxiliary power applications, because it most nearly fits all of the missile requirements. Also, it can deliver its power output in a very short time. This battery has the highest capacity of all known practical systems. Primary or one-shot batteries are available in automatically or manually activated models; to supply the requirements of a secondary battery, rechargeable models are also available.

Leading silver-zinc battery manufacturers, in order of importance in the missile industry, are Yardney Electric, Frank R. Cook, Eagle-Picher Co., and the Exide Div. of **Electric Storage Battery Co.** The Yardney Silvercel—a silver-zinc battery—has been applied with a record of success in a great many space vehicles, including:

Titan, Polaris, Falcon, Dart, Pioneer, Snark, Goose, Bomarc, Aerobee, X-7, Jupiter, Vanguard, X-17, the *Atlas* satellite and weather satellite.

A *Viking* rocket, powered by a Silvercel battery, was employed several years ago to photograph the earth from an altitude of some 150 miles.

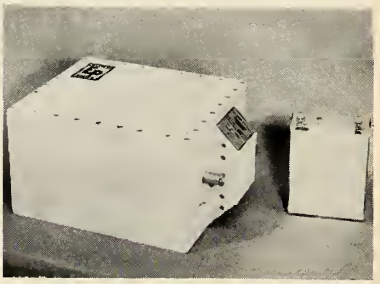
Finally, almost all U.S. Navy electric torpedoes are now using Yardney Silvercels for propulsion and homing devices.

For the design engineer, faced with the increasingly critical limitations of space and weight, the Silvercel battery has shown several strong attributes—a high-rate, rechargeable source of power in a small lightweight package. It can produce the same amount of electrical energy as other battery types, though only 1/5 their volume and 1/6 their weight.

Where high current drains are essential, it can be discharged at rates as high as 30 times the ampere-hour capacity rating. Its voltage is unusually flat, permitting high operational efficiency and dependability. These batteries are available in two rechargeable and two primary types.

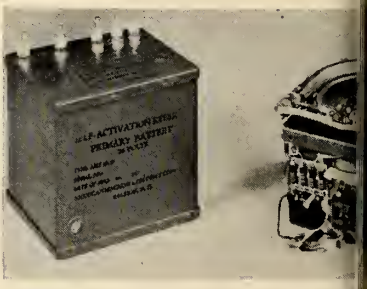
Yardney's newest Silvercel, the PM 200, is capable of an output of 80 watt hrs./lb. The company is currently developing a successor to produce 10 watt-hrs/lb.

Exide Industrial Div. of Electric Storage Battery Co. also produces a whole family of silver-zinc secondary cells. Light weight and small, the units vary from outputs of 7.5 to 200 ampères for one hour at 77°F.



• **Nickel-cadmium** — Nickel-cadmium batteries are most widely known for long life characteristics due to their ability to be trickle charged and overcharged without injury. These qualities make them especially suitable for use as secondary batteries. The low temperature charge and discharge characteristics are quite good and its rugged construction is well suited to resistance of extreme environmental conditions. Although its power output per unit weight and volume is not as high as some other systems, it does provide very dependable long life, secondary battery where weight is not a primary consideration.

Leading manufacturers in the nickel-cad battery field are **Sonotone Corp.**, Eagle-Picher, and **Gulton Industries.** The Yardney Electric Corp. is a newcomer, but, with its new Silcad as a satellite power source, it will be making inroads in this field.



Here the nickel-cadmium system is particularly desirable because high reliability can be achieved by continuous flow of high charging. The units provide good performance over a temperature range of −60° to +160°F and good shelf life in the wet discharged state.

In addition, the nickel-cadmium batteries provide service life from 30 to 2000 charge-discharge cycles.

Another newcomer to this field is **Delco-Remy Div.** of **General Motors Corp.** The company's Electrochemical Research Dept. currently is conducting

MANUALLY activated satellite battery developed by Eagle-Picher Co. has a power-to-weight ratio of 80 watt-hour/lb. including package and hardware.

AMF's Electric Battery Co. has developed this first automatically activated chemically heated Ag-Zn primary battery, less than ½ cu. ft. in total volume.

study program to develop refined sil-r-zinc and nickel-cadmium batteries d new sources of electrical energy.

company spokesman said that new stems under way may provide yields 00% greater than from present bat-ries. The company is known to be orking on a new battery, designated elco-X," but details are still con-lered proprietary and are expected be classified for sometime.

For satellite, telemetering, and re-arch and development applications, anually activated units provide ex-emely high power-to-weight ratios in essentially off-the-shelf item. Each these units is usually modified and ckaged for a particular application.

Eagle-Picher has developed and de-gned manually activated batteries for tellite applications. One such battery, own in photo, has a power-to-weight tio of 80 watt-hours/pound includ-g packaging and other hardware. En-ronmental conditions imposed on any of these types of units include)-g vibration, 60-g shock and 18-g celeration in addition to many other vironment extremes.

• **Solid state**—The Patterson-Moos esearch Division of **Universal Wind-g Co.** has developed a family of solid-ate batteries for subminiaturized sys-ms. Based on the use of a crystalline ectrolyte, conduction is entirely ionic. alled "Dynox," cell configurations are vailable having cell thicknesses of less an 0.005 inch and total power pack zes less than 6 cu. inches. Some units, cording to Patterson-Moos, have op-rational lifetimes in excess of 10 years.

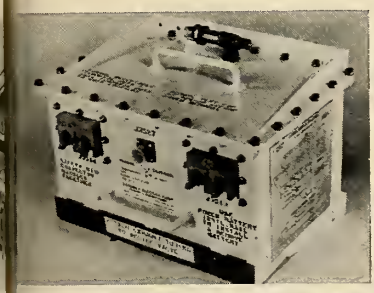
Hermetically sealed, the batteries rovide high shock and vibration re-stance. They can be operated in a mperature range of from —100° to 70°F.

Producing 0.8 volt per cell, single nits can be obtained which will pro-ide up to 950 volts (open circuit) and current of 10^{-3} milliampere for 100 ours at 70°F. Voltage drop is less than 0%.

Dynox batteries have an estimated shelf life of 20 years at from –40° to 70°F (2 years at 130°F).

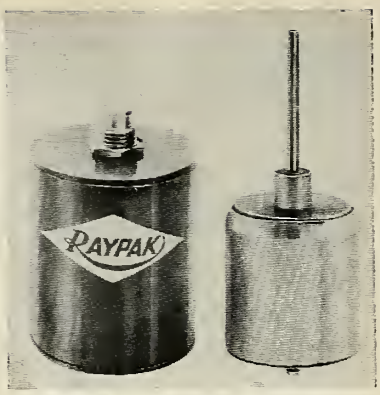
• **Nuclear**—Another Patterson-Moos Research development is a family of nuclear batteries. Weighing 9 grams, the units measure 9/16" x ½" diameter. They can supply currents rated at from 10 to 200 $\mu\mu$amperes with equilibrium voltages from 5000 to 10000 volts at 70°F.

Construction consists essentially of an emitter electrode coated with a radioactive isotope (β-emitter) and separated from a brass collector case by a solid dielectric.



Having a shelf life and use life of 25 years, the units also are independent of adverse physical and chemical conditions, according to Patterson-Moos.

Nuclear power packs—called Raypaks—also are available. Comprised of a PMR nuclear battery, a capacitor, and voltage regulation network, the units are completely encapsulated. These units are provided with voltage ratings of either 375 or 750 volts. They weigh 80 grams and are 1.5" long x 1.25" diameter overall. Particularly designed for trigger power in weapon and ordnance systems, Raypaks can provide a pulse energy source of from 800 to 337,000 ergs.



• **Thermal**—Thermal cells are primary cells or batteries incorporating a solid salt electrolyte which is activated by melting the solid electrolyte to make it conductive. This feature provides excellent unactivated shelf life and a means of operation independent of ambient temperature. Although its capacity is not high when compared to other practical systems, it does possess advantages which suit it to specific power requirements. Currently under development by the Eagle-Picher Co., applications and details of these thermal cells are classified.

• **Water activated**—Water activated batteries, also produced by Eagle-Picher, are units which operate when immersed in, or wet by water of 0 to 4% salinity at 28 to 210°F. They are capable of voltages from 1.5 to 1000 volts at currents of from hundreds of amperes to milliampere ratings with discharge life ranging from a few seconds to two days, and with activation time variations from one second to one-half hour. These broad capabilities are covered, in general, by two similar electrochemical systems: silver chloride-magnesium and cuprous chloride-magnesium batteries.

In general, these batteries are designed for air discharge or submerged discharge. The former are manually activated by soaking in water prior to use, while the latter operate submerged in water. Typical applications for the air-discharged are as power supplies for radiosonde balloons. A principal use for water-submerged batteries is in underwater ordnance.

NLY 55 pounds, this Yardney Elec-ic rechargeable Silvercel battery sup-lies energy for guidance electronic gear nd telemetering in missiles.

TWO MEMBERS of the Patterson-Moos family of nuclear power sources. Left, nuclear power pack; right, nuclear battery. Both have 25-year life.

• **Late report**—As M/R went to press, late information was received indicating the reason for Convair's cancellation of the hot-gas APU programs at Sundstrand and Aerojet-General for *Atlas* and *Titan* ICBM's.

A comparative study of hot-gas vs. battery auxiliary power sources for the *Atlas* was performed recently by the Frank R. Cook Co. The report indicated that in all instances of comparison hardware for missile batteries proved to be of less weight than that required for the hot-gas APU's.

After review by the USAF Ballistic Missile Division and Ballistic Missile Office, the APU program cancellation immediately followed.

Frank R. Cook has stated that his company is providing units for "all eight *Atlas* type batteries, four types for *Polaris*, two for *Minuteman*, and others."

New Process for Synthesizing Crystals

SAN FRANCISCO—A new method of synthesizing nearly perfect ferrite monocrystals from a mixture of ferric oxide and other oxides has been revealed by International Telephone and Telegraph Corp.

Developed by ITT Laboratories, crystals can be grown in quantity by a process described as "flameless fusion." This is a thermo-chemical reaction (2000°F) accomplished with high frequency radio energy.

ITT believes process will open new avenues in solid-state electronic research.

Crystals approximately 1.5" x ¾" diameter were displayed for the first time at the 1959 Western Electronics Show and Convention here at the Cow Palace.

Page's DTC Has Wide Potential

Simple device performs well in NATO scatter stations and is expected to find application in telemetry, especially over long distances

by Charles D. LaFond

WASHINGTON—Sometimes a simple, inexpensive gimmick can be as noteworthy as a more impressive breakthrough—that is, if the gimmick has potentially wide application.

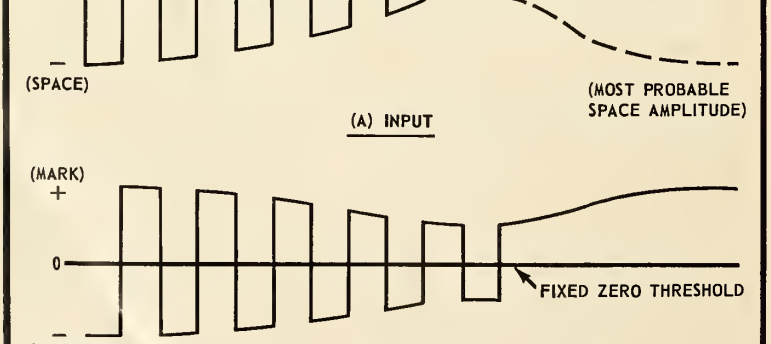
Such a device may be **Page Communications Engineers'** new circuit technique called a "decision threshold computer" (DTC) which enables a frequency-shift-keyed receiver system to use information in mark and space channels independently when fading exists between the mark and space frequencies.

Designed, built and tested in Page's Takoma Park, Md. lab and at its Taylors Island Field Station near Cambridge, Md., the diversity technique has produced a significant performance improvement in high frequency and scatter communication circuits.

Currently employed with marked success in NATO's European scatter stations, the technique will be utilized in the many other scatter links around the world. It should also find use in telemetry, principally for long-distance applications.

DTC is designed to make use of the normally deleterious effects of frequency selective fading. It provides up to a 30-fold reduction in telegraph and binary data transmission error rates. This corresponds to a 16-db improvement.

By using the lack of correlation in mark and space signal fading, it effectively provides additional orders of diversity. For a dual-space diversity system, DTC, according to its developers, will produce an overall advantage of quadruple AM diversity, if the correlation between mark and space signal fading is sufficiently low. This is accomplished by separately storing mark and space amplitude formation and deriving from this optimum threshold level.



• **AM-FM decisions**—In the modulator of a typical FSK syste mark and space usually are rep sented, respectively, by positive a negative output voltages. The decisi threshold voltage is set at zero.

Unfortunately, FSK signals generally assumed to be balanced, the optimum decision process assur that the signal amplitudes and nc levels are the same for the mark space channels. (This is based on optimum decision criterion presen by Middleton and Van Meter, "Mod Statistical Approach Reception in Cc munications Theory," *IRE Professio Group on Information Theory*, S tember 1954).

Under conditions of selective f ing between mark-space frequenc the FSK decision criterion is no lon optimum. Moreover, with a deep f on either frequency a substantial nu ber of errors could result.

Thus another decision criterion needed, for an AM decision on eit mark or space, as appropriate, wo be optimum. Without this, there is provision for changing both the cision criterion and the threshold, performance would be unsatisfactor

The receiver makes an FSK cision between mark and space wh the amplitudes are equal, but ma an AM decision on the stron channel when the other channel fa completely. A function switch on DTC switches between four mo of operation: Bypass, DTC is connected from the circuit for use w Anti-Multipath Equipment (M/R, Ju 22, 1959) or for testing; Normal, D is connected; Mark, receiver makes AM decision on the mark signal or and Space, receiver makes an AM cision on the space signal only. T latter two positions are used in event of interference on either chan

PAGE decision threshold computer's input and output diagrams.

MOVING AHEAD----

"TO PROVIDE FOR THE COMMON DEFENSE"

Only by conceiving today the weapons which will be needed tomorrow; can the free world continue to preserve the peace—or successfully meet an attack.

TIME IS OF THE ESSENCE!

ANOTHER STEP FORWARD

To cope successfully with this urgent and continuing problem, RCA recently extended to a corporate-wide basis the techniques which had been proven successful within its various departments, by creating an *Advanced Military Systems* organization at Princeton, New Jersey. There, in an atmosphere of intellectual freedom, a group of mature scientists and engineers are engaged in the analysis and study of our national defenses—present and future—and how they can be made most effective to meet any future enemy capability.

These studies are conducted at the frontiers of knowledge and encompass such areas as the physical and engineering sciences, military science, economics, and geophysics. Studies have, as an end result, the creation of military systems which will satisfy projected military requirements.

A SPECIAL KIND OF MAN

Members of the technical staff are at the highest creative and intellectual level. They have a degree of maturity which comes only with many years of experience. They generally have held responsible positions in research, advanced development, or systems planning. Most of them have an extensive background in the broad fields of electronics, vehicle dynamics, physics (astro, nuclear, or plasma), or military science (operations research). All are temperamentally suited for performing highly sophisticated, comprehensive analysis and planning of a detailed nature. They are men who enjoy seeing the fruits of their work turn into realities that have an extensive effect on the defenses of the country.

A SPECIAL KIND OF CLIMATE

Each member of the technical staff operates either independently or in a loosely organized group, and is generally free to select his own area of work. The only condition: results must have a direct application to problems of national defense. He has no responsibility for administrative details, although he must be ready to give guidance to program implementation. He can call in any specialists he may need. He has full access to all available information—military, academic and industrial. Specialized research projects and laboratory work can be carried out at his request by other departments of RCA. In a word, he is provided with every opportunity and facility to use his creative and analytical skills to maximum advantage and at the highest level.

A SPECIAL KIND OF ENVIRONMENT

Princeton offers unique civic, cultural and educational advantages along with the convenience of its proximity to New York City. In this pleasant environment, Advanced Military Systems occupies a new, air-conditioned building on the quiet, spacious grounds of RCA's David Sarnoff Research Center. Working in individual, well-furnished offices, staff members find their total environment highly conducive to creative activity.

INQUIRIES ARE INVITED

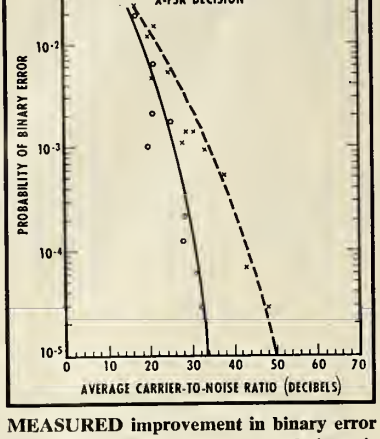
RADIO CORPORATION of AMERICA



remarkable gains in detectability . . .

and for testing.

When the DTC is operated in the Mark position, the receiver in effect becomes an AM receiver operating on the frequency of mark signals only. The space signal is ignored by the decision threshold computer, and the resultant intelligence is translated from unipolar to bipolar keying to actuate the remaining circuitry of the combiner. In this way, disruptive interference occurring on the space frequency can be avoided at the expense of a slight degradation of normal performance. For reception in the Space position, the converse of the above is true.

The British "assessor" (described by Allnat, Jones and Law, "Frequency Diversity in the Reception of Selectively Fading Binary Frequency Modulated Signals," *Proceedings IRE,* Aug. 1956) can be used to automatically change the decision threshold, but its frequency response does not extend to dc. Thus, a decision failure may result with some types of traffic.

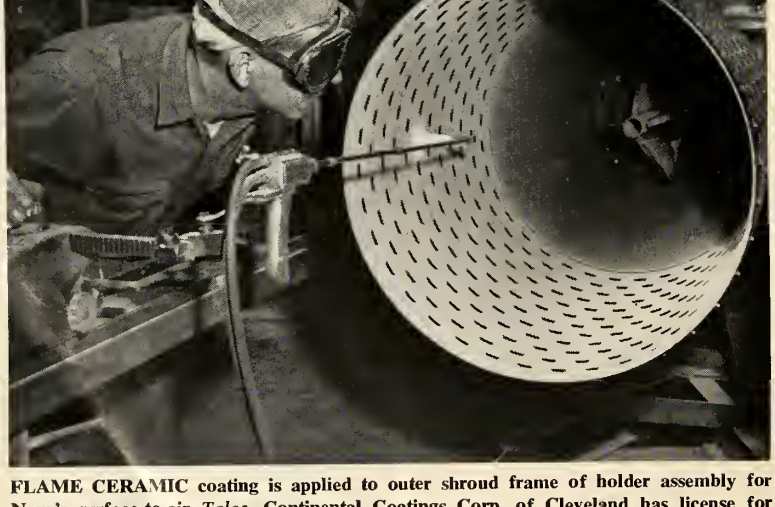
The Page DTC provides automatic adjustment of the decision threshold. Also, if signal polarity remains constant, the decision threshold is returned to zero for the FSK decision.

MEASURED improvement in binary error rate using Page's new DTC technique is shown by comparison of data with contemporary FSK decision method.

• **Performance**—Extended tests of DTC using the facilities of the ionoscatter test link between Round Hill, Mass., and Streator, Ill., showed that the circuitry remarkably improved the detectability of FSK signals. Mr. Ga Boggs, assistant director of researc at Page, has stated that the use of th device, under some conditions, mig recover traffic on scatter circuits th would otherwise be lost. Page eng neers also felt that an operational a vantage was achieved because le critical receiver balance adjustmen were needed than with convention FSK decision techniques.

The experiments by Page have ind cated that using the DTC circuit tec nique with live FSK signals, in th presence of selective fading mak possible a 5- to 20-fold reduction errors over those resulting with co ventional FSK reception using du space diversity. Similar improveme can be obtained with a 3 to 6-db i crease in transmitter power. Whe operating non-diversity with a sing receiver and under comparable cond tions, the error rate was reduced 10 30 fold, corresponding to an improv ment of 10 to 16 db. An example the results obtained in the latter ca with live signals is shown in the grap to illustrate the effectiveness of th technique.

Tiny Resistor Produced by Sputtering Technique



NEW YORK—Microminiaturizatic has moved another step ahead wit **Bell Laboratories'** announcement "sputtered" thin-film resistors. The r sistors, formed from refractory meta such as tantalum and titanium, can b produced on glass or ceramic bases i lines as narrow as one mil. Equivale printed circuits produced by regul methods are more than four times th size of those made by sputtering.

Bell has been researching the spu tering technique for several years. La year it announced the production tantalum capacitors by this method.

Sputtering is an old technique i which ionized gas molecules bombar a cathode, dislodging atoms of met which redeposit on nearby surfaces.

In producing a component by th method, an overall thin film of copp is first sputtered onto the surface the base. Then the desired pattern etched into the copper surface b standard photoetching, leaving the ba substrate exposed. The tantalum—o other refractory metal—is deposite onto the etched copper pattern. Th copper with its overlay of tantalum removed in an etching bath, leavin only the tantalum which was in direc contact with the bare surface. Sinc the masks are extremely thin, fin detail is possible.

Talos Gets Coating

FLAME CERAMIC coating is applied to outer shroud frame of holder assembly for Navy's surface-to-air *Talos*. Continental Coatings Corp. of Cleveland has license for process, developed by Armour Research Foundation. Aluminum oxide coating is applied in powder form to metal combustor. Molten alumina then freezes on metal and adheres by mechanical bond.

Bowmar Leads Precision Gear Field

Firm makes millions in work largely ignored by big missile manufacturers and its head views today's precision miniatures as mere prelude to future

FORT WAYNE, Ind.—Producing iniature gear packages for use in **onvair's** *Atlas* telemetry, **Martin-Or-ndo's** new *Pershing* inertial guidance, nd **North American's** *X-15* spacecraft avigation, the **Bowmar Instrument Co.** rapidly cornering a large portion of ne of the missile industry's youngest nd fastest-growing fields—develop-ient and production of precision, iniature transmissions.

These components have been some-hat ignored in the past by the large anufacturers because of the meager emand for the midget units, and be-ause it was uneconomical to establish ie miniature, high precision tooling equired.

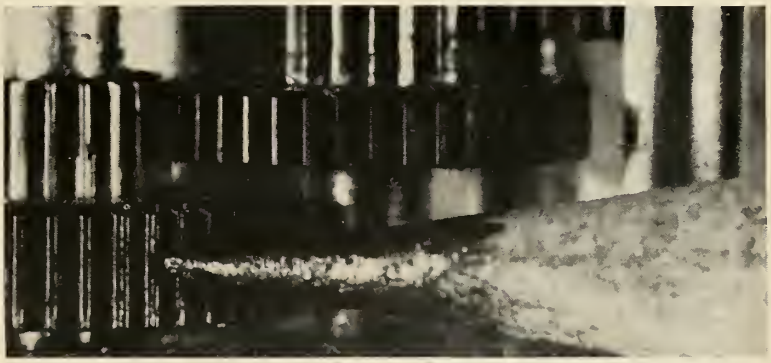
Bowmar is the nation's largest pro-ucer of miniature mechanical com-onents with control of more than alf the market. Although there are andard lines of gearheads and servo-ackages produced in the industry, uch of the work deals with the de-gn and production of custom-devices or air and space navigation and con-ol systems, as well as telemetry, round computers, and atomic engine erve centers.

• **Doubles gross**—In 1956, Bowmar chieved an annual gross of just over 1 million. The annual gross has more an doubled each year since 1956. pproximately 92% of Bowmar's 1958 ales (total over $4 million) were tied military contracts. The remaining % of their business was for com-ercial airliner controls and naviga-on applications. Along with the ever ontinuing need for greater minia-urization for the missile industry, the uture growth area in this field cer-ainly appears to be in this latter evelopmental group.

To build these micro-mechanisms, Bowmar spokesman said that the ompany currently operates on speci-ed tolerances of 0.0002 inch for meas-rements of center shaft diameter, haft center distance, tooth to tooth, tooth width, tooth backlash and out-side diameter.

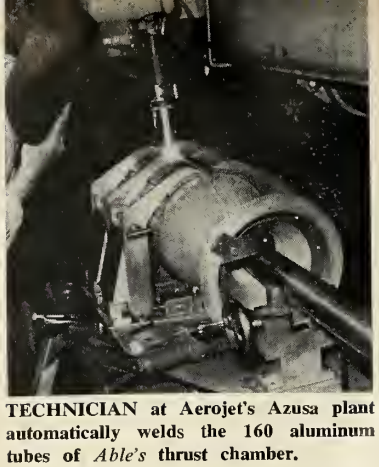
This kind of precision requires ex-tremely tight controls through the entire manufacturing operation. The gears are manufactured on both Swiss and American type precision gear hob-bing machines. The teeth are cut to the accuracy required in one operation and are finished except for minor burr removal which is performed after-wards. To check the exacting toler-ances, a great many precision equip-ments are required, such as gear roll-ing machines that record total com-posite error of the gears to less than 0.00005 inch.

To increase reliability, the tiny parts are ultrasonically cleaned and assembled in a dust-proof chamber. Bowmar maintains a "clean room" that is pressurized, sound proof, and tem-perature controlled at a positive 72°F and controlled 50% relative humidity.



Each month the company assembles an average of 125,000 individual parts, ranging from gears of 0.177" diameter, to pinions of 0.09" diameter and to ball bearing units 0.1" diameter. Fitted together under microscopes, these parts are combined into gearheads, speed re-ducers and servo-packages.

New techniques have permitted the development of ¾-ounce transmissions that can increase torque from a 0.3 inch-ounce input to an output of 540 inch-ounces, using motors of 0.00008 horsepower.



Biggest problem is to keep up with the servo-motor manufacturers, who are currently shrinking motors to these small diameters, and low outputs. Given the job of miniaturizing the size and weight of an inertial-guidance servo-package to meet new specifications for the Army's *Pershing* IRBM, they reduced the unit three times to a final miniaturization of 2½ x 2½ inches and less than 20 ounces in weight.

Grape-sized miniature gearheads are now being produced ranging in speed-reduction ratio up to 3 million to 1 and priced up to $2000 each.

Currently working on a 1" long gearhead that will produce a 6000-to-1 reduction ratio, Bowmar's president Ed White contends that his company and its fellow miniaturists have barely scratched the surface. Before space ve-hicle design can go much further, he believes it will require mechanical pack-ages even more reduced and complex. Compared to future units, Bowmar feels that current devices will seem not only crude but outrageously large.

SCARCELY larger than sharp pencil point, this Bowmar miniature gearhead is used in guided missile control packages and, more commonly, to slow down computer motors.

TECHNICIAN at Aerojet's Azusa plant automatically welds the 160 aluminum tubes of *Able's* thrust chamber.

Success Story: Improvi

History of the progress of the system from four failures in the Vanguard effort to perfect batting average with Thor-Able

by Frank McGuire

AZUSA, CALIF.—From *Vanguard* to *Thor-Able* to *Delta* represents considerable progress since the beginning of the Space Age, and one second stage has prevailed through all three programs. From an unimpressive record of four failures in the *Vanguard* program, the system progressed to a nine-out-of-nine success record in the *Thor-Able* program.

Aerojet-General Corporation, producer of the system, will turn out 15 second-stage systems for the *Delta* program of NASA under a $6 to $8 million contract. The stage is a modification of the *Thor-Able* version, which in turn is a modification of the *Vanguard* version. AGC will be a subcontractor to **Douglas Aircraft Company** on the program.

• **October launching?**—Delivery of the first *Delta* second-stage system to Douglas by AGC was made the first week of this month. The first launching of the complete three-stage vehicle should be sometime in the fall—about October. The third stage is a solid-propellant system produced by **Allegany Ballistic Laboratory.** Gross weight of the *Delta* vehicle is 100,000 pounds.

The only modification of the *Able* system necessary to enable its use in the *Delta* program is the addition of a coast phase altitude control system.

Along with production of the second-stage system, delivery of which will extend over a two-year period, AGC will provide necessary missile support equipment and technical services.

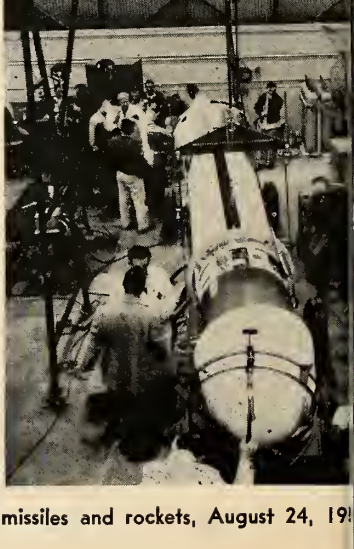
In its *Able* configuration, the system was vital to re-entry tests and deep space probes by the Air Force. The startling thing about this *Able* system is that it moved from idea to initial delivery date in eight weeks.

The entire *Able* system—including test support and propulsion units—was scheduled to be designed, fabricated and tested in 26 weeks. AGC's assignment as of November 27, 1957, was to "produce six rocket propulsion units—to be designated AJ10-40—including systems for attitude control, separation, required airframe structures, and all associated test support equipment." Delivery date was set for May 31, 1958.

The first unit was delivered to **Space Technology Laboratories** on January 17, 1958. It was assembled with other missile systems and shipped to Cape Canaveral for testing.

Initial announcement of the *Delta* contract to Douglas was made April 29, 1959, by NASA, and the first unit was delivered by AGC early in August.

• **Adapted existing engine**—The tight schedule on *Able* forced engineers to adapt an existing rocket engine to the job, and to conduct all component development programs simultaneously. Since basic design requirements were quite similar to those of AGC's second stage *Vanguard* unit, this system was incorporated into *Able*. Two surplus chambers and tank assemblies from *Vanguard* were transferred to *Able*.



Remaining time was devoted to development and fabrication of 18 functionally distinct items of test support equipment and the modification of the *Vanguard* propulsion system. Excluding the tank and thrust chamber assemblies, Aerojet-General developed nine component systems: gimbal actuation system; helium pressurization system; roll control system; interstage separation system; payload separation system; destruct system; vent and relief system; electrical system; and the aft skirt transition assembly and controls compartment.

As incorporated into the *Able* unit, the propulsion system developed about 7800 pounds thrust. The 66-pound engine is regeneratively-cooled and uses a hypergolic combination of unsymmetrical dimethylhydrazine and white inhibited fuming nitric acid as propellants. The WIFNA oxidizer circulated through the 160 pre-form aluminum tubes comprising the cha ber wall. An impinging injector is us offering early ignition at the l chamber pressure of 206 psi.

Pressurization of propellant tanks accomplished by a helium system wh is beefed up by a solid-grain heat g erator when helium pressure drops 200 psi. The solid-grain generator he and expands the remaining helium.

Tank assembly for the system fabricated by welding two cylindri sections to form each tank. They stainless steel, 0.0050″ thick. Her spheres drawn from tapered blar form the tank ends and the heli sphere.

The gimbal actuation system, wh corrects for pitch and yaw duri flight, is capable of moving the thr

he *Able*

chamber plus or minus 3° and is operated by a hydraulic control system mounted inside the aft skirt adjacent to the thrust chamber. Roll stabilization during powered flight consists of two solenoid shut-off valves responding to control system signals, and two pairs of nozzles mounted on the periphery of the forward skirt. Regulated helium gas from the spherical tank is expelled through selected nozzles, two clockwise and two counter-clockwise, depending on the control desired. Each nozzle of the selected pair produces seven pounds of thrust for a maximum of 20 seconds.

• **Simultaneous venting**—The vent and relief system is designed to simultaneously vent the oxidizer, fuel and helium tanks by means of three vent valves. This is designed to provide a fail-safe means of venting all tanks during a sudden pressure build-up, extended hold during countdown, or valve failure.

Four explosive bolts join the two stages of the *Thor/Able* combination, and separation is achieved when the bolts are exploded by a signal from the thrust chamber pressure-switch which detects rising chamber pressure in the second stage propulsion system, and then effects separation.

Pendulum tests of the payload-separation system were conducted with dummy payload and vehicle structures. The 611-pound payload dummy was joined to a second-stage forward control compartment by two explosive bolts. Both the dummy payload and the control compartment, which had been ballasted to 858 pounds, were suspended to simulate flight position. After actuation of the explosive bolts, separation is achieved through four spring-loaded plungers which push the payload away from the vehicle. A high order of reliability was reported, correlating within 5% the separation velocity measured at 1.6 fps.

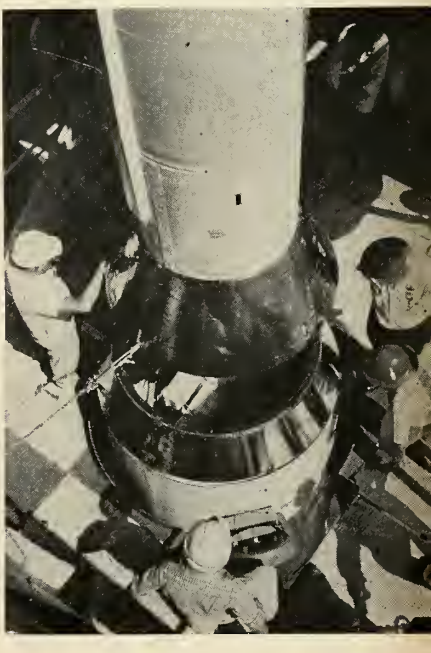
The destruct system, composed of a 15' length of primacord strung along the side of the tank assembly, was capable of completely destroying the second stage in one second.

The first test firing of the *Able* propulsion system was a 10-second calibration run, followed by a 60-second checkout firing. Both took place on Christmas Eve, 1957. Thereafter followed compatibility tests to study overall performance and to determine the effect of gimbaling and roll control jets on propulsion-system performance.

• **Test support equipment**—Two sets of TSE units were built, to be used interchangeably at either the launching area or at the hangars. The original schedule called for the entire TSE package to be delivered and checked out before the first *Able* propulsion system arrived at Cape Canaveral. This was done by building, testing and delivering the TSE within 60 days.

Prime support function of the TSE was multi-fold: pre-launch instrumentation; launch control and electrical systems monitoring; functional pressure checkout; missile-control-system checkout; explosive-bolt and squib checkout; hydraulic servicing; supply and maintenance of system equipment; fuel and oxidizer servicing; missile tank decontamination; propellant-tank drying; and missile handling. The vehicle-handling trailer is a three-purpose vehicle acting as road carrier, lifting sling and as a roll-over and handling frame for inspection and test work.

After thorough testing by Space Technology Laboratories upon receipt of the *Able* stage, it was again completely tested at Cape Canaveral.



During countdowns, there reportedly was no major hold during the *Able* phase of the terminal count. Aerojet says that during each flight in which it was called upon to operate, "the second-stage *Able* fired, and flew a predetermined course down range, delivering its instrumented nose cone within the target area. It thus became the first American missile to fly an intercontinental range of better than 5000 miles."

Spectres Ready for Missile Role

by G. V. E. Thompson
Contributing Editor to M/R

LONDON—The *Spectre* series of kerosene-hydrogen peroxide-propelled rocket engines now in production are intended for both missile and manned interceptor propulsion.

While no information has been released about the use of *Spectre* as a missile propulsion unit, it has a big advantage over liquid engines in that the missile could be held in a state of instant readiness for months without losing oxidant by evaporation.

Manufacturer of the *Spectre* series **—de Havilland Engine Co.**—began work on rocket propulsion in 1946. The first project was the *Sprite*, an ATO unit intended for use with Comet I aircraft.

Sprite was a "cold" unit in which hydrogen peroxide was decomposed with calcium permanganate catalyst (later replaced by solid silver). It functioned successfully but never became operational owing to the use of more powerful jet engines. However, out of it was developed the *Super Sprite*, now in use as an ATO unit for the **Vickers** Valiant bombers.

In *Super Sprite*, kerosene is burned in decomposed peroxide (silver-plated nickel gauze is used as catalyst for the peroxide). Normal maximum thrust is 4200 lb., and duration 40 seconds, but they can be varied within certain limits. The engine weighs 620 lb. dry, 1460 lb. when fueled, and has an overall diameter of 20¼" and a length of 117¼".

The propellant tanks and combustion chamber are made of stainless steel. Only the nozzle is regeneratively cooled. The kerosene tank is wrapped around it to keep the engine as simple as possible. The combustion chamber temperature is kept to 1500°C (instead of a potential 2000°C) by employing excess peroxide. Within the combustion chamber is a large cylindrical flame tube fabricated from Nimonic 75 sheet by argon arc welding.

The combustion products flow down inside this tube. A relatively cool stream of superheated steam and oxygen from decomposed peroxide flows down the annular space between the flame tube and the stressed chamber walls, protecting the latter from the combustion products. The two streams are allowed to mix in the nozzle throat.

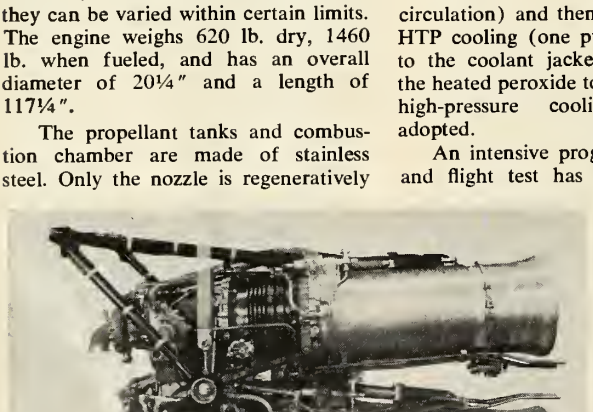
• **Advanced series**—The work on *Sprite* and *Super Sprite* has provided a useful basis for the development of the more advanced *Spectre* series of rocket engine. One of *Spectre's* intended uses was as the main power plant of a manned interceptor aircraft. In design the emphasis has been placed on reliability up to accepted aircraft engine standards.

Although the propellants are still kerosene and HTP, *Spectre* is intended for either "hot" or "cold" operation, so HTP has to be used as the regenerative coolant. After experimenting with an indirect system (in which the chamber was cooled by water which then passed to a HTP heat exchanger before recirculation) and then with low-pressure HTP cooling (one pump delivers HTP to the coolant jacket, a second raises the heated peroxide to supply pressure), high-pressure cooling was finally adopted.

An intensive programme of ground and flight test has been carried out, particularly with the **Saunders-R** S-R.53 research aircraft. Thrusts over 7000 lb. were obtained (the engi is designed to yield 8000-10,000 lb Several different units are no available.

Spectre 5 is a variable-thrust un designed to be capable of running any output between its full thrott power and ground idling. All pump valves and controls are in a compa and robust assembly which can rapidly installed, and is much light than the original *Spectre 1*.

A simplified constant-thrust versi *(Spectre 4)* is also in production. Wh used as an ATO unit, it is designed f repeated use and is mounted within releasable nacelle together with ker sene and HTP tanks and parachu gear. The V-bomber force of the RA **(Avro** Vulcans and **Handley Page** Vi tors) is provided with these units.



• **Newer addition**—A more rece addition to the series is the *Doub Spectre* (D.Spe.D.1). This consists of fixed-thrust *Spectre 4* mounted abo a variable-thrust *Spectre 5*, with on minor modifications to each. The tw units are essentially independent, a though carried on a common tubul frame and connected by certain pip runs. The combined unit is entirel self-contained.

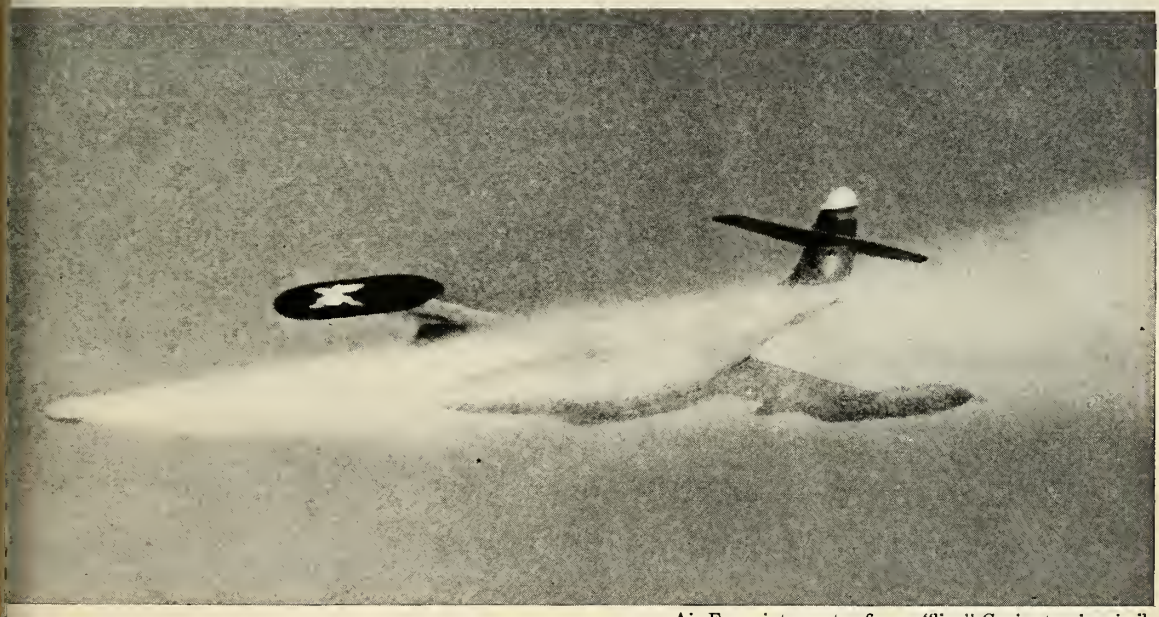
To operate the engine, the pow rocket must first be started. It is fitte with a spherical starter bowl and ca ries a small pressure bowl of nitroge on the starboard side to initiate th start. Once the lower unit is operatin a small bleed of HTP is fed across t energize the turbine of the pump f the upper unit, which can then b started. The whole procedure takes b a few seconds.

The upper unit is either inactive c operating at full thrust; the output c the lower unit is controllable at an value between idling and its maximu thrust. Once started, either unit ma be shut down independently of th other.

Its principal dimensions are: overa length 58.6"; maximum height 37.5 maximum width 36.6".

All the *Spectre* engines are designe so that it is impossible for kerosene t be injected into the combustion cham ber unless HTP was already flowin through.

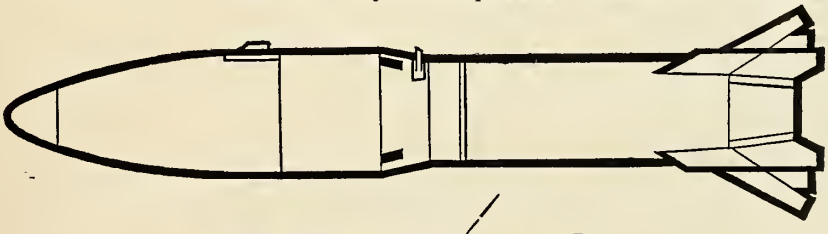
MOUNTING a *Spectre 4* **fixed-thrust engine on frame above** *Spectre 5* **variable-thrust unit produced new** *Double Spectre* **in which the two units are largely independent and can be separately shut down.**



The men:

. . . USAF ordnance technicians assigned to service the Douglas *Genie* air-to-air nuclear-armed missile. They have undergone extensive training in Air Force technical schools and from Douglas field service engineers to become proficient in both rocketry and nuclear ordnance.

The mission:



. . . high-level interception of enemy aircraft. Ideal interception would take place far from U.S. boundaries. The atomic warhead of the Douglas *Genie* was detonated under test conditions over friendly troops with no resultant danger.

Air Force interceptor fires a "live" *Genie* atomic missile

The missile:

. . . the Douglas-built *Genie*. This nuclear missile has actually been fired in flight. Retractable fins allow the missile to nest close to the plane's fuselage. Or it can be carried in the bomb bay. Interceptors can be armed with two *Genies*.

Trouble-free Telemetry Receivers

This small industry—largely in the hands of one company—produces highly reliable and durable units which stay well ahead of their requirements

GROUND receiving station contains four NEMS-Clarke 1400 series receivers.

by Hal Gettings

WASHINGTON—In the hectic flurry of missile research and development at least one vital system part—the telemetering receiver—seems completely competent to handle its important job, today and in the near future.

The specialized radio receivers for missile telemetry have enjoyed a series of steady improvements which keep them ahead of their requirements and promise a continuing capability. They present no real problem in reliability and their operation is generally so dependable that they receive little attention.

The receiver industry is small—and likely to continue so for some time to come. Last year's volume was less than $3 million; 1959 will run under $4 million. And 95% of this business is done by one company—**NEMS-Clarke Division of Vitro Corp.**

There is practically no replacement market for receivers. They have to be repaired and maintained, but they seldom wear out. The first unit developed by NEMS-Clarke, still operating, was built in 1947 for the Bureau of Standards and used for collecting test data on an early parachute-ejection system.

• **Accuracy paramount**—Receivers for missile telemetry must be much more than just good communication equipment. Accuracy of received data is paramount—the receiver must not add any distortion or inaccuracies. Numerous information channels must be crowded in one band and the receiver characteristics must be sharp and clean. Frequency stability must be held within close limits. (Units with variable frequency oscillators provide up to ±0.005%; crystal-controlled units ±0.002%.) Noise figures of less than 8 db, and better, are considered standard. Equipment must be versatile to provide both AM and FM reception —and sometimes CW—and video and audio outputs. Some units feature selectable i-f bandwidths.

This precision and reliability mus be designed in. As a result, equipmen is rather expensive; the best standar units go for around $2500. Many buy ers, though, want a few minor modi fications included—and the price goe up from there. Most in demand woul seem to be a "custom-made standar unit."

• **Limited potential**—There ar probably less than 4000 telemeterin receivers in use today—almost all a missile ranges. The Atlantic Missil Range, for example, has 270 units o one NEMS-Clarke model installed an an unnumbered total of other models

Potential market growth is pretty well limited to two areas: new missil range installations and new telemeterin frequency allocations. It's hard to de fine just exactly how much hardwar will go into these applications, bu estimates are that the business will g along on a slowly increasing level fo the next several years. And, as spac programs grow, the demand for re ceivers will see a commensurate growth

Several major—and many minor— improvements have been made in re ceiver equipment in recent years. Th field has seen no tremendous break throughs, however—possibly becaus none have really been demanded. Mos telemetry people feel that the receive is probably the best and most reliabl part of the telemetry system.

• **Phase-lock progress**—The mos significant advancement has been th development of correlation detection This technique—commonly known a phase-lock demodulation — effectively lowers the receiver sensitivity threshold Gains of from 5 to 15 db have beer realized by the incorporation of phase lock in receiver front ends.

In operation, the phase detector o multiplier compares the instantaneous phase of the FM input signal with that of a locally generated carrier obtained from a voltage controlled oscillator and produces an output voltage proportional to the phase difference. This voltage is fed through an amplifier and

ter network back to the input of the CO which is locked in phase with the coming signal. Since the VCO is following the incoming signal in frequency, the voltage, which causes it to follow in frequency, is proportional to that frequency and thus represents the demodulated output signal.

When the signal input becomes noisy, the ordinary demodulator does not operate properly and the output signal-to-noise ratio deteriorates rapidly. The point at which the demodulator ceases to function correctly is known as the improvement threshold. Phase-lock, by lowering this improvement threshold, increases the sensitivity of the receiver. This is equal, in effect, to increased antenna gain or transmitter power.

No one firm can take full credit for the development of phase-lock. **Radiation, Inc.** several years ago developed an accessory plug-in unit for standard receivers and applied for patents. NEMS-Clarke offers certain models of its 1400 series with phase-lock incorporated.

• **Preamps vs. paramps**—Considerable improvements are expected in low-noise preamplifiers to further increase the sensitivity of receivers. The recently announced "tunnel diode" offers promise in this area.

One industry spokesman feels that efficient advances may be made in tramps to bring them within two db of the parametric amplifier. Problems due to the complexity and stability of the parametric would make the improved preamp more desirable for most applications.

Others feel, however, that the paramp offers a magnitude of improvement not attainable by the other. Especially in the 2200 mc band, the noise temperature seen by an antenna pointed at the sky is low enough to allow the full potential of paramps to be realized.

• **Predetection recording**—One of the most significant advancements in telemetry reception is that of predetection recording. This technique, first used in the reception of radar signals from Venus by **Lincoln Lab's** Millstone antenna, offers great promise in higher reliability of telemetered signals. Receiver input is picked off just ahead of the detection stage, tape recorded, then later demodulated.

The advantage here is in the possibility of applying advanced demodulation techniques to periods in which data are lost due to poor signal-to-noise ratio or interference. Future improvements in this technique are expected to significantly advance long-range telemetry.

Radiation, Inc. has designed and built models of a 2200 mc "state-of-the-art" receiver which provide this feature. Production of commercial models is contemplated.

• **Frequency allocation**—A great hassle has long existed regarding the allocation of frequencies for telemetering use. Today's "standard" band is 215-260 mc and most present receivers are built to cover these frequencies. Predictions are that most of this band will be used at least until 1970. Some equipment is being built to cover the "new" 2200-2300 mc band and it is expected that receiver techniques generally will be advanced as new equipment is developed to fit these higher frequencies. The 1435-1535 mc range is also being used to some extent—primarily for aircraft testing.

NASA has requested assignment of the 135-136 mc band to move the 108 mc Minitrack frequency for future space programs. Although Minitrack is used primarily for tracking, a limited amount of telemetered information is transmitted on this band. A few receivers have been built which cover this band in a spread from 55 to 260 mc.

Generally, the lower frequencies are considered more desirable for their propagation characteristics—and because microwave plumbing in missile transmitters offers problems. Choice is limited, however, by the bands available. Too, missiles are very restricted in the size and type of antennas that can be used—which, of course, has a definite relation to frequency selection.

• **Small business field**—Surprisingly, none of the big radio manufacturers are in the telemetering receiver business to any extent. This is probably because the annual volume is such a small one and that large production runs are not possible. Also, most standard units must often be modified to fit particular applications.

The bulk of the receivers are made by NEMS-Clarke in nearby Silver Spring, Md. This 60-year old firm has been in the field for twelve years. It manufactures a complete line of telemetering receivers and many accessory units such as preamplifiers, multicouplers, and combiner/adders. It heavily emphasizes reliability and goes to great lengths to maintain strict quality control. The company even manufactures almost all its own receiver components—from transformers and i-f coils to plastic panel escutcheons.

NEMS-Clarke produces several series of receivers specifically for FM telemetry. Their 1400 series—with phase-lock in some models—is practically a standard at missile ranges. An estimated 2500-3000 units of their models are currently in use. The company is a leading contender for telemetering receivers for Project *Mecury*.

Tele-Dynamics Inc., formerly **Raymond-Rosen,** was one of the early manufacturers in the field. They built the UKR-2 2000 mc receiver, still being used presently in the *Titan, Polaris* and other missile programs. About 10% of their current business is in receivers; they specialize in miniaturized units for both telemetering and command destruct applications.

Practically all of Tele-Dynamics' business is concerned with telemetering equipment. They claim to be the only company manufacturing a complete system from transducer input to recorder output, including the radio link.

Receivers for all three frequency bands are manufactured by **General Electronics Laboratories,** Cambridge, Mass. They are currently producing one lot of 25 215-265 mc units for the Pacific Missile Range.

TELEMETRY receiving station installed aboard picket ships of the Pacific Missile Range which are deployed to supplement range stations on various Pacific islands.

The Latest Word in Heat Treating

Alco uses a Lindberg furnace with operating temperatures up to 1950° F to treat flight cases for Pershing missiles forged at Latrobe

DUNKIRK, N.Y.—Heat treat of missiles today is a far cry from earlier times, when among other things:

• Armorers quenched the famous swords of Damascus by plunging them into the flesh of the strongest slaves. They believed that the strength of the slaves was transmitted to the steel.

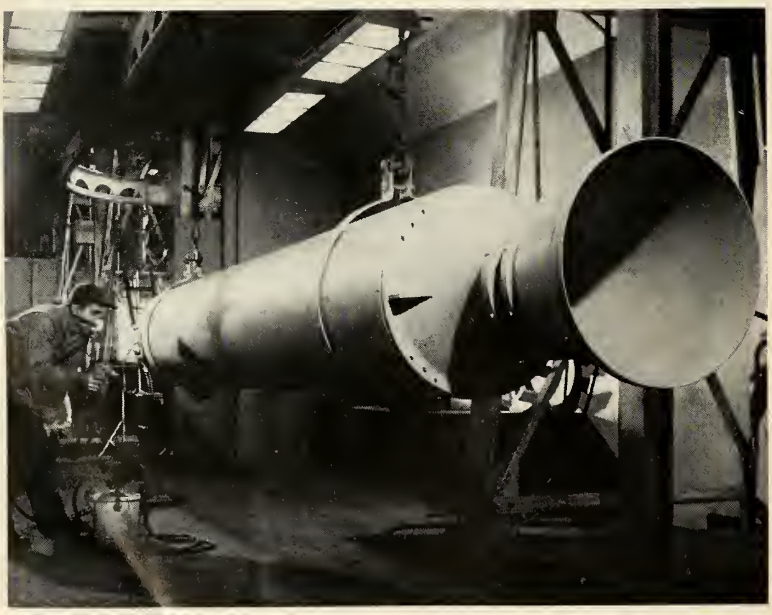
• Metals were immersed in the urine of three-year-old goats that had been fed on ferns for three days.

• The urine of young, healthy, red-headed boys was used.

Little is left to superstition nowadays. Heat-treating facilities are keeping pace with the Missile Age. Metals are quenched after heat treatment in a special oil with temperature specially controlled. The furnaces and tanks all respond to electronic controls, thermocouples and other modern devices.

One of the nation's newest heat-treating facilities, a **Lindberg** electric drop-bottom for missile metals, is installed at the **Alco Products Inc.** plant here. For some six years, Alco has been a key supplier of bodies for the *Honest John*. It has had contracts for making *Nike-Zeus* nozzles and now is producing first-stage flight cases and nozzles for the *Pershing*.

The Lindberg is a versatile furnace. It can perform hardening, stress relieving, normalizing, quenching and tempering, annealing and spheroidizing. Operating temperature ranges from 1400° to 1950°F for 1000 pounds and up to 1650°F for 2000 pounds.



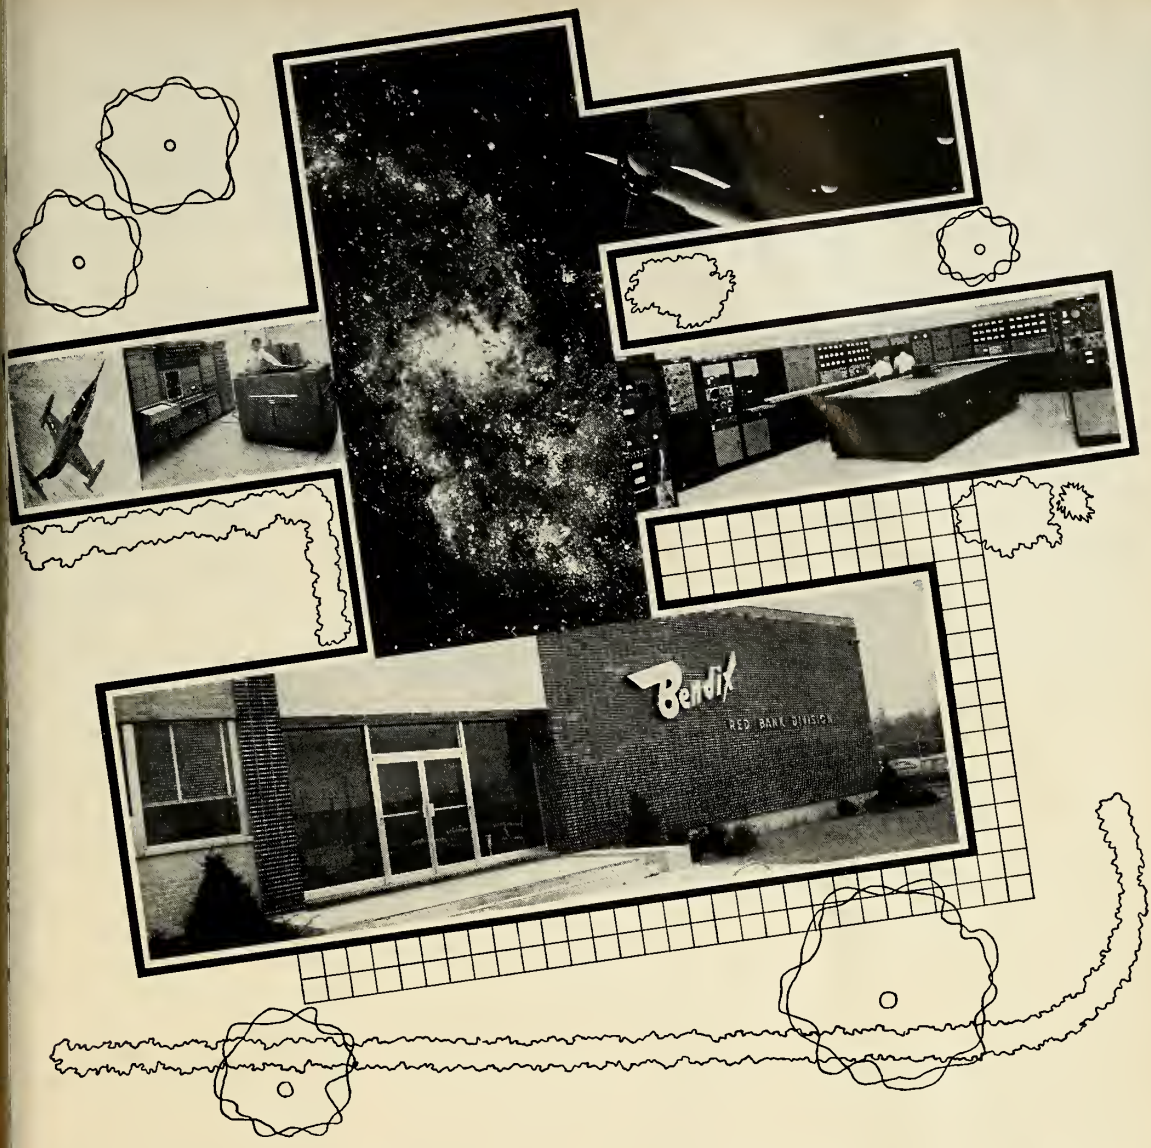
Alco makes motor cases for the *Pershing* on a subcontract from **Thiokol Chemical Corp.,** which has responsibility for the propulsion system. Three precision-made test versions of the motor cases were made first for use in static-fire tests. Later, Thiokol awarded a production order for additional cases, with even more exacting tolerances.

The cases must not be distorted from heat treating in excess of 10 total indicator runout, nor must the 0.105″ skins be decarburized to depth exceeding 0.003″.

The *Pershing* flight case is forge at the Alco plant in Latrobe, Pa. Bot the front and rear heads are hot-presse and contour-machined here. The fro head is hot-formed from ½″ plate an pressed to shape. Then it is roug machined and the center-part forgir is welded in. The head is X-rayed an finish contour-machined to 0.01 thickness.

The rear head is fabricated from seamless forged ring, swaged ar formed to its conical shape and the contour-machined to 0.015″ size. Th shell is formed by rolling and weldir AISI 4130 sheet steel. Then the fro and rear heads are welded to the she to form the case. All welding is dor by automatic Heliarc. Heat treatir brings the yield strength in the 41 case to 180,000 psi.

The **Martin Co.** is prime contracto for the *Pershing*.



ROCKET BODIES for *Honest John* are heat treated in new facility at Alco Products Inc. plant in Dunkirk, N.Y. Prior to shipment, each body receives careful painting.

Semiconductor Can Serve As A Complete Circuit

SAN FRANCISCO—The newest in growing number of microminiaturize semiconductor devices that can ser as a complete circuit was demonstrate here at WESCON by Bell Telepho Laboratories. The device—a p-n-p semiconductor element—is the bas building block of a silicon steppi transistor. It measures only 0.04″ diameter.

The stepping transistor acts as pulse-controlled on-off switch simil to a gas stepping tube. It can be us as a basic stage in certain digital cor puter logic circuits. It is capable many high-speed functions usually pe formed by complex circuitry. Te models of the device have operated speeds up to one million pps. High speeds are expected with improv design.

THE HOUSE WHERE TOMORROW LIVES . . .

Our newest engineering facility, in Eatontown, New Jersey, is dedicated to creating new ideas and products that will help you meet tomorrow's electronic, missile and aircraft needs today.

This ultramodern, completely air-conditioned structure houses the most modern and exact testing devices. Fresh approaches to even the most complex engineering problems are encouraged and facilitated by an environment conducive to imaginative, creative thinking.

Bendix Red Bank's rapid growth since 1941 from a small maker of electrical devices to its present role as producer of a multitude of complex electrical and electronic systems is your added assurance that advanced engineering is a built-in Red Bank feature.

AVIATION CORPORATION

Expansion in Pennsylvania, N.J.

Both states earn upwards of $1 billion a year from missile work; astrionics leads the growth. Second in a series on Middle Atlantic states

by William E. Howard

PHILADELPHIA—Barring a hatch-out of more "bugs," the Air Force in a few weeks will pronounce **Convair's** *Atlas* an operational weapon—the Nation's first ready-to-shoot ICBM. When this missile milestone occurs, it will have particular significance to thousands of scientists and technicians in eastern Pennsylvania and New Jersey. For this hustling industrial area is one of the major subcontracting centers for the big war-bird.

Hundreds of companies in this area are contributing to the development of *Atlas* and dozens of other missile/space systems. Moreover, engineers here hold the prime responsibility for developing BMEWS—ballistic missile early warning system designed to give the country's retaliatory forces 15-minutes advance notice that an enemy ICBM attack is on the way.

Missiles today are an important force throughout the economy of the two states. Defense Department procurement figures and independent estimates place missile-related manufacturing conservatively at more than $1 billion a year in each state. Employment is in the hundreds of thousands. And despite the lack of a major prime missile systems contract, the industry is growing—especially in astrionics.

Much of the activity is concentrated here in the Philadelphia-Camden area. The Big Four of the industry are **General Electric Co., Philco Corp., Burroughs Corp.** and **Radio Corporation of America.** These companies alone employ a total of around 30,000 on missile/space projects and their aggregate contracts run well over $500 million yearly.

GE's Missile and Space Vehicle Department here is developing *Atlas* and Douglas *Thor* nose cones under $168 million worth of contracts. Currently it is working on advanced *Atlas* re-entry vehicle designs in its 120′ shock tunnel which can simulate re-entry environment, including heat transfer, pressures, flow characteristics and other phenomena. Recently the tunnel completed its 1000th firing.

The department also has developed the *Thor-Able* nose cone data capsule recovery system. Its 780 engineers and scientists and nearly 5000 other employees are working on the *Discoverer* satellite series, fuzing and arming *Lacrosse* and *Little John* Army missiles, and pushing R&D on a number of advanced data processing and other projects.

A $700,000 Army contract for *Courier* communication satellite shrouds and code tapes recently went to Philco, which has nearly 5000 employees at its Government Industrial Division here. The company has just received a $13 million follow-on for the Navy *Sidewinder,* which it is co-priming with GE, Utica, N.Y.

Philco in addition has the guidance for Convair's *Redeye*—the Army's new bazooka-type weapon—and the fuzing for *Falcon, Terrier, Tartar, Talos, Little John, Corporal* and *Sergeant.* Philco is now building a new plant for its Transac computer at Willow Grove, Pa.

Just outside Philadelphia in Paoli, Burroughs has a 2000-employee Research Activity which is developing *Atlas* radio inertial guidance computers and electronic devices for a number of other missiles including *Titan* and *Thor.* This facility includes the Ballistic Missile Division of the company—and in the words of Burroughs president John S. Coleman it is the "heart of the participation by Burroughs Corp. in weapon systems programs."

• **Shape of the future**—Across the Delaware River in Camden, RCA—prime contractor for the $1 billion BMEWS (ballistic missile early warning system)—has 15,000 employees at its Defense Electronic Products Division. They are also turning out *Atlas* and *Hawk* checkout gear and working on the Air Force's global communications AIRCOM network, the means whereby SAC will flash the word "Go!" in the event of nuclear attack.

On the plains outside Moorestown, N.J., RCA is constructing the first BMEWS prototype facility. When it's completed, travelers along the New Jersey Turnpike will see something resembling a huge orange sitting on a flat lunchbox.

This full-scale working model of BMEWS installations now under construction in Thule, Greenland, and Clear, Alaska, will be high as a 15-story building—176′. Workmen have completed the three-story base of the facility and will soon finish its top—a gigantic radome 140′ in diameter.

Earlier this month RCA received a multimillion-dollar contract from **Boeing Airplane Co.** for major R&D on sensitive-command and support information networks of *Minuteman's* launch control system.

The whole RCA Defense Electronic Products division is currently doing at least $250 million a year and is growing rapidly.

The missile/space activity of these four major concerns is fostering a profusion of satellite industries. Each company has suppliers, vendors and subcontractors by the thousands. In the past few years many small firms like **Brown Instruments, Suckle Electronics** and **Magnetic Metals,** to name a few in this area, have grown to substantial size.

• **New Jersey electronics**—Missile electronics predominates throughout New Jersey. **Bell Telephone Laboratories** at Whippany is performing for **Western Electric** the R&D on the $450-million *Nike-Zeus* anti-ICBM program. The company's several thousand scientists and researchers also have developed the command guidance system for *Titan* which will be phased out soon by **AC Spark Plug's** all-inertial system.

ITT Laboratories division of **International Telephone and Telegraph**

Corp. has its main installation at Nutley. ITT Labs employs 3500 persons—1100 of them professional engineers and scientists—and they are hard at work on a variety of missile DOVAP (Doppler, velocity, position) guidance systems. Programs include *Lacrosse* and *Talos,* interceptor missile evaluation for *Bomarc* and a number of other contracts running into the millions of dollars.

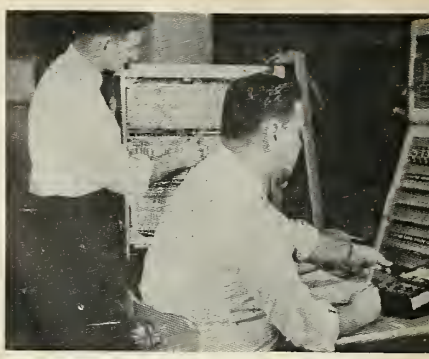
Only recently ITT Labs received an $800,000 Army award for three *Courier* communication satellite ground stations. In the spring, the parent company established a new unit—ITT Communications Systems Inc.—to handle overall development, design and master planning of AIRCOM. RCA is a principal associate.

One of ITT Labs' subcontractors is **Applied Science Corp.,** Princeton, which is now working for ITT on a $794,000 digital data transmission system to be installed at Eglin AFB, Fla.

The Princeton area holds a small cosmos of missile/space research outfits orbiting around Princeton University's aeronautical laboratory, and the Army Signal Corps' Research and Development Laboratory at Fort Monmouth. This latter unit currently has a $190 million-a-year research program underway and is funding work in some 250 commercial laboratories and 50 educational and non-profit institutions.

Kearfott Co. Inc., a subsidiary of **General Precision Equipment Corp.,** Little Falls, is rapidly growing into one of the state's major missile subcontractors. Recipient of a new $4.5-million assignment from Boeing for production of attitude converter systems and related directional control equipment for *Bomarc,* Kearfott is now in the process of building a million-dollar addition to its main plant. The company employs 5000 now and expects to increase its payroll shortly.

• **Elsewhere about the state—Avion Division** of **ACF Industries,** Paramus, is working on a $435,000 NASA contract for transistorized radar beacons to track the *Mercury* manned space capsule; **Daystrom Inc.,** Murray Hill, a leader in anti-submarine detection devices and producer of missile/space instrumentation, is clipping along at an annual sales rate of $76 million.



Thiokol Chemical's Reaction Motors Division, Denville, employs in the neighborhood of 1600 persons. Second largest division of the company, Reaction is producing liquid propellants, including storables and advanced packaged fuels. In the engine line, it produces the powerplant for **North American Aviation's** *X-15* rocket plane; *Guardian I* and *Guardian II* rocket engines for the Navy and the engine for the Navy's *Bullpup* and *Covus* air-to-surface missile which homes on radar.

Other New Jersey companies deep in missile work include **Airborne Accessories,** Hillside; **Curtiss-Wright Corp.** at Carlstadt; **Walter Kidde & Co.'s** Aeronautical Division at Belleville; **Gulton Industries** in Metuchen; **Hydromatics Inc.,** Livingston, and **Thomas Edison Industries,** West Orange.

• **Atoms and cryogenics**—Across the state of Pennsylvania there is increasing missile activity—chiefly in the support field. **Westinghouse Corp.,** Pittsburgh, is manufacturing the nuclear powerplants for nine *Polaris* submarines. Each sub costs $100 million.

Westinghouse a few weeks ago established at Pittsburgh an astronuclear lab where scientists will develop nuclear energy for outer space.

U.S. Steel, Bethlehem Steel and **Crucible Steel** are among the state's heavy industries involved in R&D and production of high-strength, high-temperature steels for missiles. Earlier this year Crucible reported a 25% increase in sales of vacuum-melted alloys for jet engine parts, bearings, missile and electronic parts. Sales have jumped for

MORE THAN 200 persons are employed in Burroughs' Ballistic Missile Division at Paoli, Pa., near Philadelphia.

the **Beryllium Corp.,** Reading, as missile makers find more applications for the lightweight metal.

Still another maker of missile steels is **Latrobe Steel Co.,** Latrobe, which this year put into operation a new vacuum arc melting furnace with a 6 million-pound annual capacity output.

In addition to its New Jersey operation, Thiokol's Reaction Motors division has a plant at Bristol, Pa., which is now working on a $3.5-million production contract of *Guardian II* prepackaged rocket engines.

Air Products Inc. at Allentown has grown into a major company apace the missile/space age. It supplies 90% of the liquid oxygen used in the missile program and has a host of industrial customers. It is in the process of building a $6-million facility outside Pittsburgh at Glassmere to produce high purity LOX, liquid nitrogen and liquid argon.

There is missile activity in virtually every corner of the state. The Naval Ordnance Plant at New York is making the launching system and power driver for *ASROC* surface-to-underwater anti-submarine rocket and the assembly and test of *Weapon A.* At McKeesport, the **National Tube Division** of U.S. Steel is fabricating the war head for the Navy's *Bullpup.* John R. Hollingsworth, Phoenixville, is principal subcontractor for generator sets and frequency changers in the *Nike Ajax/Hercules* series. **Hamilton Watch Co.,** Lancaster, is providing safety and arming devices for *Sidewinder* and *Tartar.* **Landsdowne Steel & Iron Co.,** Morton, is making the rocket head for *Zuni.*

There are many more companies producing components and support items and the list is growing. As one industrialist put it recently: "Missiles and spacecraft are the vehicles carrying us into the future. For the company that doesn't climb aboard now—there many not be any room later."

NOSE CONE of *Atlas* built by General Electric's Missile and Space Vehicle Department in Philadelphia is checked by GE technician at Cape Canaveral.

New Regulation May Slow Procurement

DOD officials fear that new 'rider' will further complicate negotiating job

by Betty Oswald

WASHINGTON—"The time is coming when two sets of secretaries will be needed at the Pentagon"—This was the prediction of a long-time Defense Department employee as he left the Puzzle Palace for greener pastures.

The prediction was based on the strong belief that top civilian officials would be forced to spend more and more time on Capitol Hill, leaving less and less time to do the planning and the paper pushing that is required to make a decision and perhaps more important, to make the decision stick.

Now there is new evidence of the need for more top level officials. It is a small rider which the Congress attached to the Military Construction Authorization Act. It provides, simply enough, that beginning with fiscal 1961, Army, Navy and Air Force must request and obtain authorizations for the purchase of missiles, aircraft and warships.

This means that top-level civilians and military officials will be required to justify their procurement programs before four committees of the Congress, the two Armed Services Committees and the two Appropriations Committees, which seemingly will double the time that these men must spend on Capitol Hill.

But time is only one small factor in the new complications added to the already cumbersome process of first preparing, then submitting and finally justifying defense programs.

• **How much detail?**—Perhaps the most difficult question which the rider creates is: "How much detail will the House and Senate Armed Services Committees really want?" Will they want to authorize specific numbers of aircraft and missiles at specific prices or will they know merely that in a period of five years, the plan is to outfit—numbers of squadrons of intercontinental missiles to cost an estimated number of dollars, leaving to the Appropriations Committees the job of approving the specific plans to buy a specific number of missiles in support of that program each fiscal year? Defense Department officials hope that this is all the Armed Services Committees want.

They are afraid, however, that following the pattern of the construction authorization, the House and Senate Armed Services Committees will really want to get down to specifics. In the construction authorization hearings, Pentagon officials are asked to justify the need for everything from machine shops to bachelor officers quarters, including the number of units.

Any such detail when applied to missiles and aircraft, and even more particularly to spares would almost inevitably bog the whole budgeting process down indefinitely. Yet it is hard to expect that Congress will ask for any less detail, since the legislative rider was not passed until after Congressional Committees had repeatedly expressed their dissatisfaction about the way money was appropriated for one program and used for another without consulting the Congress.

• **Wasted time?**—As Defense officials see it, every trip to Capitol Hill takes time needed for other jobs. While it is recognized that the Congress, as it controls the purse strings, must know what goes on, it is equally true that Congress can't do the programming but must leave the job to the military experts and to their civilian masters. Old timers say, however, that Congressional concerns are valid—particularly because decisions to cut down on required programs are based frequently on the hard facts of economic life rather than changes in legitimate military requirements.

As matters now stand, the hope is for a compromise when the Defense Department and the House and Senate Armed Services Committees sit down together early next year to spell out the ground rules needed to implement the rider.

Issues which must be decided include:

(1) The amount of detail the committees will want to provide necessary authorization. Do they want numbers of aircraft and missiles? Is ground support equipment to be included?

(2) Timing of authorization requests so that they won't get in the way of the appropriations bills. It is necessary that authorizations precede appropriations or the appropriation for a given program may become invalid for purely technical reasons.

(3) A definition of what is meant by "procurement" of "operational" missiles, aircraft and warships. Nobody is quite sure whether spares and repair parts are to be included. Also there is some variation in definition by the services as to what constitutes an "operational" weapon.

(4) Test and evaluation of new-weapon systems is now funded out of procurement accounts. DOD officials want to know whether these items will have to be justified or whether test and evaluation ought to be removed from the procurement accounts and handled as research and development. In some cases, this becomes a difficult problem because production for inventory and research and development for product improvement move ahead at the same time.

What does this rider mean to industry? The answer is that it could mean nothing at all. However, what is considered more likely is that contract negotiations will be bogged down on occasion while waiting for both authorizations and appropriations. Programs on which the industry bases its own planning are likely to be changed more often—once as a result of the shift in Defense planning and once as a result of Congressional action.

• **Biggest problem** — However, everyone seemingly agrees that the biggest problem created will be to find the time—time to prepare the justifications needed for authorization—time to appear on Capitol Hill before both sets of committes and finally time to reconcile differences between the Armed Services and Appropriations Committees. End result is that the already drawn-out process of contract negotiation will be delayed still further and the apportionment process by which the Defense Department gets the funds needed to operate will be slowed.

Biggest hope is that when the Congress receives a report from the Pentagon which shows current programs and how the Defense Department is planning to finance them that there will be a change of heart and the rider will be repealed.

NASA to Try Moon Orbit in October

Space agency to use Atlas-Able vehicle which was earlier scheduled for Venus probe

by Paul Means

WASHINGTON—The National Aeronautics and Space Administration will attempt to place a payload in orbit around the moon in early October.

The vehicle to be used, an *Atlas-Able,* was originally scheduled for a Venus probe in early June. The most advantageous date for the moon orbit attempt at Cape Canaveral would be within a few days either way of Oct. 8 —the date when the moon is furthest south.

The *Atlas-Able* vehicle will hurtle its approximately 200 lb. payload into space at just a little less that escape velocity—approximately 24,000 miles per hour. After the payload leaves the atmosphere, the external aerodynamically shaped shroud will be thrown off, exposing the approximately 70 lb. solid retro-rocket developed for the vehicle by the **Atlantic Research Corp.**

At a point around 200,000 miles from earth and 40,000 miles from the moon, the moon's gravitational pull will exceed that of the earth, and the vehicle will approach the moon. Near the point of closest approach, the retro-rocket will be fired, reducing the payload's speed by about 1,500 miles per hour, and placing it into orbit around the moon.

• **Objectives**—The instruments in *Atlas-Able*'s **Space Technology Laboratories'** payload, which is similar to the payload sent aloft by *Thor Able III* in *Explorer VI,* will allow NASA scientists to learn much about the moon's magnetic and gravitational fields.

Other objectives of the experiment are to learn the properties of cislunar space, of the moon's mass, and to gain information about the moon's configuration, surface details and composition, atmospheric composition and density, and radioactivity.

• **Moon's unseen side**—The STL-developed facsimile system, somewhat like a TV camera, which is presently transmitting pictures of the earth from *Explorer VI,* could reveal in some detail for the first time the unseen side of the moon. This unit consists of a tube containing a mirror which receives and focuses light and dark impressions, and an electronic counter which computes and records the impressions before they are converted into radio signals.

A new device to maintain temperature control in the instrumentation compartments—currently being tested in *Explorer VI*—will get a real workout in the *Atlas-Able* moon orbiter. Surface temperatures on the moon range from 212°F on the sun side to –243°F on the dark side. The unit, developed by STL, relies on the absorption and reflection qualities of black and white surfaces, and operates when preset high and low temperature extremes are reached.

Information from the moon-orbiter will be relayed from a tiny electronic brain called "Telebit," also used on the *Explorer VI* experiment. "Telebit" is a digital unit responsible for the gathering and relaying of data concerning scientific data received by the payload's instruments. The instrument not only collects data, but stores and calculates it before transmitting the totalled data earthward via radio signal.

• **Ground stations**—Receiving the data from the moon orbit payload's ultra high frequency payload will be the large Jodrell Bank radio telescope near Manchester, England and the Air Force's 60 ft. diameter dish in Hawaii.

The *Atlas-Able* vehicle consists of an *Atlas* with **Aerojet General's** second stage *Vanguard* engine and **Allegheny Ballistic Laboratories** third-stage *Vanguard* engine on top. It is capable of sending 200 lb. payloads into deep space.

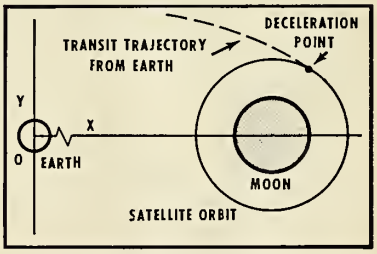
In order to leave its moon orbit and return to an eliptical earth orbit, all that *Atlas-Able's* payload would need is an additional solid rocket capable of increasing its speed by 1500 mph. This would allow it to escape from the moon's gravitational pull, which is about 1/5th that of the earth.

If successful, the *Atlas-Able* will be succeeded by instrumented hard and soft landings on the moon, and eventually, manned flight around and to the earth's satellite.

Other vehicles NASA hopes to utilize to put unmanned orbiters around the moon are *Thor-Delta,* which could orbit 65 lbs.; *Atlas-Hustler,* which could orbit 250 lbs.; and *Vega,* which could orbit 980 lbs.

Rough landings will be attempted by *Thor-Delta,* with a 50 lb. payload, and *Vega,* with a 650 lb. payload. Soft landings will be attempted by *Vega* with 430 lbs., *Centaur* with 730 lbs., *Saturn* with 1700 lbs., and *Nova* with 19,900 lbs.

Vehicles expected to orbit the moon and return to earth with their instruments are *Centaur* with 275 lbs., and *Saturn* with 700 lbs. *Saturn* is also expected to soft land 200 lbs. on the moon and return part of the payload to earth.



Manned lunar landings and return with a payload of 2100 lbs. will be attempted by *Nova.*

ABOARD the USS Norton Sound, a high-performance *Tartar* surface-to-air guided missile leaps from its launcher and streaks toward its target off the Pacific Coast. The supersonic Convair *Tartar* is about 15 feet long and slightly more than a foot in diameter. This photo was made from a stationary high-speed sequence camera mounted on the Norton Sound's after-deck.

USS Boston is armed with *Terrier* missiles. Total of 27 ships will have them.

Navy Wants Huge Fleet of Missile Subs, Ships

But tight money picture may force it to choose between limited-war carriers and proposed missile-space plans. Second in series on DOD planning.

by James Baar

WASHINGTON—The time: The late 1960's. The place: The oceans of the world. Beneath the surface some 50 *Polaris* submarines wait on station. On the surface cruise a score or more of *Polaris*-packing warships.

Meantime, Navy task forces built around attack and ASW carriers stand ready around the earth.

Ships and planes bristle with whole arsenals of new and improved missiles. Navigational, communications and reconnaissance satellites flash far overhead.

These are the strategic pictures framed in the minds of top Navy officials as they struggle with their new budgets and plan against the dangers of the coming decade.

Their approach is a two-fold one designed to meet what they see as the double threat of total and limited war. Their prime problem is lack of money. They need billions more each year to do what they feel they ought to do.

The **Lockheed** *Polaris* is the Navy's top claimant for scarce dollars. But the Navy also needs money for such missile/space projects as:

- A wide variety of satellites—both permanent and temporary.
- New and improved ASW weapons for both detection and kill.
- Development of families of cheap missiles designed to carry conventional warheads.
- *Polaris* **beef-up?**—The cost of the *Polaris* program already has passed the $2 billion mark. However, this is nothing compared to what the Navy would need to employ fully the missile's potential capabilities.

As of today, the Navy has received authorizations and money for a fleet of nine *Polaris* submarines and some long lead-time items for three more.

Navy officials talk in terms of building a fleet of about 50. Moreover, the Navy would like to deploy the *Polaris* on cruisers and possibly carriers and battleships.

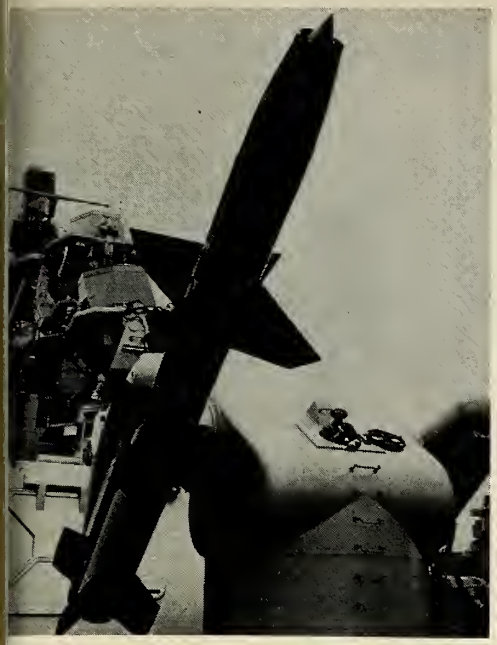
Polaris tubes would be installed in the decks of cruisers and now mothballed battleships. They would be attached as pods to the sides of carriers.

Cost of nuclear-powered submarines for *Polaris* is running about $100 million each. Cost of installing *Polaris* on cruisers and carriers is considered relatively small as long as facilities for only half of a 16-missile round are involved. But the cost of converting cruisers and battleships into huge Polaris launching platforms would be much greater. The total cost for subs and surface ships alone could range from $6 to $10 billion.

However, the Navy contends that the security the nation would get from a mighty fleet of *Polaris* submarines and warships is well worth the price.

Each *Polaris* submarine carries 16 missiles. Cruisers and carriers could be quickly converted to carry eight apiece and new cruisers can be designed to carry a full round of 16. A fully converted cruiser or battleship could carry 100.

A fleet of some 50 *Polaris* submarines and a score of warships could rain more than 1000 megatons on Russia.



Such a devastating launching would be impossible to prevent. The fleet would be scattered throughout the Atlantic and the Pacific, the Indian and the Arctic Oceans. It would be on the move continually. It would be impossible to cripple it by surprise.

No place in the Soviet land mass would be safe from a retaliatory attack by the 1500-mile range missiles except for the small area around Alma Ata in the deep interior of Kazakh. And Navy plans to extend the range of *Polaris* would leave no part of Russia a sanctuary.

The first *Polarises* scheduled to become operational late next year probably will have a range of about 800 to 1000 miles. However, the Navy expects to extend the range rapidly to 1500 and later to about 2200.

The Administration-enforced ceiling on military spending has left little room for a rapid early build-up of a large *Polaris* fleet. And there is no indication of much change in the Administration's attitude.

The Navy this year sought authorization for three more *Polaris* submarines. It got the long lead time items, instead. It probably will seek a new block of nine *Polaris* submarines next year. At best, it probably will get three past the Bureau of the Budget. It has sought authority to install *Polaris* launching facilities aboard some cruis-

FIRING of mock-up *Polaris* missile from an observation ship. Navy wants many *Polaris* ships.

FIRST ship to be equipped with *Talos* was USS Galveston. Present shipbuilding program calls for seven cruisers armed with *Talos*.

ers. But the Joint Chiefs of Staff has tentatively shelved the plan.

•Space entries—The Navy's move into the national space program is increasingly determined.

Transit—the navigational satellite—is being developed by the Navy for ARPA. The Navy is fighting hard to keep it when it becomes operational. The Navy also feels it has a strong need for communications, weather and reconnaissance satellites.

In this line, the Navy is devoting its considerable in-house abilities to the development of equipment for operations in space rather than to development of equipment for getting into space.

Moreover, the Navy can be expected to play an increasingly greater role in missile and satellite tracking. It has developed part of ARPA's satellite detection fence. And earlier this month it disclosed Project *Tepee*—a high-frequency radar system capable of detecting at intercontinental ranges an ICBM launching seconds after the missile leaves the pad.

Finally, the Navy is taking the approach of closely watching all space developments for possible application to Navy missions. Some ideas already under more or less active consideration are development of:

• An anti-satellite missile for use against enemy reconnaissance satellites.

• A reconnaissance satellite that could be launched in the air from a carrier-based plane.

• An anti-missile system for protection of ships.

• An anti-submarine satellite—possibly for early warning of missile launchings from submarines.

In the missile field, the Navy is expected to move ahead as rapidly as possible with the development of such new missiles as **Temco's** *Corvus* and **Bendix'** *Eagle*.

Corvus is an air-to-ground missile that homes on radar. It is designed to attack heavily-defended ground installations and ships. Its engine is powered by a packaged liquid propellant.

Eagle is a nuclear-tipped air-to-air missile. It is designed to fly at high speed after being launched from relatively low speed aircraft.

Both of these are long-range programs. And the missiles are considered high priced.

In contrast, the Navy is extremely interested in the development of a school of "poor man's" missiles carrying conventional warheads.

Navy officials consider that they already have a "poor man's" air-to-air missile in the **GE/Philco** *Sidewinder*. They also feel they have a "poor man's" air-to-surface missile in the **Martin** *Bullpup*.

However, they are still looking for a "poor man's" surface-to-air missile. And at the same time they would like continued improvements in both *Sidewinder* and *Bullpup*.

One *Bullpup* improvement already planned is the increasing of its warhead from a 250 to a 1000-pound bomb. There also are plans to develop a small nuclear warhead for it.

A possible candidate for a "poor man's" surface-to-air missile is the **Convair** *Redeye* now under development for the Army. Navy experts are considering the possibility of adapting *Redeye* for use on landing craft.

But how fast any of these programs will be able to move—or whether in the end some will survive at all—is again dependent on how much of the thinly spread Navy budget can be devoted to them.

One of the Navy's toughest financial problems is the maintenance of its carrier strength in the face of increasing opposition from many quarters.

The Navy feels that it must have 14 attack carriers to maintain U.S. overseas commitments. This fleet at present is comprised of four 76,000-ton Forrestal Class carriers, three of the 62,000-ton Midway Class and the rest of the World War II Essex Class.

By the mid-60's the Essex and Midway Class carriers will be worn out. That will leave the four Forrestal Class carriers, two more that are under construction and the nuclear-powered Enterprise—a total of seven.

Congress appropriated a small payment this year for another Enterprise Class carrier after a bitter struggle. It is open to question whether the money ever will be forthcoming for completing its construction along with the construction of six more to replace the other aged carriers. More than $3 billion would be needed.

A new twist for **KARAK***
SPINNING "HONEST JOHN"

*carbon-graphite
by Ohio Carbon Co.

This is resistance in the dramatic extreme, to...

- thermal shock
- pressure shock
- erosion,

employed as a nozzle insert in the Thiokol M7A1 rocket motor used to give the "Honest John" surface-to-surface ballistic missile a greater degree of accuracy by imparting a stabilizing slow spin.

soviet affairs . . .

By DR. ALBERT PARRY

Launcher-trains for missiles . . .

Some time ago, American experts on Russia's vassal states in Eastern Europe suggested that Soviet IRBM bases, when established in Poland, Hungary, Bulgaria and other "people's democracies," may take the form not only of "hard" launching pads of permanent type, but also of a "soft," more flexible and less vulnerable kind—moved about on flat railroad-cars specially designed for the purpose. Although suitable for solid-fuel rather than liquid-fuel missiles, such launchers on wheels could in time (it was felt) be developed for liquid Soviet IRBM's, too. Whether or not such Red launcher-trains are already a fact, the Soviet government may indeed consider them a necessity.

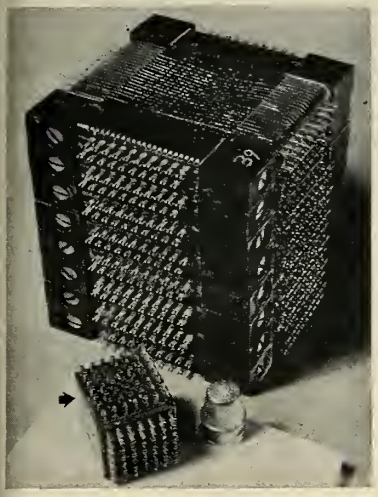
Political vulnerability of IRBM bases . . .

in vassal territory is what the Soviet government wants to reduce. Despite all the shrill words Khrushchev utters on the subject of "love" allegedly felt by the East Europeans for his Russia, in reality there is ever a danger of sabotage, particularly if war does break out, sabotage by Poles, Hungarians and other captive nationals against the Soviet Russian masters and their armaments on vassal soil, including Red missile-launching sites.

Putting IRBM's on railroad wheels may give the Red missiles a mobility that would reduce their vulnerability, a safeguard not alone against Western weapons, but also against those native guerrillas.

Similar U.S. plans . . .

for missile launcher-trains have recently been made public for our solid-fuel *Polaris* and *Minuteman*. For the *Polaris* the recommendation of railroad wheels was included in the report of the President's Committee to Study the U.S. Military Assistance Program headed by William H. Draper, Jr. Plans of trains for the *Minuteman* have been presented by the **Bethlehem Steel Company** and the Los Angeles missiles engineering firm of **Paul Hardeman, Inc.**



The main thought here is to reduce vulnerability of our missile sites as threatened not by sabotage at home (which we have lesser cause to fear than the Soviets have in Eastern Europe) but by the foreign foe's action. The consideration of expense is also important. Launcher-trains would cost less than permanent missile sites.

Expense as Soviet consideration . . .

Yet the point of expense may be applicable to the Soviet ledger, too. On his recent visit to this country, Soviet First Deputy Premier Frol R. Kozlov said to Vice Admiral Hyman G. Rickover that the Red government was cutting down on its atomic research and production because this nuclear program's cost had turned out to be unexpectedly high. Kozlov blamed Soviet scientists for leading their Communist government into too much expense. If Kozlov wasn't lying to Rickover (which is of course quite possible), the Kremlin's worry about the expense is valid not only for Soviet atomics but also for Soviet rockets and missiles (these have nuclear warheads, after all!). Reducing the cost of the nuclear and rocket-and-missile effort may well now be a goal for the Russians.

Where best to establish Soviet missiles? . . .

It may be worthwhile to hear from Khrushchev himself on the subject of best terrain for the establishment of his medium and short-range missile bases. In a speech to Albanians, on the occasion of his visit to their country early in June, Nikita said that Albania and Bulgaria had "exceptionally favorable conditions to put up rocket bases." He elaborated: "Mountains are high there, gorges are deep; that's the place to put our rockets."

Memory Stack's Size Reduced 50 Times

A new miniaturized memory stack for coincident current systems, whose physical volume is 1/50th of the conventional stack, has been developed by the Applied Logics Division, **General Ceramics Corp.**, Keasbey, N.J.

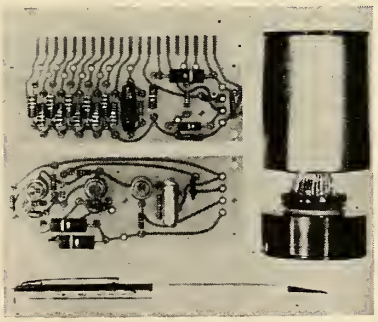
Improved design and assembly techniques, making possible the wiring of ferrite memory cores at a density rate of about 3.5 million per cubic foot, have produced prototype stacks consisting of 2048 cores in a unit measuring only 1 x 1.4 x 1.4 inches. This compares with a conventional stack measuring 3½ x 3½ x 4 inches. In each case the device consists of eight 16 x 16 arrays. Production models will be available in September.

The stack is said to increase reliability by sharply reducing the number of solder connections—in the case of the 16 x 16 x 8 unit from 1056 to 96. It also shortens lead lengths.

The stack, which is said to have as low a noise ratio as conventional stacks, is made up of .050-inch memory cores, the smallest in current usage. The original ferrite memory core and the .050 size were developed by General Ceramics.

Applied Logics Div., General Ceramics Corp., Keasbey, N.J.

Tiny Solid-state Decade Counter Module Produced



A miniature Decade Counter Module featuring a minimum of component parts has been announced by **Burroughs Corp.** Electronic Tube Division of Plainfield, N.J.

Called the DC-110, the new unit combines solid-state devices and the Miniature Shielded Beam Switching Tube in a circuit which is capable of resolving pulses at 250 KC rates. Electrical outputs are provided to operate remote Nixie Indicator Tubes, printers, and to perform other circuit functions.

The unique combination of transistors and the Beam Switching Tubes in the DC-110 makes possible a number of advantages never before available. Examples are: total power consumption of only two watts; elimination of as many as 90 components from the counting circuit; and increased reliability due to component reduction and use of the ultra reliable Beam Switching Tubes.

The DC-110 is designed as a plug-in module for use in computers, electronic counters, machine control, automation and test equipment. The units are directly cascadable and can be driven by a twelve-volt signal. The electronic and visual outputs which are provided suggest their use as preset or variable scale counters and as active elements in electronic systems, particularly where useful work must be performed.

Burroughs Corp. Electronic Tube Division. Plainfield, N.J.

Infrared-Transmitting Materials Improved

Reduction in cost of optically polished domes and windows for infrared-guided devices and enhanced transparency as far as 8 microns wavelength, even despite the blinding effect of re-entry heating, can be expected from a newly developed optical material, **Eastman Kodak Company** has announced.

Domes, prisms, and flats of the new material are already being molded, ground, polished, and sealed to metal by the company under the designation "Kodak Irtran Optics, Type AB-1". Interference Filters to pass specified infrared bands can also be produced on the new material.

In structurally adequate thicknesses, the Type AB-1 "Irtran" material is described as transmitting more than 90% of impinging energy from 3 to 6 microns. The company's tests indicate that the high transparency is retained at 800°C and even beyond. This eliminates the "hot window" effect, where image-forming radiation is drowned out by the emissivity of the optical parts themselves. Other effects of severe heating, as well as those of thermal shock, weathering, humidity, and abrasion, are said to be overcome in the "Irtran" material.

Refractive index of the substance at 6.7 microns is low—1.301. Reflection losses at "Irtran" surfaces are therefore so small as to obviate need for coating, the company feels. Microwave characteristics are close to those of natural mica for insertion losses and reflection in the 9 and 10 kilomegacycle range.

High-Power Silicon Transistors Produced

New high-power silicon transistors, which, when operated as a switch, are capable of controlling over 5 kw of power, have been demonstrated by the **Westinghouse Corp.**, Pittsburgh, Pa.

According to D. W. Gunther, manager of the Westinghouse semiconductor department, "These are the highest power transistors, in either germanium or silicon, that have yet been developed. Although these first devices are still in the prototype stage, we expect commercial quantities to be available soon."

These transistors are suited for high-power switching and linear power applications since they have the following characteristics: collector-to-emitter voltage ratings from 30 to 200 volts; maximum operating junction temperature of 150°C; and saturation resistance less than 0.1 ohm. With a minimum current gain of 10 to 15 amperes collector current, these devices

have a maximum collector current rating of 30 amperes.

Because of the higher temperature capabilities of silicon, one of these transistors can be used in applications that previously required a number of germanium units in parallel. The low thermal drop from junction to case, coupled with this higher temperature capability enables these power transistors to dissipate up to 250 watts internally.

The predecessor to these high-power silicon units, a five-ampere silicon transistor, is ideally suited as a driver for this new 30-ampere device.

These new units use ultrapure silicon produced by the Siemens-Westinghouse process. They are of n-p-n configuration and use a new case that is specifically designed to take advantage of the high current and high voltage capabilities of the new device. The case is of double-ended construction and is hermetically sealed.

Mr. Gunther added that these devices can also be applied in high-power d-c to d-c and a-c to d-c converters;

d-c to a-c inverters; high-power d-c regulators for current and voltage regulation; and in high-power linear amplifiers.

Westinghouse Electric Corp.
Box 2278
Pittsburgh 30, Pa.

Converter Allows Input of Tape to Plotters

A new converter which makes possible the direct use of digital magnetic tape as input to automatic graph plotters and similar voltage devices is being manufactured by **Benson-Lehner Corp.** of Los Angeles. It eliminates the necessity for transferring data from magnetic tape to punched cards, and more than doubles plotting speeds even for existing plotters.

The unit has solid-state switching circuitry and can be adapted to magnetic tape from any digital computer. Selection of data by patchboard makes special programming unnecessary.

Unusual features of the Benson-Lehner Converter include a point density selector, automatic file and record run-up, parity check, off-scale error count or stop-plot, and provision for omitting records which contain specified characters.

Benson-Lehner Corp.
11930 West Olympic Boulevard, Los Angeles 64, Calif.

Digital Indicator Has Servo Null-Balance

A new servo null-balance digital indicator, Type 6R, has been added to the line of continuous reading indicating instruments of the Cox Instruments division of the **George L. Nankervis Co.**

The type 6R digital indicator features high-accuracy multichannel readout for measurement of flow, pressure, speed or frequency with pulse producing transducers.

This instrument qualifies for precision laboratory, production and process applications with an accuracy of plus or minus 0.25%. Linearity is plus or minus 0.25% at any point over a 10 to 1 range. With four digit readout, the Type 6R has a resolution of up to one part in 9000.

Ten scale ranges, with various cross range speeds, are available. This instrument presents an analog numerical readout which continuously follows both increasing and decreasing transducer output. An analog output voltage is also provided for use with oscillographs and recorders for measuring transients and high-speed fluctuations.

The unit contains a completely electronic frequency converter, which supplies the servo null-balance system with a dc voltage proportional to the transducer output frequency. A built-in, tuning fork controlled frequency standard supplies calibration frequencies with check points at 60, 120, 600, and 1200 cps.

The digital indicator can be supplied for one, two or three channel operation with manual and/or automatic channel switching. Span and zero adjustments for each channel and a specific gravity adjustment common to all channels are located on the front panel of the instrument. A variable damping control stabilizes the readout by smoothing transducer fluctuations

and transcients. A small meter on the front panel shows rapid changes in the measured variable which are not indicated by the damped digital readout.

The unit is available with scale ranges up to 9000. Transducer signals with a minimum output of 10 millivolts and a frequency range of 5 to 40,000 cycles can be read with this instrument. Type 6R has a 500 ohm input impedance and power requirements of 115 volts, 60cps and 80 watts. It is housed in a standard 19" rack mount, 7" high and 12" deep.

Cox Instruments Div., George L. Nankervis Co.
15300 Fullerton Avenue
Detroit 27, Mich.

We are FIRST in
ROKIDE
Applications on the WEST COAST

—and the best evidence we can give you is the following list of customers who have used our services for years:

• MARQUARDT • AEROJET • CONVAIR
• THIOKOL • NORTH AMERICAN
• DOUGLAS • ROCKETDYNE
• AIR RESEARCH • AUTONETICS
• GRAND CENTRAL ROCKET

—and R & D ROKIDE Coatings, as well as all Ceramic Coatings on Missiles Produced in this Area, Including:

• Polaris • Hawk • Terrier
• Minute Man • Aerobee • Sparrow
• Vanguard • Titan • Bomarc
• Super Bomarc • Genie
and many others.

Send TODAY for your Copy of "Metallizing in ALL Its Phases"—then you'll have the complete picture of our services and facilities.

Yes, Just Another FIRST by

METLA METALLIZING CO. of Los Angeles

1233 So. Boyle Ave., Los Angeles 23, Calif.

west coast industry . . .

By FRED S. HUNTER

The time cycle in the fundamental sciences keeps moving faster. Here you have the reason for the **Boeing Airplane Co.'s** increasing interest in scientific research and its construction of a new $2.25 million building for the Boeing Scientific Research Laboratories. "If you aren't in the cycle, you don't know what's going on until it is too late," says Guilford Hollingsworth, BSRL director. "You have to be a member of the scientific research to keep pace."

Boeing is erecting the new laboratory . . .

building on a separate piece of property at Seattle. This is to avoid any possible conflict with security on the various classified projects on which Boeing engineering may be engaged. Boeing already has several foreign scientists at work in its scientific research laboratories and expects to add more. The laboratories engage solely in basic research in the physical sciences for the benefit of the company. There are no plans to do any contract research. The BSRL has 50 scientists on the staff now; they will number 100 when the new building is completed.

Fringe benefits are increasing . . .

faster in the industry than base pay. J. D. Hodgson, director of industrial relations at **Lockheed's** California division, reports that fringe-benefit costs have risen 161% on an hourly basis since 1946 against an average hourly base-rate increase of 80% during the same period.

Increase in production rate of the *Atlas* . . .

is indicated by the $85 million included in the 1960 appropriations bill as a first installment of the move to add eight new squadrons to the nine currently programmed. Each squadron is armed with 10 missiles. Employment also is going up at **Convair-Astronautics.** Net increase in the work force since Jan. 1 is 2318. The total payroll is expected to reach 14,260 by year-end.

Lockheed's California division has been . . .

working with **Hughes Aircraft** on a joint study of a space vehicle designed to carry personnel "commuting" between the earth and a space station for observation purposes or to assist in the actual construction of such a station. Hughes, it might be added, was recently reported to be seeking to acquire a gyro outfit, looking toward diversification into the stable platform field by the time its extensive aircraft weapon systems business (fire controls and guided rockets) reaches the end of the line.

Air Material Area base at San Bernardino . . .

is giving up most of its other logistic support responsibilities to concentrate on the ballistic missile group. It has relinquished control of the **Douglas** B-66 twinjet bomber, the **Ryan** Q-2 *Firebee* and the **Radioplane** *Q-4* drone to Mobile AMA, such aircraft as the **North American** B-45 jet bomber, **Douglas** C-47, C-54 and C-118 transports to Warner Robins and the **Hiller** H-23 helicopter and the **Ryan** L-17 observation plane to Middletown.

This is our last column from . . .

the Pacific Coast. We move East reluctantly. California provides a pleasant way of life. This is one of the big reasons defense companies on the West Coast are strong companies. People like to live here. Political pressures may bring about geographical replacements of contracts. If they do, the Nation's defense will be the loser.

RELIABILITY

is what determines the success or failure of any weapon system at launch and during flight. Here at the Missile Division of North American Aviation, we are constantly striving to improve this most vital state of the art through analysis and evaluation of environmental criteria, system design analysis, statistical test programs, and other advanced reliability techniques. Engineers and statisticians with a minimum of five years full time related experience in aircraft or missile engineering will find this a most stimulating career in present and future efforts under development.

ELECTRICAL-ELECTRONIC ENGINEERS
interested in
Electrical Component Design and Packaging

Expanding programs at Boeing in connection with Minuteman, the Air Force's advanced, solid-propellant, ICBM, have created a number of outstanding openings for engineers and scientists in the field of Electrical Component Design and Packaging. These are challenging assignments with the Electronic Sciences Section of Boeing, an industry leader in the development of advanced systems.

Openings include assignments in:

1. *Analysis of performance and reliability of components under various environmental conditions for electrical power distribution systems and electronic equipment.*
2. *Detail studies of component packaging in vehicle and ground equipment.*
3. *Detail design of electrical power distribution system components.*

If you are interested in the analysis, design and demonstration of electrical components and packaging techniques, you'll find in these openings all the scope you need to develop your career potential to the fullest. You will also enjoy a host of benefits at Boeing, including a retirement plan, paid vacations, insurance programs and an opportunity to participate in company-paid graduate study programs.

propulsion engineering

By M/R STAFF

Dramatic changes in molecular sieves . . .
announced by the **Linde Company** give these sophisticated adsorbing powders a new and vital role in missile chemistry. Modifications developed by the Linde Division of **Union Carbide Corporation** change the molecular sieves from powders that extract undesirable impurities from chemical systems into powders that store desirable ingredients, unreacted, right in the system until reaction is deliberately promoted by heat or addition of another chemical.

'Chemical-loaded' molecular sieves . . .
as Linde calls them, may ease handling and storing of difficult fuels and ignitors. Company scientists also cautiously predict that the combustion characteristics of certain fuels may improve when they are loaded onto molecular sieves. Anti-oxidants and anti-ozonants for rubber and plastic gaskets, tubes, etc., already have been successfully loaded on molecular sieves, and many compounds that may be useful in high-temperature lubricants have been adsorbed.

Resembling white powders . . .
the sieves are synthetic metal-alumino silicate three-dimensional crystals containing water of hydration. Heat will drive out the water without collapsing the crystal lattice. The particle diameter ranges from one to three microns. They are inert to most chemicals except strong acids. Linde first made molecular sieves available in 1954. The new chemical-loaded sieves were announced last year, but Linde has just published detailed properties and suggested uses. The original sieves were removal agents used primarily for drying gases—including hydrogen and hydrocarbons—drying liquids including alcohols, other hydrocarbons and fluorocarbons, and for separating gases.

Sieves work this way:
Each particle of sieve powder is a crystal containing billions of cavities connected by channels of constant diameter. The uniform channel size and strong surface force isolate compounds contained in the crystal "cages." Compounds remain confined until released by heat or displaced by another adsorbable material. This is what led to their new use as carriers for chemicals. The sieve can "carry" a chemical into a mixture and keep it there, unreacted but ready for action. When it is time for the chemical to play its part, it is released by heat or displacement with water or another chemical.

Four major uses are:
(1) Isolate adsorbed chemicals within a solid, liquid, or gaseous system until release from the molecular sieve is desired.
(2) Establish an atmosphere in a confined space by slow displacement of the adsorbed chemical over an extended time.
(3) Reduce odor, noxious or dangerous properties, or volatility of many chemicals.
(4) Store chemicals for prolonged periods.

Some types of chemicals . . .
which have been successfully loaded on sieves include alcohols, peroxides, hydrocarbons, halogens, acid gases, organo-metallics, amines, ethers, aldehydes, ketones, esters, anhydrides, organic acids, and water.

Other types of chemicals . . .
cannot be loaded on molecular sieves: Compounds whose molecules have a critical diameter larger than 10 angstroms (e.g., cross-linked polymers, proteins, certain polycyclics); thermally unstable, low volatility compounds insoluble in nonpolar solvents; inorganic salts; metals.

Recovery Failure Mars *Discoverer V* Success

WASHINGTON—*Discoverer V* soared into orbit Aug. 13 handling ARPA and the Air Force a new success and a mysterious failure.

The **Lockheed** satellite was launched from Vandenberg AFB Calif., by a modified **Douglas** *Thor*. The entire 1700-pound second stage—called *Agena*—went into a 450-136 mile orbit.

The *Discoverer* achieved stabilization in a desired attitude and maintained its position in orbit. This is the second time in the launching series that a *Discoverer* has achieved stabilization—a key step toward development of a reconnaissance satellite.

The *Discoverer* also ejected its biomedical capsule as scheduled over the Hawaiian Islands area on Aug. 14. But Air Force and Naval units failed to recover it.

The failure was officially said to have been caused by loss of communication with the capsule. Recovery teams received no signals.

However, the loss of the signals was understood to have been caused by a malfunction in the capsule apparently resulting in a bad re-entry.

'Munitions Lobby' Probe Nears Temporary Halt

WASHINGTON—The House Armed Services Subcommittee investigation of the so-called "munitions lobby" is moving toward a temporary halt in its public hearings.

The subcommittee probably will adjourn its public interrogation of top industry and military officials until the winter—possibly December. (M/R Aug. 17)

Subcommittee staff members will use the interim period for following up on a number of matters that have come up during the current series of hearings.

The subcommittee in recent days has spent much of its time questioning military legal officers on what kind of legislation might be written to check possible pressuring of the Pentagon by retired military officers employed by defense contractors. The legal officers testified generally that they would put their reliance on the basic character of military officers. They shied away from proposals for tough new laws.

The subcommittee also heard a number of influence charges from Columnist Drew Pearson including an allegation that Dr. Richard Porter of **General Electric Co.** got the Pentagon to switch the *Vanguard* engine contract from **Reaction Motors** to GE. Pearson said the switch enabled Russia to beat the United States in launching the first satellite.

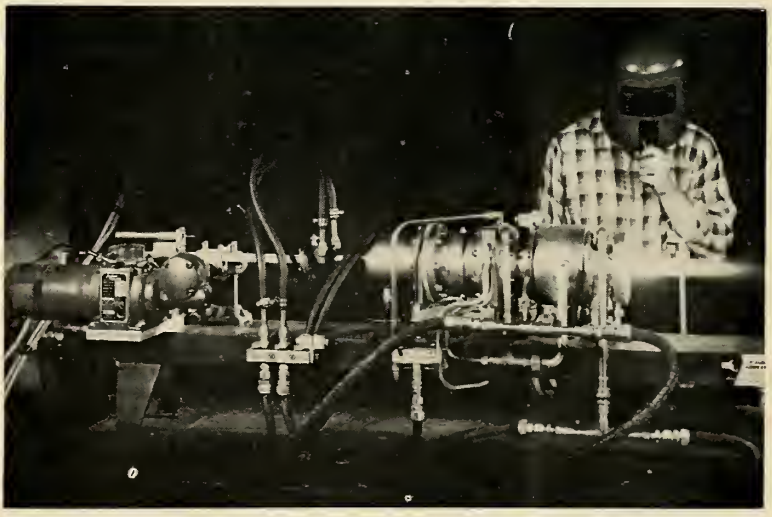
However, Pearson conceded under questioning that he had no "proof of influence peddling."

Porter denied Pearson's charge and called for an opportunity to rebut it before the subcommittee.

Steel Shipments Drop

In the first half of 1959, reports American Iron & Steel Institute, ordnance and other military groups (excluding aircraft) took 97,534 tons of steel, compared to 128,001 tons in the first half of 1958. Aircraft took 43,540 tons, compared to 30,021 tons.

Ordnance's share of all steel shipments was 0.2%, a significant drop from its share of 0.45% in the first half of last year. Aircraft's share of the market changed little: From 0.09% last year to 0.1% this year.



Steel setasides for defense needs are being drafted by the Pentagon. Chances are they will never be used, because stocks of special missile needs are reportedly in good enough shape for a 60-day strike, and the odds are for a settlement before then.

Beryllium extrusions by **Norair Division, Northrop Corp.,** are being developed to individual specifications, as a result of a 1958 survey of the aircraft-missile industry to learn just what engineers wanted from the glamour metal. Three of four builders of missiles and space vehicles will be using beryllium for primary flight structures within five years.

Martin's *TM-76B Mace* ground-to-ground tactical missile has been fired successfully from a simulated shelter, apparently a prototype of hardened base configuration in which the missile will be installed in Europe. The firing was from the AF Missile Development Center, Holloman AFB, N.M., to Wendover AFB, Utah.

Boeing Airplane Co. is consolidating its Systems Management Office, Seattle and Pilotless Aircraft Divisions into a single unit to be called the Aero Space Division . . . New entrant in germanium alloy junction and silicon transistor production is **U.S. Transistor Corp.,** Syosset, L.I., which also has taken over the sales organization of **Super Electronic Corp . . . Avien Inc.** is in the process of acquiring **Luther Mfg. Co.,** North Hollywood, Calif.

AVCO'S PLASMA ARC

FIRST production model of 18,000°F plasma generator turned out by Avco's Research and Advanced Development Division of Wilmington, Mass., was recently purchased by Jet Propulsion Laboratory. The arc was perfected by Avco as part of a materials testing program for re-entry vehicles for the Air Force *Titan* and *Minuteman* ICBM programs. It is the result of a two-year development program.

STEINHOFF

Appointment of **Dr. Ernst A. Steinhoff,** well-known, German - trained missile engineer, as director of its newly formed Missile Department, was announced by the Crosley Division of Avco Corp. Dr. Steinhoff was technical director for flight mechanics, ballistics, guidance and control, and electronics at the German Rocket Research Center at Peenemunde under **Dr. Wernher von Braun.**

Since coming to this country in 1945, Dr. Steinhoff has been chief scientist of the Ordnance Department for the Army at Fort Bliss, technical director at Holloman AFB and has served on the technical management council of the Air Research and Devclopment Command. He served on the Teller Committee in November of 1957 and in March of 1958 received the Exceptional Civilian Service Award of the U.S. Air Force.

Prior to his Crosley appointment, Steinhoff was deputy technical director in charge of Defense Products for the Aerophysics Development Corp., a subsidiary of Curtiss-Wright.

The board of directors of Litton Industries has elected **Charles R. Abrams, Jr., Dr. George Kozmetsky,** and **Harry J. Gray** vice presidents and **William L. Reynolds** secretary of the corporation.

Abrams, who has been treasurer of the company since August, 1955, a post he will continue to hold, joined Litton in February, 1954 as controller. Dr. Kozmetsky, assistant general manager of the Electronic Equipments Division, came to Litton in May, 1954, as director of the company's digital computer and controls development work.

Gray joined the company in November 1954 and has held various management positions in components since. Reynolds, who came to Litton as general attorney on June 1, had previously been general counsel of the Electronic Industries Association.

BAKER

Stanley E. Baker, Rocketdyne, N.A.A., is newly elected national president of the Society of Photographic Instrumentation Engineers. Baker is supervisor of the Photographic Instrumentation department for Rocketdyne and a charter member of the society which elected him to its highest office.

"Rapid diversification" of its billion-dollar-a-year business, according to Lockheed Aircraft Corp. has resulted in the formation of separate aircraft and missile-electronics combinations. each headed by a group vice president.

William R. Mogg has been appointed general manager of Crucible Steel Co.'s Spring Division succeeding **T. T. Crowley,** who has been named vice president and general manager of Crucible Steel of Canada, Ltd. Mogg joined Crucible last year as sales manager for the Spring Division after leaving Cleveland Graphite Bronze Co., where he was sales manager of Special Products.

Max F. Balcom, director-consultant of Sylvania Electric Products Inc., was recently reappointed chairman of the Electronic Industries Association Legislative Policy Committee. Members of the committee, in addition to Balcom, are: **Ben Adler,** Adler Electronics, Inc.; **E. C. Anderson,** Radio Corp. of America; **William F. Ballhaus,** Nortronics, Div. of Northrop Corp.; **Roland M. Bixler,** J-B-T Instruments, Inc.; **Sidney R. Curtis,** Stromberg-Carlson; **L. Berkley Davis,** General Electric Co.; **Philip Dechert,** Philco Corporation; **J. B. Elliott,** Tele-Dynamics Inc.; **Robert W. Galvin,** Motorola Inc.; **H. Leslie Hoffman,** Hoffman Electronics Corp.; **W. F. Joyce,** Texas Instruments Inc.; **Robert C. Sprague,** Sprague Electric Co.; **D. R. Hull** (Ex-officio), President EIA.

BROWN

Herschel J. Brown, assistant general manager since 1956, succeeds Root as vice president and general manager of the Missiles and Space Division. **W. A. Pulber,** assistant general manager, moves into Kotchian's former job as vice president and general manager of the Georgia Division.

Roy B. Williams has been named West Coast Plant Manager for American Machine Division, United States Chemical Milling Corp. as a part of an overall expansion program. The Division produces precision parts for the missiles and aircraft industry. Williams was formerly assistant to the vice president of manufacturing, American Bosch Arma Corp. American Machine Division and head of Operations Support in Arma's integration facilities on the *Atlas* missile program at Convair's Astronautics Division.

Aerojet-General Corp.'s Liquid Rocket Plant at Sacramento has named **Rudi Beichel** project engineer for the *Saturn* space vehicle's second-stage rocket engine.

He will head up the redesigning and modification work necessary for adaptation of the liquid-fueled *Titan* first-stage engines to second-stage use on the *Saturn.* Primary purpose of *Saturn* is to place large weights into orbit.

Beichel has been head of the Special Projects Department, Liquid Rocket Plant and formerly worked with von Braun at the German Rocket Research Center in Peenemunde. Von Braun heads the overall *Saturn* program.

FLYNT

Jerome D. Flynt has been named executive assistant to **Elmer P. Warnken,** president of CTL Inc. Flynt, who has been head of CTL's Technical Services Department, will continue this responsibility until a successor is named. He started at CTL in 1949 while a university student.

L. Eugene Root, vice president and general manager of the Missiles and Space Division since 1956, will become group vice president-missiles and electronics, covering the Missile Division and Lockheed's new Electronics and Avionics Division in Newport Beach and Los Angeles.

A. Carl Kotchian, vice president and general manager of the Georgia Division in Marietta, will be group vice president-aircraft responsible for Georgia, California Division, Burbank; Lockheed Aircraft Service, Ontario, Calif.; Lockheed Aircraft International, Los Angeles; and Lockheed Air Terminal, Burbank.

Neil M. Blair has been elected vice president and assistant to the president of Intelex Systems, Inc., subsidiary of International Telephone and Telegraph Corp. Blair, who will supervise the accelerating expansion of the firm into the commercial and industrial automation and control fields, was formerly vice president of Panellit, Inc., and vice president and general manager of Panellit Service Corp.

Maj. Gen. Thomas C. Musgrave, Jr. takes on the job of handling Air Force legislative liaison on Sept. 10, succeeding **Maj. Gen. William P. Fisher,** who will get a new assignment. Musgrave is now chief of manpower requirements and liaison in the office of the assistant secretary of Defense for manpower, personnel and reserve.

James G. Miles has been elected to vice president for Marketing. Since joining the company in 1957 he has been director of Service Engineering. Miles previously was with Remington Rand Univac as director of Special Sales, Bendix Aviation Corp. and Sylvania Electric Products, Inc. in engineering operations.

NRL Reports Gains in Thermonuclear Control

by Jay Holmes

WASHINGTON—Controlled thermonuclear power—an ultimate source of propulsion for big interplanetary space ships—moved a giant step closer to reality last week.

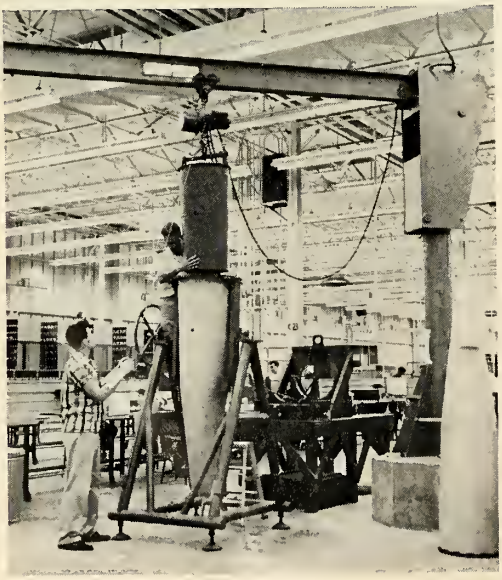
Dr. Alan C. Kolb of the Naval Research Laboratory reported achievement of deuterium pressures consistent with temperatures on the order of 20,000,000°K for periods of 5 to 12 micro-seconds. These results, with high gas densities—upwards of 10^{16} particles/$_{cc}$ are about 10 times as long a duration as ever previously attained.

Kolb made his report at the Fourth International Conference on Ionization Phenomena in Gases, at Uppsal, Sweden. NRL officials here estimated that—as a result of the stepped-up progress—usable thermonuclear power might be produced within 20 years. Dr. C. V. Strain, superintendent of the Laboratory's radiation division, was even more optimistic. He remarked that research in this field is progressing at an ever-increasing rate.

"There is good prospect that on a laboratory scale a controlled thermonuclear reaction has already been achieved," an NRL statement declared. "The results satisfy all the experimental tests which have been applied. However, further tests will be necessary to establish beyond all doubt that a thermonuclear reaction has, indeed, been observed."

Kolb used relatively simple equipment. His experiments cost about $2 million, shared equally by the NRL and the Atomic Energy Commission, over about three years. His device consisted of a cylindrical magnet 12″ long, with a 6″ outside diameter and a 1½″ inside diameter. The deuterium gas is in a tube inside the center of the magnet.

The openings at either end of the magnet are less than ¼″ in diameter, creating a magnet mirror effect, with a field of 125,000 gauss compressed shock preheated gas. A 20-KV, 4-million-ampere pulse in the tube lasts from 5 to 12 microseconds. The current is supplied from a 285,000-joule condensor bank.



NRL's Dr. W. R. Faust said the next experiment should confirm the thermonuclear reaction. This would involve scaling up the present apparatus. The condensor bank would go to 20 million joules. The coil would be 15 cm in diameter and three meters long. He estimated that this would produce temperatures in the neighborhood of 50,000,000°K—possibly enough for a self-sustaining deuterium-deuterium reaction. It would cost another $2 million and take about a year to set up and perform.

The prime interest in controlled thermonuclear power is, of course, its potential for ground-based power, consuming the deuterium of the sea in tiny quantities. But the great efficiency of thermonuclear power also gives it great promise for space propulsion. Specific impulse would be measured not in hundreds but thousands and perhaps millions of seconds.

Many machines have been built in several parts of the world in efforts to tame the thermonuclear reaction—the nuclear fusion process in the Hydrogen bomb. (For a report on Soviet work in this field, see page 13.)

The difficulty in every case has been the instability of the high-current, high-voltage discharge used to generate the multimillion-degree temperatures needed to ignite the hydrogen fire. Kolb's results indicate this difficulty has been overcome.

ASSEMBLING LACROSSE

A CANISTER is installed in the nose section of a *Lacrosse* missile, in production at Martin-Orlando. *Lacrosse* equipment was delivered recently to Army at Ft. Sill, Okla.

Further *Explorer VI* Data Is Disclosed

SAN FRANCISCO—New details on *Explorer VI* were revealed at the WESCON meeting here by Dr. George E. Mueller of **Space Technology Laboratories.**

The satellite has counted one dust particle for every one hundred million cubic feet of space. This is equal to the space occupied by the Empire State building. Dust distribution is apparently uniform to an altitude of 22,000 miles.

The satellite has not found particles of sufficient size or momentum to harm space equipment. There is a larger concentration, however, of low-energy particles—mostly electrons—than had been anticipated.

These particles are on the order of 200,000 electron volts and up, and cover the entire Van Allen belt area. Two hundred thousand electron volts is the lowest energy being measured by the satellite.

There is no data to discourage man in space and Dr. Mueller estimated that a vehicle with reasonable shielding could get safely through the belt while traveling at escape velocity.

Explorer VI has a perigee of 134 nautical miles and an apogee of 22,900 miles. Scientists hope to get a crude facsimile picture of the earth at 10-20,000 miles altitude.

Monitoring instruments indicate that the solar cells are not putting out their anticipated power, Dr. Mueller said. The cells are covered by a glass protection with the exception of one uncovered test cell.

Dr. Mueller said the Van Allen radiation belt appears to be a fine, layered structure instead of one uniform area. The radiation level at 22,000 miles is low and probably would not endanger a manned space station at that altitude.

contracts

NAVY

$9,373,728—**Texas Instruments, Inc.**, for an advancement airborne surface search radar system.

$5,900,000—**Hoffman Laboratories, Div. of Hoffman Electronics Corp.**, Los Angeles, for production of a passive countermeasures system for underwater and surface craft.

$1,389,345—**Paul Smith Construction Co.**, Orlando, for construction of *Nike-Zeus* facilities.

AIR FORCE

$1,500,000—**Consolidated Systems Corp.**, subsidiary of Consolidated Electrodynamics Corp., Monrovia, Calif., for production of ground support equipment for the *Atlas* missile program. (Subcontract from Convair Div. of General Dynamics Corp.)

$1,000,000—**Perkin-Elmer Corp.**, Norwalk, Conn., for alignment theodolites to be used in conjunction with the *Atlas* ICBM. (Subcontract from Arma Div. of American Bosch Arma Corp.)

$780,000—**McDonnell Aircraft Corp.**, St. Louis, for production of *GAM-72* missile and launch gear.

$118,000—**Aeronautical & Instrument Div., Robertshaw-Fulton Controls Co.**, Anaheim, Calif., for special cable assemblies for checkout and launching of the *Atlas* missile.

$90,000—**Raytheon Inc.**, Waltham, Mass., for the study of methods for converting microwave energy into heat.

$73,041—**Graflex, Inc.**, Rochester, N.Y., for camera sets and ground support equipment.

ARMY

$5,317,195—**George A. Fuller Co.**, Atlanta, for construction of *Minuteman* facilities at Patrick AFB.

$4,852,228—**Rheem Manufacturing Co.**, Downey, Calif., for an AN/USD-2 surveillance system.

$4,821,715—**Western Electric Co., Inc.**, N.Y., for engineering services and technical reports in conjuction with UNICOM.

$3,909,999—**Kaiser Steel Corp.**, Los Angeles, for construction of service tower at Patrick AFB.

$3,023,204—**Chris Berg, Inc.**, Seattle, for tracking and data acquisition station.

$2,768,964—**Five Boro Construction Corp.**, N.Y., for construction of *Nike-Hercules* facilities at Robins AFB. Macon, Ga., and Turner AFB, Albany, Ga.

$1,191,070—**Otto J. Eickhof & Sons, Inc.**, Crookston, Minn., for construction of electrical distribution power plant and radar tower for Finley AFB.

$865,700—**Edward R. Marden Corp.**, Brookline, Mass., for construction of *GAM-77/72* facilities at Griffiss AFB.

$806,852—**Diversified Builders, Inc.**, Cocoa, Fla., for construction of blockhouse for space systems launch facility.

$601,407—**R. E. Daily & Co.**, Detroit, for construction of radar tower, Selfridge AFB.

$426,539—**Parsons Construction Co.**, Omaha, Neb., for construction of nose cone facilities at Offutt AFB.

$279,505—**Raytheon Co.**, Newton, Mass., for electron tubes.

$104,000—**C. H. Leavell & Co.**, El Paso, Tex., for construction of *Nike-Zeus* facilities, Walker AFB.

$99,977—**American Machine & Foundry Co.**, Alexandria, Va., for research in the transmitting of beams of ions, neutral atoms and electrons over long distances through space.

$97,320—**University of Wisconsin**, for studies of the three-dimensional structure of the planetary boundary layer.

$92,600—**Sylvania Electric Products, Inc.**, Mountain View, Calif., for electron tubes.

$92,315—**American Machine & Foundry Co.**, Alexandria, Va., for technical and scientific assistance for range instrumentation facilities.

$69,695—**Sylvania Electric Products, Inc.**, Williamsport, Pa., for electron tubes.

$57,112—**Armour Research Foundation of Illinois**, for studies of micro-meteorological surveillance observing system.

BIDS

Rome Air Materiel Area, Att: ROPNA, Griffiss Air Force Base, N.Y.—Transmitter T-282 GR, 1 ea. Modulator Power Supply MD-141 ()/GR, 5 ea. required cable assemblies 5820 NSL, in acc./w Specs. MIL-T-4755A (USAF) dated 12 Mar. '59 and Amendment NR.1 thereto dated 26 June '59. Major spare components equipment and depot spares in acc./w MCP-71-673, Ground handling and special tools equipment and test equipment in acc./w MCP-71-650 and amendments thereto, 300 each. Two each first article will be tested in acc./w MIL-T-9107 and 1 each will be tested by Air Force. A 30-day continuous performance reliability test will be run. Models of similar equipment will be supplied for guidance purposes only. Closing date for receipt of bid requests is 14 Aug. '59.—IFB 30-635-60-47B—Bid opening 21 Sept. '59.

National Aeronautics and Space Administration, Lewis Research Center, 21000 Brookpark Rd., Cleveland 35, Ohio—Power supply, shall be rated at 0 40000 Volts D.C. at 0.1 amperes, continuous duty, current output continuously variable from Zero to 4000 volts in steps on exceeding one-half of one percent full voltage, 1 each. Power supply, high voltage D.C. 0-50 KV variable in steps of not more than one-half of one percent, 2 each.—IFB C-601—Bid opening 8-21-59.

Power supply, D.C., 20/40 volts, 7500/3750 amps, complete with saturable reactor, stepdown transformer—rectifier and balance coil assembly, temperature controller, input-output voltmeters and ammeters—1 each—IFB C-491—Bid opening 8-21-59.

Services, labor and materials for installation and connection of electrical equipment for NASA reactor facility in accordance with our specifications—Job—IFB C-534 PB—Bid opening 8-25-59.

U.S. Army Engineer District, Jacksonville, 575 Riverside Ave, Jacksonville, Fla.—Construction of space systems launch complex 36, AFMTC, Patrick AFB, Fla.—Job—IFB ENG-08-123-60-9 B—Bid opening 9 Sept. '59.

AIR RESEARCH AND DEVELOPMENT COMMAND TECHNICAL SYMPOSIUM, JULY, 1958, WADC, U.S. Air Force, Dec. 1958, Order No. PB151627 from OTS, U.S. Dept. of Commerce, Washington 25, D.C., 502 pps. $7.

This report contains technical papers and discussions of an ARDC symposium on materials for space vehicles and propulsion systems, held last July in Dallas.

Material covered includes papers on such structural materials as aluminum, magnesium, beryllium, steels, super alloys, adhesives, graphites, plastics, and surface treatments.

Special purpose materials such as elastomers, lubricants, glasses, shielding, and textiles are also in the report.

Material on electronic materials include papers on synthesis and application, energy transforming materials, insulation and dielectric materials, magnetic materials, and transistors.

AEROSPACE

ENGINEERS—SCIENTISTS

How about YOUR future?

Here's a company where the past and the present PROVE the future is interesting and worthwhile.

★ **Leadership in Engineering Design**

★ **Leadership in Business Airplanes**

★ **Leadership in Ground Support Equipment**

★ **Diversified Production Contracts**

★ **Winner of Mach 3 Alert Pod Design**

★ **Diversity of Creative Opportunities**

★ **Winner of Mach 2 Missile-Target Award**

★ **Builder of Major Assemblies for Fighters**

★ **Stability of Engineering Employment**

★ **Expansion Programs Now in Process**

BEECH AIRCRAFT has responsible positions open now for specialists in LONG RANGE programs on advanced super-sonic aircraft and missile-target projects in the following aerospace fields:

Human Factors

Analogue Computer

Reliability (Electrical)

Stress

Aero-Thermodynamicist (Heat Transfer)

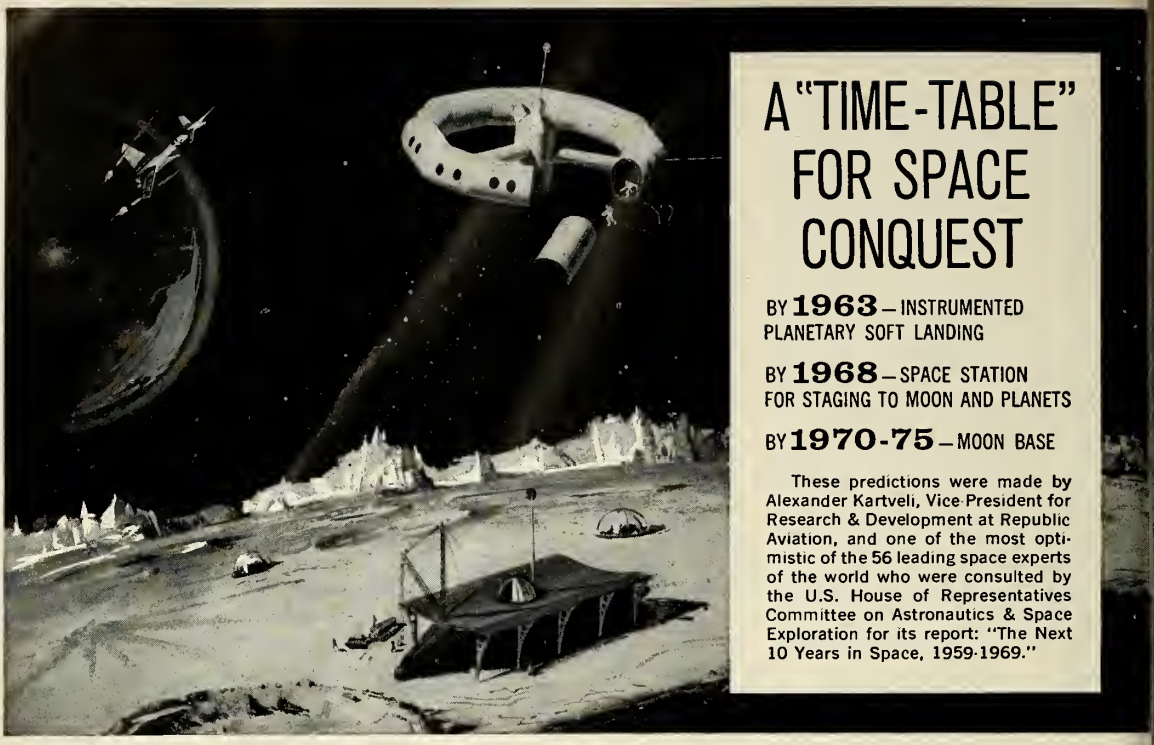
Structures (Basic Loads)

Senior Weight

Dynamics (Flutter)

Systems (Missiles)

Electronic



Electro-Mechanical

Airframe Design

For more information about a company WITH A LONG RANGE FUTURE where your talents will build your own future—call collect or write today to D. E. BURLEIGH, Chief Administrative Engineer, or C. R. JONES, Employment Manager, Beech Aircraft Corporation, Wichita, Kansas. All expenses paid for interview trip.

A "TIME-TABLE" FOR SPACE CONQUEST

BY **1963** – INSTRUMENTED PLANETARY SOFT LANDING

BY **1968** – SPACE STATION FOR STAGING TO MOON AND PLANETS

BY **1970-75** – MOON BASE

These predictions were made by Alexander Kartveli, Vice-President for Research & Development at Republic Aviation, and one of the most optimistic of the 56 leading space experts of the world who were consulted by the U.S. House of Representatives Committee on Astronautics & Space Exploration for its report: "The Next 10 Years in Space, 1959-1969."

JOIN REPUBLIC IN AN **INTEGRATED ATTACK** ON PROBLEM AREAS OF **SPACE EXPLORATION**

It's the fervent conviction of engineers and scientists at Republic Aviation that the courageous "Space Time-Table" above is entirely feasible – given a tradition-free, integrated approach to the problems. Such an approach is evident at Republic Aviation. Here, groups of specialists from many disciplines are working in close collaboration to solve problems across the entire spectrum of space technologies, which limit today's interplanetary and upper atmosphere flight capabilities.

Expanded by $35,000,000 last year, Republic's integrated Research and Development program has already produced signal advances in space guidance concepts; in new propulsion systems (plasma, nuclear); in radiation physics; in new materials and processing techniques; in unique hypersonic configurations; and in prototype development of hardware (as an example: hydraulic systems that operate reliably up to 1000°F).

Professional men—who can meet new challenges with enthusiasm and dedication – are urged to look into openings with our R&D groups, working in an atmosphere of exhilarating intellectual adventure.

ADVANCES IN ASTRONAUTICAL SCIENCES, VOLUME 4. Proceedings of the 5th annual meeting of the American Astronautical Society, distributed by Plenum Press Inc., N.Y. 460 pps. $8.

This American Astronautical Society publication is a record of special lectures and technical papers presented at the AAS meetings held last December in Washington.

The volume includes material grouped under the headings of upper atmosphere research and re-entry mechanics, space vehicle design, guidance and instrumentation, satellite mechanics and space exploration, rockets and satellites, and man's environment in space.

ELECTRONIC DESIGNERS SHOCK AND VIBRATION GUIDE FOR AIRBORNE APPLICATION, published by WADC. Available to Dept. of Defense contractors. Order through Armed Services Technical Information Agency, Number AD-204095. 250 pps.

Written by technicians and scientists from the WADC Electronic Components Laboratory working with RCA electronic engineers, this electronic designers reference manual is devoted exclusively to shock and vibration environments.

The manual includes theory philosophy, vibration studies, electronic component parts and their characteristics, rack and chassis design, damping equipment for simulating and measuring shock and vibration, laboratory test procedures, vibration and shock protective devices; and equipment mounting and installation techniques.

DESCRIPTION OF AFMDC PROTOTYPE CAMERA STATION FOR SATELLITE SURVEILLANCE; Walter E. Woehl and Richard M. Waetjen. Order No. 140 199 from Library of Congress, Photo duplication Service, Publications Board Project, Washington 25, D.C. 47p. Microfilm, $3.30, photocopy, $7.80.

The basic requirements and a description of the philosophy adopted in the determination of accurate orbital data of satellites with the help of ballistic cameras are given.

Coded automatic-shutter operation and correlation to true standard time are described, and the photometric performance of the cameras using different optics is computed.

Data processing and evaluation, and improvements in the basic system are outlined. Sample photos of recordings are included along with a summary of those satellite position determinations which were performed.

Propulsion System Analysts

for theoretical studies of high energy fuels and advanced engine cycles

Chemists, physical chemists, physicists; mechanical, aeronautical, and chemical engineers are needed for an analytical group to compile fundamental high temperature thermodynamic data, to compute theoretical propellant performance, and to study preliminary engine performance and design. This work will include devising simplified methods for using both large and small electronic computers in these studies.

Present opportunities range from senior and supervisory positions for scientists and engineers with appropriate experience, to positions requiring only limited experience.

Located in suburban Richmond, the company offers completely modern facilities, attractive working conditions and opportunity for individual responsibility. Living is pleasant in Richmond and the company maintains competitive salaries with liberal benefit programs.

Integrity Cannot Be Legislated

For days now we have watched a succession of witnesses appear before the Subcommittee for Special Investigations of the House Armed Services Committee to testify on the influence of retired military officers in the matters of defense contracts. Some have been from the Pentagon, but most have been from industry, either the retired officers themselves or their employers.

It would show less than a conscientious regard for us to say the testimony has not indicated that many of these retired officers have been greatly beneficial to the companies which employ them. But we believe that the great bulk of that benefit has been derived from utilizing the same qualities of leadership, wisdom and experience which made these men good generals and good admirals—and not because they could negotiate the sale of otherwise unsaleable products or programs.

We know several companies with tremendous defense contract backlogs which hire almost no generals or admirals in what could be called a "contact" capacity, and one woefully weak in government contracts which employed a half a dozen.

The services which a retired officer can contribute honestly and ethically to a company handling defense contracts are many. It costs, for example, literally hundreds of thousands of dollars and many man hours of skilled scientific labor for a major prime to make a proposal for a major weapon system.

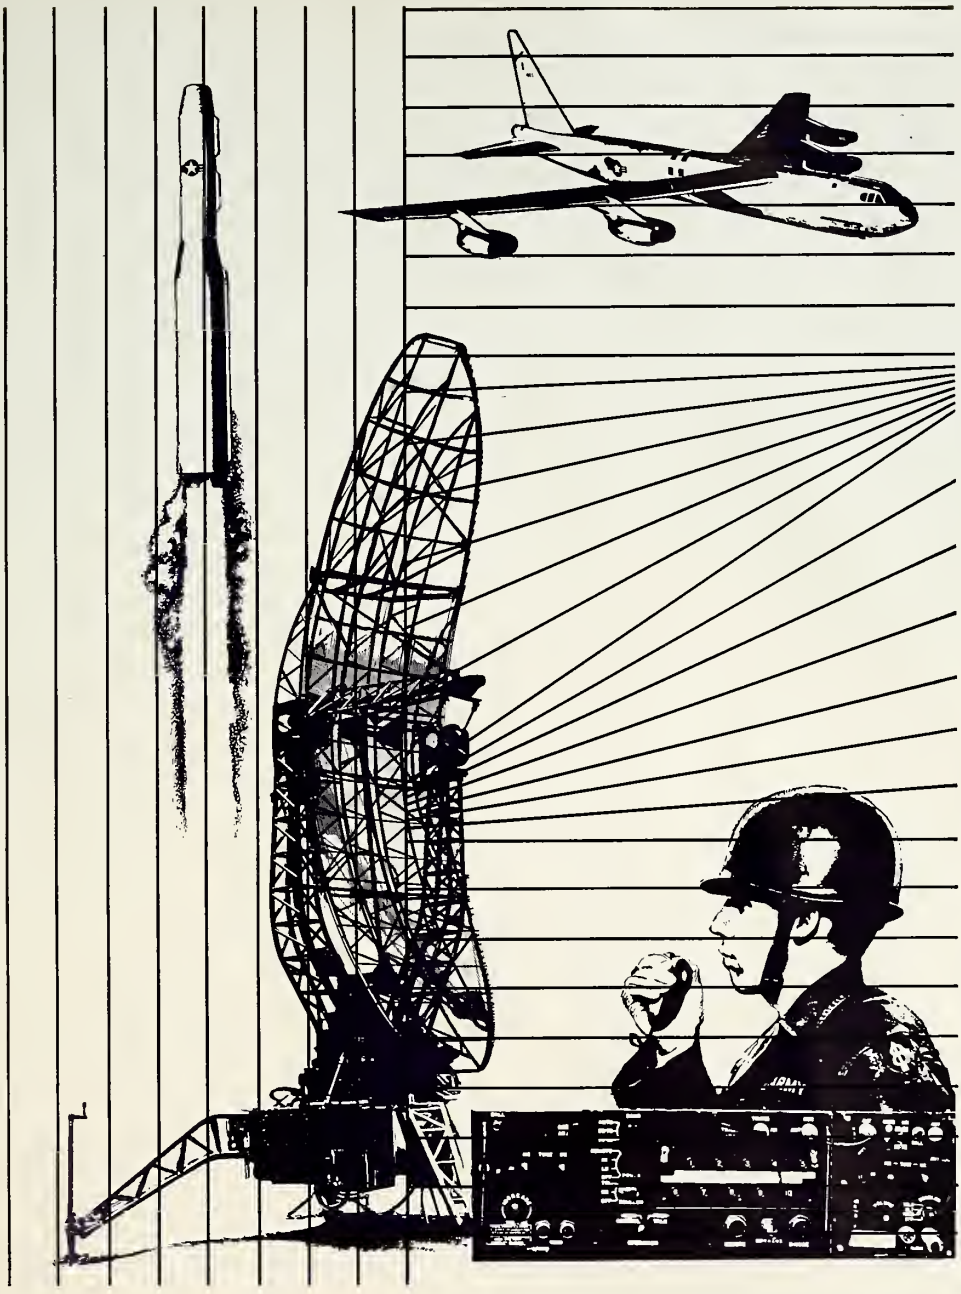
If the retired officer knows which concepts are obsolescent, which have been proven impracticable or simply lead up a blind alley, and if he can prevent his company from heading into that field in its proposal—then he not only has saved his company money but has prevented wasted effort on the part of engineers and scientists whose time and effort the country can ill afford to waste.

It is probable that some new laws will come out of the Hébert hearings to guide the relations of retired officers with both industry and the government. But we suspect they will be inconclusive of any hard result in solving the true problem involved here—the real or fancied unethical practices of the nation's big defense industries.

For this is the heart of the question, and it evolves from the President's casual reference to the existence in this country of a "munitions lobby"; it asks whether or not pressure is brought upon the military by industry to continue weapon systems after they have become obsolescent, pressure to produce competing weapons—and other practices which deviate from reasonable honesty.

The solution for that, we feel, can come from one source and one source only—the Pentagon. Firm and clear-cut decisions must be made there between weapons, weapon systems and which service is going to use them.

There used to be a day when each Service had a job to do and the authority to get it done. Budgets were presented to Congress on this basis and there was a mutual confidence and respect. Somewhere in the dawning of this confusing Space Age the simple system of deciding what is best and sticking to that decision seems to have been lost. So has the time-honored precept of coupling responsibility with authority. On top of the military services, the nation's Defense Establishment has layered board upon board, committee upon committee, agency upon agency—not to make decisions but to delay or avoid them.



This is the area, we think, where Congressman Hébert and his committee must look for a solution. Inertia itself tempts industry to go overly far in trying to force action.

The testimony before the Hébert Committee, some of it inept and some of it strongly perceptive, has not shown any wrong-doing on the part of retired military officers working with the defense industry—and we doubt that it shall.

It would be a great tragedy if it did, for, as the Martin Company's Chairman of the Board, George M. Bunker, said in his prepared statement before the committee:

"In the final analysis, it is really a matter of integrity that we are talking about and I have every reason to believe that the integrity of retired military personnel is of the highest caliber. In any event, integrity cannot be instilled by legislation. However, I would suggest that if there are any real doubts about the integrity of our military personnel, these doubts should be exhaustively explored and at all costs eradicated, for the damage in disservice that a military officer lacking the requisite integrity could do to his country is far greater in his military capacity than it could ever be as an employee of industry."

LING

SINE-O-MATIC SERIES

SINE-O-MATIC Model RP-1/2— Model 227 Shaker
Sine-O-Matics with 25 to 150 pounds force output are available in this vertical rack mounting. Systems for 500 to 1500 pounds force are packaged in a compact desk-type console. All models can be converted to random motion at a moderate cost.

- Extended frequency range—from 5 up to 10,000 cps.
- No impedance changing or manual power factor correction required over entire frequency range.
- All components except shaker are housed in single, compact control console, either desk type or vertical.
- Consoles equipped with swivel casters for mobility—can be easily moved, as required.
- Sine-O-Matic systems meet all specifications called for under MIL-E-5272... can be profitably used by *all* equipment or components manufacturers!
- Fully automatic programming and push-button operation—ideal for production line testing!

REVOLUTION IN DESIGN

Grove Regulators... As revolutionary in design and engineering as the technological transition from flying machine to space vehicle... Achieved a quarter of a century ago, the only regulators which could be used for the first missile experiments in the Navy Experimental Station at Annapolis ... still today the standard for the critical control of high pressure fluids... Now on the threshold of space, Grove is uniquely prepared—through advance research and development—to meet the challenge of even higher pressures ahead.

GROVE POWREACTOR DOME REGULATOR MODEL GH-408-50-6000 PSI INLET...5-3000 PSI REDUCED PRESSURE

Explorer VI is a space laboratory orbiting around the earth with paddles capturing sunlight for power

The scientific data that will some day enable us to probe successfully to the very fringes of the universe is being recorded and transmitted at this moment by the space laboratory Explorer VI, a satellite now in orbit around the earth ● This project, carried out by Space Technology Laboratories for the National Aeronautics and Space Administration under the direction of the Air Force Ballistic Missile Division, will advance man's knowledge of: *The earth and the solar system . . . The magnetic field strengths in space . . . The cosmic ray intensities away from earth . . . and, The micrometeorite density encountered in inter-planetary travel* ● Explorer VI is the most sensitive and unique achievement ever launched into space. The 29″ payload, STL designed and instrumented by STL in cooperation with the universities, will remain "vocal" for its anticipated one year life.

How? Because Explorer VI's 132 pounds of electronic components are powered by storage batteries kept charged by the impingement of solar radiation on 8,000 cells in the four sails or paddles equivalent to 12.2 square feet in area ● Many more of the scientific and technological miracles of Explorer VI will be reported to the world as it continues its epic flight. The STL technical staff brings to this space research the same talents which have provided systems engineering and over-all direction since 1954 to the Air Force Missile Programs including Atlas, Thor, Titan, Minuteman, and the Pioneer I space probe.

Important staff positions in connection with these activities are now available for scientists and engineers with outstanding capabilities in propulsion, electronics, thermodynamics, aerodynamics, structures, astrophysics, computer technology, and other related fields and disciplines.

Inquiries and resumes are invited.

Armco PH 15-7 Mo Stainless Steel Provides Structural Efficiency for Long-Range Mach 3 Aircraft

New precipitation-hardening stainless combines strength at 2000 mph temperatures with producibility, availability and economy.

Armco PH 15-7 Mo Stainless Steel has been selected as the primary sheet metal for the dramatic new air weapon systems—the B-70 Valkyrie bomber and the F-108 Rapier manned interceptor—being developed by North American Aviation, Inc. for the Air Force. Most of the honeycomb panels and other structural parts will be made of this special stainless because it possesses the required strength at anticipated temperatures and a unique combination of advantages that facilitate the design and production of dependable and economical structural elements.

Armco PH 15-7 Mo Stainless Steel—

* Has high strength-weight ratios up to 1000 F.
* Resists deformation at flight stresses and temperatures.
* Is available in practically all commercial forms—foil, sheets, strip, plates, bars, wire, and forging billets.
* Resists corrosion, eliminates the weight penalty of corrosion protective coatings.
* Can be welded and brazed. Brazing is compatible with heat treatment.
* Is formed in soft condition, then hardened by simple heat treatment.

For the airframes, power plants or accessories of supersonic air vehicles, consider the opportunities to economically improve performance and reliability by specifying Armco PH 15-7 Mo Stainless. Write Armco Steel Corporation, 2829 Curtis Street, Middletown, Ohio, for design data and fabricating information.

Washington Countdown

IN THE PENTAGON

Cutting the defense budget pie . . .
for FY 1961 is expected to begin in earnest during the early part of September. During these weeks, Defense Secretary McElroy is expected to begin making some of the key decisions on which service gets what.

• • •

Long faces . . .
will be the uniform of the day no matter what the decisions are, however. The defense budget is clearly frozen for the Presidential election year at $40 billion or less—a figure widely considered by military officials to be inadequate.

• • •

***Discoverer VII* . . .**
is scheduled as another attempt to perfect the ARPA Air Force system for recovering capsules from orbit. The launching of the satellite is expected to take place sometime toward the end of September. Capsules from *Discoverers V* and *VI* apparently burned up during reentry over the Pacific. (See M/R this issue page 48.)

• • •

Name changing dept. . . .
Lockheed's *Sentry*, the ARPA Air Force reconnaissance satellite project, has been rechristened. It's now called *Samos*—as in the ancient Grecian island. However, same project, same contractors, same purpose.

• • •

Missiles for Japan . . .
are in the cards within the next few years. The Japanese are reported to be planning to build an air defense system around **Raytheon** *Hawks* and **Western Electric** *Nikes*. Timing and the political atmosphere in Japan apparently have a lot to do with when the *Nikes* and *Hawks* are set up.

• • •

Missiles from Switzerland . . .
were imported by the Japanese last year for study. Great internal controversy resulted. So far, the 10 **Oerlikon** ground-to-air missiles have never been fired since they were delivered. However, Japanese engineers have dismantled three for study.

• • •

The first operational *Atlas* . . .
firing from Vandenberg AFB, Calif., is expected within the next two to six weeks. The Air Force is still deciding when to try it. However, the Air Force feels sure it has found and cured the *Atlas* ailment—a malfunction of the fuel disconnect valve.

One of the hottest . . .
of ARPA's future space projects—Project *Orion* studies on development of a nuclear-blast powered rocket—has been extended for another year. The $1 million contract went to **General Atomic** which has been conducting the studies.

ON CAPITOL HILL

A new blast . . .
at Defense Department handling of news on missiles and space exploration is included in the latest report from the House Information Subcommittee. The subcommittee particularly is hitting at the withholding of information on space monkeys and a picture of **Martin's** *Titan* as typical mismanagement of the news.

• • •

A new series . . .
of nuclear tests may be sought by Congressmen if East-West disarmament talks at Geneva continue to produce only hot air. Both Congressmen and military officials see the U.S. slipping in development of nuclear warheads for missiles and a possible nuclear-blast powered rocket because of the voluntary suspension of tests.

AT NASA

Drastic cuts . . .
in the billion-dollar-a-year future once envisaged for NASA is the interpretation being put on recent remarks by NASA Chief Glennan. The immediate outlook: A NASA budget ceiling of probably about a half-billion dollars.

• • •

The huge *Saturn* . . .
1.5-million pound thrust cluster being developed by the Army for ARPA probably will be used first by NASA. NASA Chief Glennan as much as said so in recent testimony before a House committee.

AROUND TOWN

Some of the reports . . .
being passed as "the latest" in the Nation's Capital:

. . . South America is seen as a likely future market for U.S. tactical missiles armed with conventional warheads.

. . . Top space experts say they still have no reason to disbelieve the Russian boast that they will be on the moon by October, 1967.

. . . Congress will be the stage next year for an all-out drive to increase the size of the Army.

PRODUCT SUPPORT ENGINEERS

Urgency - Speed - Reliability. These words describe Convair-Astronautics' top-priority program of activating Atlas ICBM bases throughout the United States. Included in this immense task is the job of training Air Force personnel, developing and producing hundreds of technical manuals and providing technical assistance to the Air Force. The Product Support department at Astronautics is responsible for this assignment and to fulfill it must double in size within the next two years. Engineers qualified to participate in this long-range program will find excellent growth opportunities in the following areas:

CUSTOMER TRAINING – Service Training Instructors—Engineers with degrees in ME, AE or EE, or equivalent hardware experience are needed to prepare and conduct continuing 4-6 month courses to Air Force personnel on the Atlas ICBM. This training will include classroom theory and hardware manipulative skills to a high level of proficiency.

Service Training Planners – Men with 2-5 years experience in the planning of industrial and/or armed services training programs are needed for the planning, preparation, editing and publishing of training material for the Air Force. This assignment will also include training standards, syllabuses, lesson plans and training projects.

TRAINER DESIGN – Trainer design engineers (electronic and mechanical) with degrees in ME, AE or EE are needed to design simulators to be used in the training of Air Force personnel on the Atlas weapon system.

FIELD SERVICE – Engineers, preferably with degrees in ME, AE or EE, and field or in-plant hardware experience are needed to act as technical representatives to the Air Force on the Atlas ICBM. Most assignments will be at Vandenberg AFB, Santa Maria, Calif. There will be other assignments as additional Atlas bases become operational. A limited number of San Diego openings also exist in the areas of Field Service Support. A field service bonus is authorized for field assignments in excess of six months. Per diem paid for assignments under six months.

TECHNICAL WRITING – Engineering degree preferred, plus 1-3 years of technical writing experience. Assignments include the writing of engineering reports, maintenance manuals and operation manuals.

Our engineering representatives will be conducting

Army Faces Exodus from Space

To get the facts behind the following story, M/R editors interviewed top-ranking Army officers and officials of the Defense Department and allied U.S. agencies. While no person interviewed would permit the use of his name, all agreed on the basic facts concerned. M/R carries the story after serious consideration, conscious that it will be regarded as highly controversial by many readers.

by James Baar

WASHINGTON—The Army is facing the possibility of having to get out of the space business.

It also is facing the possibility of sharp curtailment or death of the *Nike-Zeus* anti-missile missile.

The cause is two-fold: lack of money and the pressure on DOD and the Joint Chiefs of Staff to stabilize the missions of the three services.

Linked to both is the Army's increasing drive to modernize its divisions with new tactical missiles and all the advanced panoply of Missile Age nuclear and conventional war.

For a long time a minority of the Army's high command has felt the Army space effort was a costly side effort. Now there appears to be a growing feeling in at least part of the high command majority that the Army may be forced out of the space business by the Defense Department.

These officials are understood to be arguing that it might be best for the Army to take the initiative, give in gracefully, reap whatever financial benefits might be had and concentrate on tactical missiles and the scores of almost startling innovations in the horizon for equipping ground troops.

The soul-wrenching problem is understood to be already on desks at the Pentagon's highest levels. A decision is expected within a matter of months at most—possibly in time for the annual autumn commanders' meeting.

Here are some of the key factors:

• The Army for some time has been low man on the Pentagon budget totem pole. Lack of funds has hobbled Army procurement of modern weapons—particularly missiles.

• An extra $1.5 to $2 billion will be needed in the new budget if the Army is to keep development and production of **Western Electric's** *Nike-Zeus* on schedule.

• NASA so far has placed no orders for space work with the Army in 1960 and probably won't in excess of $20 or $25 million. ARPA business with the Army outside of the huge *Saturn* 1.5 million-pound-thrust booster is relatively small.

• The Defense Department is understood to be pressing the joint Chiefs of Staff in earnest for an end to the grab-bag approach to assigning space projects.

Place all of this in the context that the Administration has again frozen the FY 1961 budget at $40 billion or less and you begin to get the sticky feeling of the situation.

The Army itself is clearly torn until it hurts.

It feels that it has a great past and should have an even greater future in space. Its plans for the years immediately ahead have included a whole series of satellites for reconnaissance, weather forecasting, mapping and communications. Beyond these, Army space team thinking had encompassed such projects as spaceports and construction of bases on the moon and planets.

The Army has felt that its Ballistic Missile Agency centered at Huntsville has tremendous capabilities that should be thrown into this work.

Moreover, Army has contended that not to use its capabilities for space work is pure waste. This argument is based on the contested ground that savings resulting from ending space work at Huntsville would be relatively slight. In fact, the costs of tactical missile development at Huntsville—the bulk of the work at ABMA—might go up.

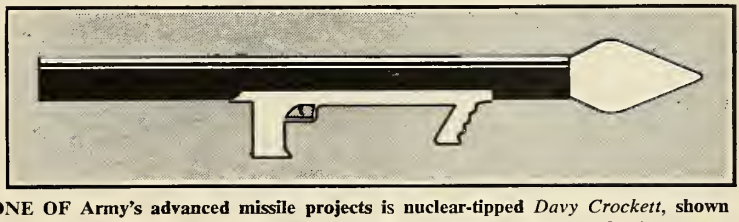
However, many in the Army fear that they face the end of the road into space. Some dozen space projects have been submitted by the Army to NASA in recent months. So far, none of them has been taken up.

This points to another potential question—the disposition of the Huntsville space team should the Army cease space operations. NASA sought to incorporate it once when NASA was organized. The chances probably are that NASA would still be interested, but possibly cooler. But regardless of who runs ABMA, the *Saturn* will keep the space team there busy for some time.

The second big Army problem is *Nike-Zeus*.

Debate on the big missile cuts the Army with a keen double blade. Some feel that *Zeus* is vital to survival; others see it as a costly static weapon that may well never be fired in anger—a weapon that would provide only a defensive role for much of the army of the future.

Zeus—the nation's only foreseeable anti-missile missile for the next decade—is scheduled to be operational by 1963. But this schedule can only be met if funds are provided in the new budget for going into production.



Unfortunately, this is no bargain basement program. The $1.5 to $2 billion which would be needed in FY 1961 is only the first payment. The total price tag would be from $5 billion up depending on how much protection the government wants to buy.

Also, unfortunately *Zeus* is no absolute defense. Therefore, the question arises: Can you buy more defense with $5 or $10 billion by putting your money in more offensive weapons such as ICBM's, *Polaris* submarines and intercontinental bombers.

The Army says no. It says we have enough offensive power planned and in existence. But it says that if the United States is without *Zeus* it will be wide open to Soviet ICBM attack. Moreover, the price of admission will be kept cheap: The Russians will not be forced into improving their ICBM's and will be able to devote the effort to other weapons.

Therefore, some top ranking Army officers feel—although others disagree—that *Zeus* is so vital to American defense that the money for it must be found at almost any sacrifice.

As one official put it: "We could lose an entire Army and it would be a

ONE OF Army's advanced missile projects is nuclear-tipped *Davy Crockett*, shown in artist's conception. Money is lacking to push development of this and other weapons.

great disaster. But we could recover as a nation. But if we are attacked by a large number of ICBM's and have no defense against them we could cease to exist."

If you buy this argument—and it's a tough one to fight—you come directly back to the earthy question of who is going to pick up the bill. Even a casual study of the defense budget makes clear that the billions needed must either come out of the hide of some other program or from a very unlikely budget increase.

This leads directly to the Army's third big problem area: The needed modernization of its scanty divisions to meet the requirements of missile and nuclear warfare.

The Army has not been able to come anywhere near to effecting such a program for lack of funds. It contends it needs millions of dollars more for R&D work on tactical missiles and for their procurement.

Because of funding shortages the Army has been forced to drag out to great lengths the time between development of these relatively short-range missiles and other new equipment and placing them in the hands of large numbers of troops.

At the same time, there is no question that lack of funds has slowed R&D work on the next generation of tactical missiles that will be needed in the mid and late 1960's.

The Army 1960 budget as submitted to Congress originally called for $407 million for procurement of missiles including such newer, advanced weapons as **Martin's** *Pershing* and *Lacrosse* and the **Jet Propulsion Lab/ Sperry Rand** *Sergeant*.

Congress, at least mildly appalled by the lack of speed in procurement of newer weapons, gave the Army an extra $146 million for procurement of equipment including missiles. How much of this money will ever be released to the Army by the Administration is open to question. And, even if the Army were to get it, still more was considered needed and will be again for 1961.

The same thing is true for R&D. Congress gave the Army $1.05 billion —exactly what the budget called for. This includes insufficient funds for development of such advanced missiles as *Davy Crockett* and **Convair's** *Redeye*. And even less for work on the third generation missiles beyond them.

These are the missiles that the Army is depending on to give its divisions the tremendous punch that would be necessary to stand up to the much larger Red forces in any limited war.

For example, nuclear-tipped *Davy Crockett*—an in-house project at Rock Island Arsenal—is designed to be fired from a bazooka tube. The sub-kiloton warheads will vastly increase the firepower of the infantryman.

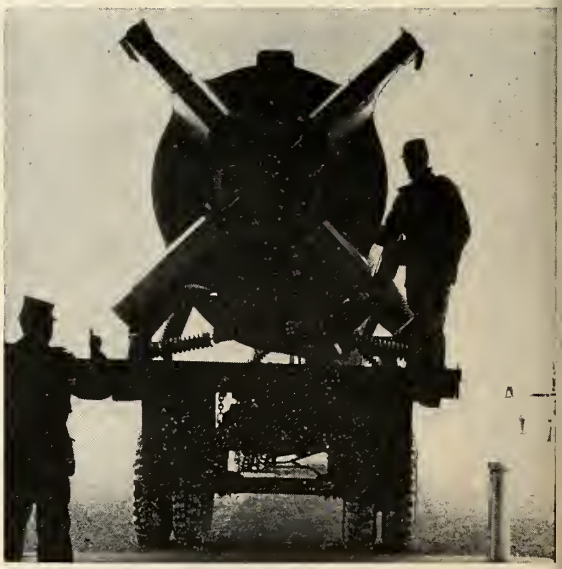
Convair's *Lobber* is another good example of an advanced weapon that is much needed. The missile, for which no funds at all are available, can serve as both a carrier of cargo or napalm.

It is most significant that these funding shortages are not confined to missiles, but run the whole gamut of weaponry. Among some of the most notable skimping is in the field of tanks. Russia today is producing five times as many tanks as the United States each year. In fact, Russia is reported to give its satellites as many tanks each year as are produced in the United States.

Of course, it is against the yardstick of what the Russians are doing that American military power must be measured in the end. Unhappily, the Russians are doing much. Army intelligence says that Russia has completely modernized equipment for its 175 line divisions. These divisions are equipped for fighting either nuclear or non-nuclear wars.

The United States has 14 divisions—most of them incompletely modernized.

Torn by these problems, faced with shrinking dollars, the Army is confronted with far-reaching decisions on these problems as the annual budget battle in the Pentagon nears its height.



The Army has a capability in the space business. The Army sees *Zeus* as vital to national survival. The Army feels that the development and procurement of its own tactical missiles and other equipment is a burning, overdue necessity.

But somewhere something must give sooner or later under the present situation.

Possibly the Army in the end may accept an exit from space in favor of its sister services as a way out. Possibly it might receive in exchange from the Defense Department other considerations. Dollars, for instance.

ARMY wants to develop Convair's *Lobber* to deliver cargo or carry napalm. So far, no funds are available for the bird.

TWO Army groups armed with *Redstone* are on guard overseas. But the service lacks money to proceed with modernization.

Pressing R&D on Refractory Metals

Hundreds of firms are blazing new trails with the heat-resistant materials that promise to answer many big missile-space problems

by S. David Pursglove

WASHINGTON—One of the nation's top missile research efforts is in refractory metals. These are metals distinguished primarily by extremely high melting points. They range from chromium with a melting point of 3430°F to tungsten, which melts at 6170°F. In between are zirconium (3360), niobium, columbium, (4380), molybdenum (4760), and tantalum (5425).

Some chemists, physicists and metallurgists—the primary researchers on refractory metals—also include beryllium (2340), titanium (3020), and vanadium (3450).

Not all metals so classified by melting point are useful refractory materials. Some are too reactive. Some become too brittle. Others are too scarce to merit extensive research that would lead only to demands that cannot be met.

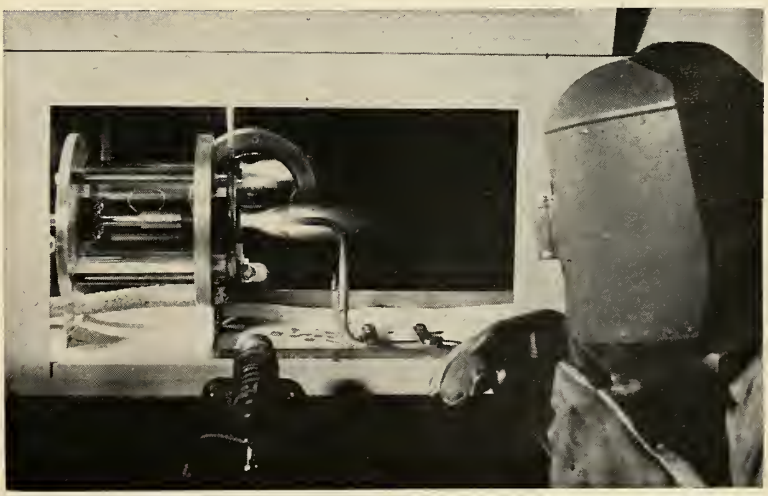
Refractory metals are called the answer to our major space and missile problems. But the metals themselves have some problems that must be solved before they can go to work for us. Research now is directed toward reducing costs, making the almost unmanageable metals easier to handle and fabricate, and devising alloys that bring out the metals' best features. Refractory metals are the subjects of large amounts of basic research. We need to know more about their properties, why they behave as they do (often in very strange ways), and what happens under various conditions.

Wherever refractory metals yield to research effort, scientists, industrialists, and military planners see new horizons beyond what they had thought were natural limits. Refractory metals must have these important qualities.

- They retain their strength at high temperatures.
- They resist oxidation at high temperatures.
- They resist corrosion.

This means that refractory metals can make possible aircraft and missile flight at hypersonic speeds that breed ultrahigh temperatures. It means great increases in specific impulse of conventional fuels may be had, since the hydrogen contained in all these chemical fuels (including kerosene) dissociates above 5000°F—a temperature and effect impossible to achieve with ordinary metals. This means that important, but corrosive, chemicals may be used more readily.

Hundreds of firms—industrial and research, profit-making and institutional—are engaged in refractory metals research.



Research organizations blazing new trails include **Arthur D. Little, Atlantic Research Corp., Battelle Memorial Institute, Stanford Research Institute, Armour Research Foundation, National Research Corp.**

National Aeronautics and Space Administration, Department of Defense, National Bureau of Standards, and the Bureau of Mines are some of the government agencies engaged in some phase of research or development work on the metals.

Private firms working on refractory metals include most of the metals companies, many chemical companies, aircraft firms and missile prime contractors, and several companies that specialize in refractory metals. The latter group includes **Wah Chang, Alloyd, Nuclear Corp., Union Carbide Metals, Beryllium Corp., Brush Beryllium Co., Nuclear Metals, Fansteel Metallurgical** and **Titanium Metals Corp. of America.**

Here is what some companies are doing, at a glance:

- **Marquardt Aircraft** is developing and testing sheet metal structures, particularly those fabricated from molybdenum.
- **North American Aviation** is working with two new compounds that will improve processing of titanium and steel alloys. One compound inhibits formation of scale on stainless steel, nickel-chrome, and alloys of cobalt, titanium, and copper during heat treatment. The other compound prevents

PLASMA JET of ionized air, hotter than the surface of the sun, disintegrates a small aircraft model at NASA's Lewis Research Center, site of much metals research.

gaseous contamination of titanium undergoing heat treatment in an air atmosphere.

• Nuclear Metals is developing casting techniques for beryllium alloys, techniques for working beryllium and zirconium, and extrusion data on most refractories.

• Nuclear Corp. of America is taking a quantitative look at a long-known misch metal phenomenon. Years ago, metallurgists discovered that small amounts of misch metal—mixed rare earths—increased the performance of steels. Later, the same was discovered to be true in the case of some refractory metals. Now, Nuclear Corp. is trying to determine which single ingredient in misch metal is the responsible agent. So far, it looks like the hero is neodymium. And there might even be a villain: cerium. Neodymium alone increases the desirable properties much more than does the misch metal mixture. Cerium seems to decrease creep resistance.

• Alloyd Research is streamlining old processes for vapor phase deposition of tungsten, molybdenum, and chromium on metal and even nonmetal surfaces.

• Fansteel Metallurgical is doing further work on its methods for spinning and drawing larger tungsten pieces.

• **Douglas Aircraft** is conducting basic and applied research in high temperature areas on tungsten, molybdenum, and niobium. Special interest is in niobium alloys for ultra-high temperature leading edges of high velocity aircraft and missiles.

• **Du Pont** is building a center for development research in niobium, niobium alloys and titanium at its Baltimore plant, to be completed in 1960. The center also will have facilities for work with other refractories.

• **National Research Corp.,** Cambridge, Mass., is investigating tantalum and tantalum-tungsten alloys. One promising Ta-W alloy has three times the tensile strength of Ta at 4000°F and is easily fabricated.

• **Bell Aircraft Corp.** is studying refractory metals as candidates for use in the leading edge of *Dyna-Soar* (M/R Aug. 3, page 24).

• **Sylvania Electric Products Inc.** is expanding production of molybdenum, tungsten and other refractories at its Towanda, Pa., plant. Molybdenum ingots weighing 275 pounds are now available and, with a high-temperature sintering furnace being installed, ingots weighing more than a ton will be produced this month. Until recently, tungsten and molybdenum ingots available commercially have weighed less than 100 pounds.

Here are typical comments from government agencies:

Naval Ordnance Laboratory—We are doing some work with refractory metals, but only as they apply to some of our primary projects. Bureau of Aeronautics has a strong interest in this field.

Air Force—Future weapon systems will call more and more on the refractory metals as structural materials. We shall use these metals in hypersonic strategic weapons, ballistic weapons, satellite weapons. (See M/R, July 20, p. 90, for detailed discussion.)

Army—We have a strong interest in refractory metals for rocket motors, and as structural alloys with steel.

• **NASA's work**—For a better idea of how government agencies are approaching this research, look at the program at NASA.

The civilian space agency is interested in refractory metals as a means of overcoming problems that develop at high temperatures, for use in hypersonic aircraft and missiles, and in connection with nuclear-powered vehicles. NASA also recognizes that one way to achieve higher specific impulse from fuels is to heat them above the 5000°F dissociation point of hydrogen. Refractory metals are obviously needed for the containing vessel.

NASA's principal research effort is on niobium and tungsten, with some applications studies on molybdenum structures. The latter work is conducted at Langley Research Center, Va. Actual research work is done at Lewis Research Center, Cleveland.

At Langley, NASA is studying the performance of molybdenum simulated wing panels coated wth nickel-chromium. Out of this work will come one-shot protective coatings for use on leading edges of wings and missile fins above Mach 4 or 5.

Propulsion materials engineer Harold Hessing, of NASA headquarters, says the agency's main interest in refractory metals is in connection with propulsion.

NASA and other organizations have studied niobium for a number of years. Hessing says NASA likes niobium because it has certain advantages over molybdenum: it is easier to fabricate, has better resistance to oxidation, and greater resistance to high-temperature heat transfer fluids.

NASA metallurgists see two major uses for tungsten:

• As a nuclear rocket engine material. NASA is doing some work on tungsten, but the AEC has the primary responsibility in this field.

• As a nozzle or nozzle liner in a chemical rocket.

There are other possible future uses for tungsten, such as in ion beam propulsion and other advanced systems, but any work NASA does in this connection will be incidental to the main effort.

As an example of the immediate need for research on tungsten or other refractory metals, Hessing points to large solid rockets. As these engines become larger, graphite nozzles become inadequate. Metals added to fuels to control resonant burning form oxides that deposit on the nozzles and change their configurations.

However, because of the cost of large, complicated tungsten shapes, NASA and the military agencies are looking at tungsten not as a nozzle structural material, but as a protective coating for graphite nozzles and liner for heat sinks.

As part of its basic research effort on refractory metals, NASA recently awarded a small contract to the University of Denver to study the effect of rare earth additives on the melting of tungsten and molybdenum. If the study sheds new light on ductility, Hessing says, then it may be extended to cover other areas, such as high temperature.

Refractory Metals

Metal	Symbol	Atomic Weight	Atomic Number	Melting Point (F)	Remarks
Beryllium	Be	9.0	4	2340°	Very light; heat sink; reactor moderator.
Titanium	Ti	47.9	22	3020°	Light and strong; cheap as raw material but costly to fabricate.
Vanadium	V	50.9	23	3450°	Very expensive tool steel alloy.
Chromium	Cr	52.0	24	3430°	Retains strength, resists oxidation at high temperatures.
Zirconium	Zr	91.2	40	3360°	Reactor structural material.
Niobium (Columbium)	Nb (Cb)	92.9	41	4380°	Shows most promise; must be coated to prevent oxidation above 2500° F.
Molybdenum	Mo	95.9	42	4760°	Most widely used refractory metal; needs foolproof coating to prevent high-temperature oxidation.
Tantalum	Ta	180.8	73	5425°	Close chemical relative to niobium; higher priced but stronger.
Tungsten	W	183.9	74	6170°	Most important refractory; properties well established through experience in use for light-bulb filaments.

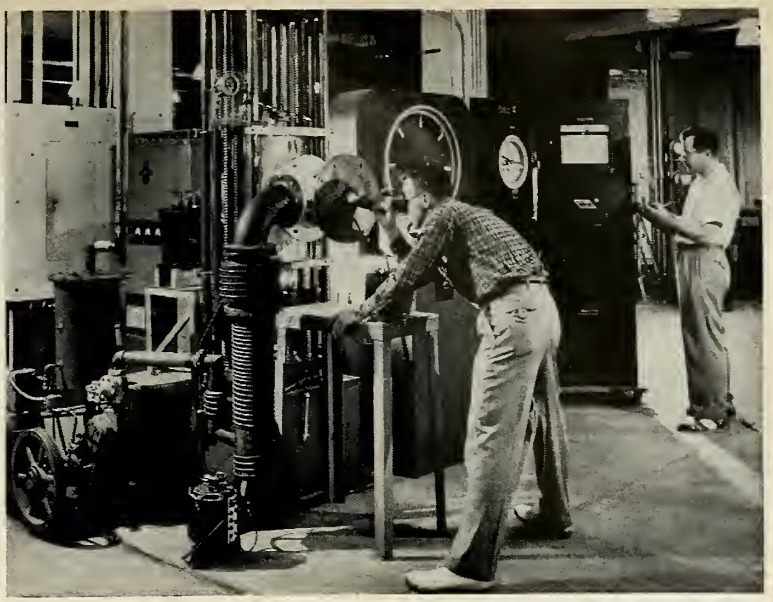
Here, in brief, are the refractory metals' properties:

Be, Ti, V

Beryllium, titanium, and vanadium are not always considered refractory metals since their melting points are somewhat lower than those of the clearly distinguished refractories. However, their melting points are sufficiently high and their properties are similar enough to those of such metals as chromium and molybdenum that they are included in this discussion.

Beryllium is more important as a nuclear fission moderator than as a refractory metal. Until recently its primary metallurgical use was as a hardening agent in copper alloys. Its two outstanding gifts to missiles—low density and high melting point—are offset by its chief fault: beryllium is very brittle at room temperature; it is difficult to work. However, once fabricated, beryllium shows good ductility at high temperatures.

Tonnage quantities of titanium have been available from a number of companies for several years. Titanium, as a raw material, is inexpensive. However, it is so difficult to work that the prices of finished products are too high for many otherwise ideal applications. Titanium alloys give good service in normal air up to about 1200°F. Titanium offers good strength-to-weight ratios up to about 1000°F. The largest present consumer is the aircraft industry.



When the price of vanadium is reduced considerably from its present $80 per pound, it will find wide use as an improved replacement for stainless steel around 1700°F. It has a high melting point, is light in weight and is stable in normal air atmospheres up to about 1250°F. As important as any other feature is the fact that vanadium is easily welded.

Chromium

Chromium offers good resistance to oxidation even at very high temperatures. It maintains structural strength at high temperatures. However, nitrogen dissolved in chromium makes the metal brittle. The nitrogen can be removed on a lab scale, but no process so far is suitable to tonnage production. Chromium's major missile use is in alloys for service at 1800-2000°F. The bluish-tinged, silver-white metal is prepared either by electrolytic reduction of chromic acid in water, or by reduction of chromic oxide with aluminium. Stainless steel contains about 15% chromium.

Zirconium

The zirconium industry is well established, producing tonnage quantities for atomic energy uses. Zircalloys—dilute alloys of zirconium, tin and iron—offer the corrosion resistance needed in pressurized water reactors. Alloys for use at higher temperatures in more corrosive surroundings—as in sodium reactors—are in development stages now.

TENSILE STRENGTH of metals is tested at temperatures as high as 4000°F on this apparatus developed at Lewis lab. Results are applied to production of rockets.

Niobium

Niobium, also called columbium, joins molybdenum and tungsten as the three most important refractory metals. Already it has found wide use as an alloying material for nuclear reactor fuels, and the nation's research effort on the metal is just beginning to pick up momentum. It offers high strength at high temperatures, corrosion resistance, and is easily alloyed with many other metals. Mill-run niobium's properties vary with the production technique. However, research is underway to discover the exact factors and means of controlling them.

Niobium often is compared with molybdenum. Actually, it has certain advantages over molybdenum: lower density and greater resistance to oxidation. However, even niobium oxidizes too readily at extremely high temperatures to be used without protective coatings. It is fine up to around 2500°F.

Molybdenum

Molybdenum has been in wide use and has been produced in tonnage quantities for over a dozen years in the U.S. It is best known for its high melting point and the even higher melting points of some of its alloys. Its drawbacks are brittleness at room temperature and ease of oxidation at high temperatures. The big research problem is development of fool-proof, easy-to-apply anti-oxidation coatings. In the case of niobium, when the protective coating ruptures, the metal's strength fails slowly. However, even a tiny crack in molybdenum's protective coating leads to immediate failure of the piece at high temperatures. This calls for several separate coatings to assure absolute coverage of the surface. Sprayed or plated alternate coats of nickel and chrominum are the best bet.

Tantalum

Niobium and tantalum are sister metals, almost always occurring together in nature. Chemically they are very much alike and are therefore difficult to separate. However, tantalum has a higher melting point and is generally stronger than columbium. Despite high cost, tantalum finds many uses where corrosion is a problem.

Tungsten

Tungsten is by far today's most important refractory metal. A large industry is well established. Its properties are well defined, thanks to many years of research. It has the highest melting point and recrystallization point ("freezing point" if you please) of any metal. Its drawbacks are a high melting point that makes it extremely difficult to work with, its ease of oxidation and room temperature brittleness. Tungsten also has the highest density of any refractory metal. In some cases, this is good, but it's a drawback where weight considerations are important.

SOLARIS Might Salvage Missiles

Its designer, Vitro Laboratories, says the weird-looking undersea device could be used for a wide variety of missions at 'low' cost

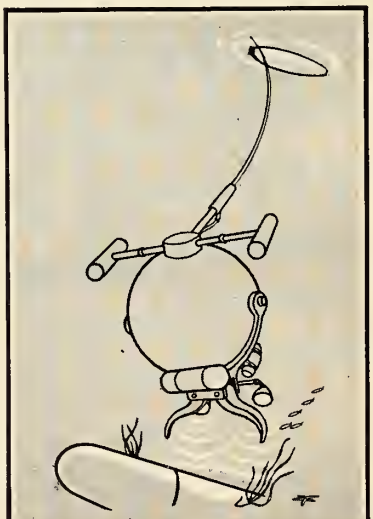
by William E. Howard

WASHINGTON—Like some weird creature of the deep, the ball-shaped "fish" with a mechanical claw bolted to its belly glides silently through the sea. Depth: 1900 feet.

A pair of lights projecting from metal arms pierce the total darkness, illuminating a patch of ocean floor. Positioned between the lights in a pressure case, the unwinking eye of a small television camera stares glassily downward, hunting.

A small squid foraging on the bottom is caught in the light for a moment and quickly scuttles into familiar darkness.

Suddenly the "fish" stops. Twin hydraulically driven propellers mounted on the upper side keep it hovering in the current. Just below, half-buried in the mud, the light plays over the first-stage booster of a big *Saturn* space vehicle.



Slowly, the "fish" descends on the booster; the claw opens and then closes over an engine cluster support ring. At the touch of a switch by a console operator aboard a surface ship, a shipboard winch whines into action and the "fish" holding its catch is reeled in by a steel cable.

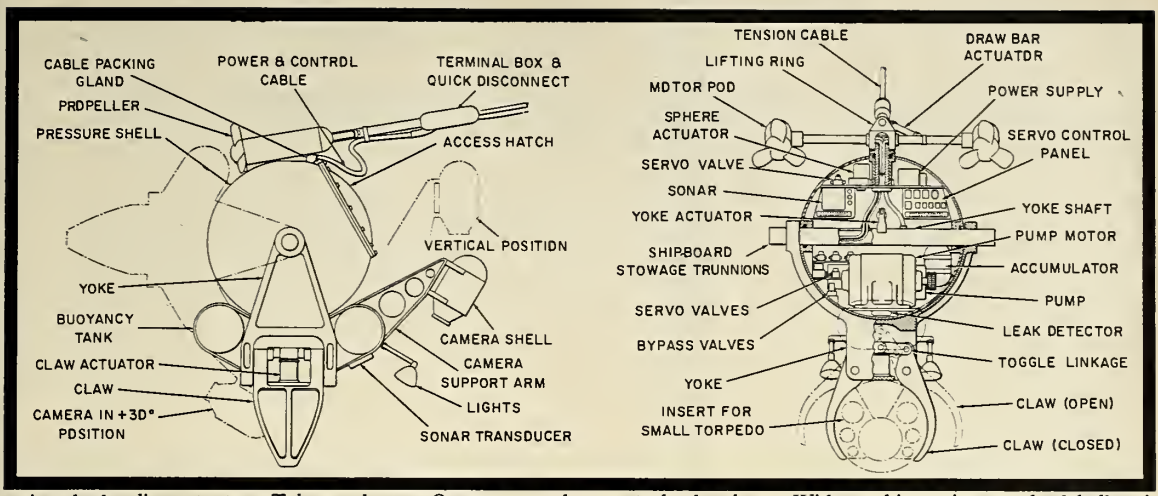
• **Exploration and detection**—Salvaging valuable rocket boosters in this manner is but one of many missile support and undersea applications of the remotely controlled SOLARIS (submerged object locating and retrieving/-identification system) now being developed by **Vitro Laboratories,** Silver Spring, Md., a division of **Vitro Corp. of America.**

The system has a wide range of peaceful, as well as military uses. Ultimately it may be a key to gaining important knowledge about the vast unexplored regions of the sea.

Designed originally by Vitro to retrieve valuable experimental torpedoes and mines being developed for the Navy, more applications are being visualized for SOLARIS every day. Equipped with sonar, it could be used to sweep wide areas of the sea to detect hostile submarines (M/R Aug. 10, p. 24).

The TV "eye" will permit finding and recovery of missile nose cones and underwater cables, and placing and observing the effects of explosive charges. It can inspect ship bottoms, bridge pilings, river channels and bouys; survey and clear harbors of obstacles and assist the work of divers.

SOLARIS retrieving system in operation could recover missile nose cones.



As presently conceived, the system is capable of hauling to the surface loads up to 5000 pounds weight in water. At 1200 feet SOLARIS can search a semicircular area 250,000 yards square—without moving the controlling surface vessel.

The device comes with a number of specialized attachments. One—an over-center toggle action claw—is designed to clamp around cylindrical surfaces, like nose cones of known diameter, without crushing them. Another special claw is intended specifically for cable maintenance. There are special attachments for placing explosive charges and for a stud gun to fix the device to an object. The general purpose claw can grasp a wide variety of objects. Servo control of the actuating cylinder allows varying pressure to be applied.

• **Wire-guided history**—Maker of the *Mark 39* wire-guided torpedo—an ASW weapon—Vitro says SOLARIS is a "logical development" of another (classified) underwater vehicle which it has made for the Navy, which employs a "television camera for positive identification of underwater objects."

Control of SOLARIS is by means of a power cable which pays out along with the steel support cable. The power cable contains two co-axial TV cables, conductors, and signal, control and power leads.

Motive power for the sphere, which is 42″ in diameter, is provided by an electrically powered hydraulic pump. This drives a pair of propellers mounted in pods on the ends of a transverse tube at the top of the sphere. A drawbar, to which the cables are attached, pivots laterally about the center of this tube. It is controlled by a double

acting hydraulic actuator. Tube and drawbar remain at right angles to each other except when steering to the left or right.

The propeller pods rotate individually about the tube in parallel vertical planes, enabling the propellers to thrust upward, down or forward. System stability is obtained by balancing vehicle drag and cable tension against thrust. A slight change in thrust angle is sufficient to move the vehicle slowly in the direction of the unbalanced force component, according to Vitro. And greater changes in thrust angle allow the vehicle to maneuver quickly in any direction. Distance limits are controlled by the winch paying out cable.

• **Sphere detail**—The sphere hangs vertically and is free to rotate about the propulsion and control assembly. Fabricated of 6061-T6 aluminum alloy, the sphere is formed in two hemispheres welded together. It has a 22″ watertight hatch for interior access. Shell thickness is 0.45″ for 2000′ depth.

A 15 horsepower electric motor located in the bottom of the sphere drives a 3000 psi hydraulic pump at a flow rate of 8 gallons per minute. The pump supplies all the mechanical power for propulsion and the control of the vehicle and its accessories. An accumulator provides extra capacity during cylinder actuation. Seven servo valves and an electric by-pass valve control the flow to motors and actuators.

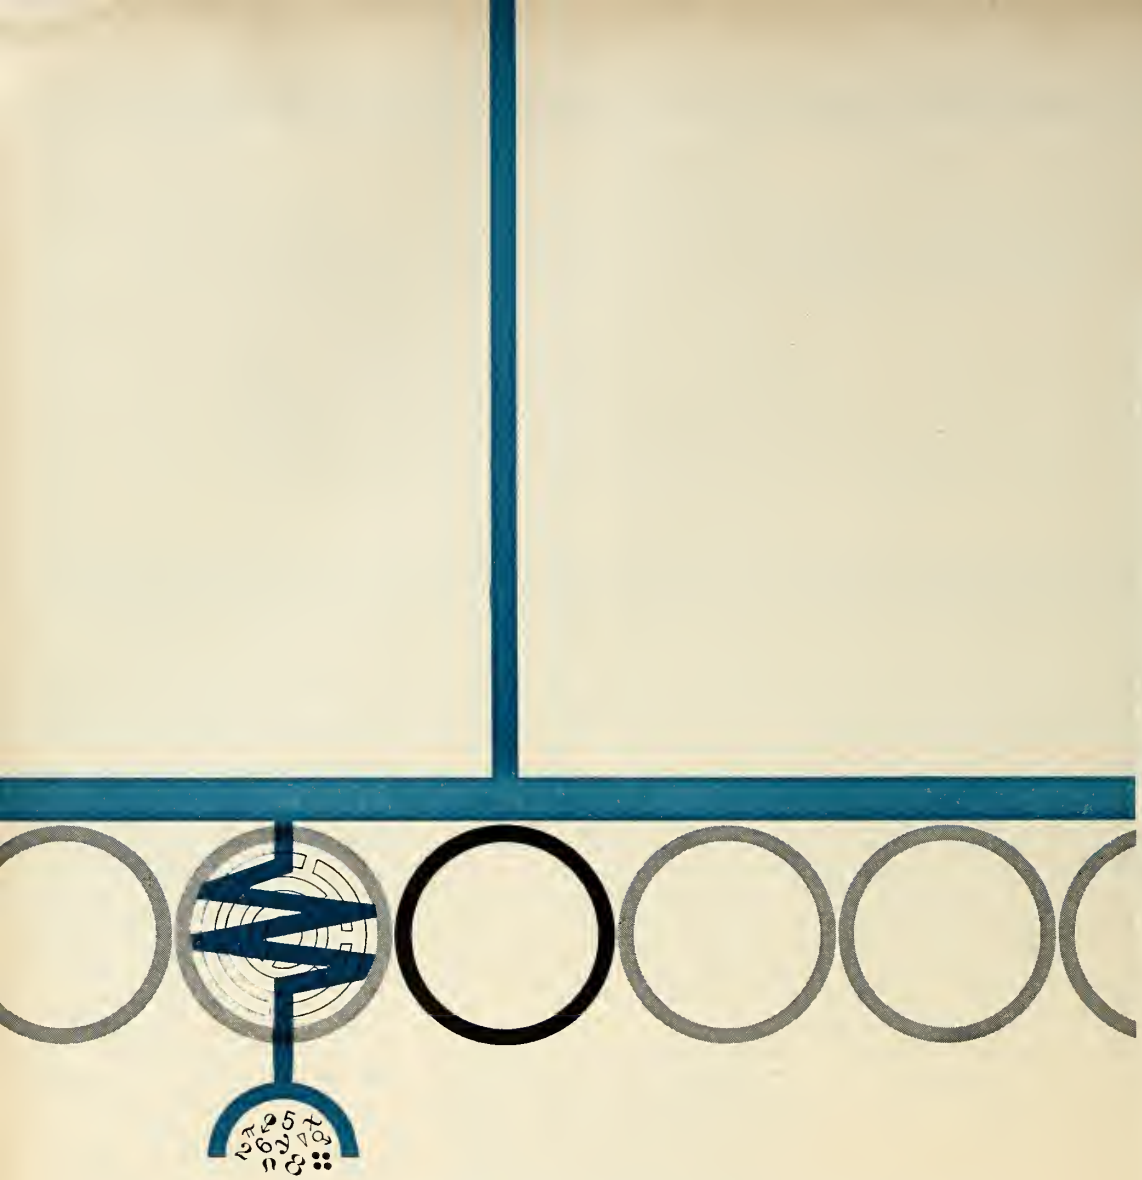
One servo valve controls the flow to propulsion motors, and regulates thrust. The motors use 7 gallons per minute at the maximum of 10 horsepower, leaving 1¾ horsepower available for control actuation. Two servo valves individually control the vertical plane thrust angle of the propellers.

One servo valve controls drawbar angle and, thus, the thrust angle in the lateral plane. Two more servo valves control rotation of the sphere and the pitch angle of the claw accessories and the television camera assembly. A seventh servo is available for actuation of the accessory device. An electric bypass valve frees the attachment positioning actuators after securing the object, insuring that the attachment and its load do not disturb the stability of the vehicle.

In addition, the sphere contains a leak detector and a depth measuring sonar. Built into the sphere is 100 pounds reserve buoyancy for various special equipment which may be added.

VEHICLE retrieving a missile booster engine with its mechanical "claw."

Without this equipment, lead ballast is added to preserve the sphere's 50 pounds net positive buoyancy.



• **Closed circuit TV**—For normal salvage and inspection work, Vitro says a Dage Model 60-BR television camera is satisfactory for depths up to 1200′ further down an image-orthicon camera would be preferable.

Power supply for the camera and 1000-watt diving lamps is located inside the sphere and operates from a 600-volt power line. The camera is mounted in a pressure vessel on a rigid boom attached to the yoke in a position to center its field of view through, and a little below, the jaws of the accessories.

The 400-pound console, measuring 5x3x4½′, displays information on the vehicle's heading, depth, height above bottom, claw azimuth, claw pitch angle, propeller rpm, illuminating current, and time on lights; there is a monitor screen for the closed-circuit television. It also gives information on winch speed, motor current and the amount of cable paid out, as well as temperature, voltage and current of the power supply.

Two hydraulic winches with hydraulic drive handle the power cable and support cable individually. The support cable winch is controlled by the operator and the power cable winch is slaved to it by a constant tension clutch driven a 10% slippage.

In comparison to other systems designed for the same purpose, Vitro says SOLARIS offers greater speed, compactness and versatility. And although the price of one is not disclosed, the company says initial and operating costs for the system are "low."

"NEW DIMENSIONS | in computation for military systems"

The Capital's Top Private Industry

Area's R&D firms double in five years to provide much of the brains for production done elsewhere —last of a series on Middle Atlantic area

by William E. Howard

WASHINGTON—Around the Nation's Capital the saying goes: "You can hardly swing a cat downtown without hitting a Ph.D."

Since it is the pivotal nerve center for the nation's entire defense program, it isn't surprising that the town is aswarm with scientists. Thousands have been uprooted from distant college laboratories and are now working for the government in the great post-*Sputnik* proliferation of missile and space agencies. Hundreds more from industry pass through daily on Pentagon and Capitol Hill missions.

But what does astonish many a blasé Washingtonian is something which has become apparent only recently. Very quietly—and suddenly—the city's metropolitan area has turned into one of the country's major *private* research and development centers. Although it may be small next to the mammoth federal government establishment, nevertheless this missile/space R&D activity is the area's Number One private industry.

Realization of this important new addition to the local economy has come with a just-completed nose count by the Washington Board of Trade, which reports that as of today there are 128 of these enterprises—double the number five years ago. This year alone four new ones have gone into business; last year 17 were added.

These companies have a combined annual sales volume estimated at well over $200 million. They employ 16,000 persons—most of them engineers and scientists. And there are thousands of scientists working for such government agencies around town as the Naval Research Laboratory, Naval Ordnance Laboratory, Naval Weapons plant, Diamond Ordnance Fuze Laboratories, Corps of Engineers Research and Development Laboratories and the National Bureau of Standards.

STARS show areas of concentration of R&D work in the capital and its suburbs.

All this new activity, says the Board of Trade, has made Washington the country's fifth largest scientific community in overall size and "first in the number of scientific and professional personnel per 1000 population."

• **Missile manufacturing**—Proximity to the Pentagon is one main reason for the upswing in private laboratories and highly specialized small companies. But there are other contributing factors, such as a broad scientific community existing in the area's colleges and universities and a wealth of engineering talent that has been attracted by the cultural advantages of a large metropolis.

Moreover, Washington is located in the middle of the lower mid-Atlantic's busy missile manufacturing region extending all the way from Wilmington, Del., to Norfolk, Va. Hundreds of big and small companies scattered along this seaboard section are heavily engaged in missile manufacture. Many of them are working hand-in-hand with Washington R&D firms.

Total missile-related manufacturing for the entire area is estimated at over $1 billion and total employment in the field is well over 100,000.

As some Washington experts point out, the area's R&D firms are providing much of the brains for the production brawn being carried on nearby and elsewhere across the country. A notable instance is the Navy's family *of Tartar, Terrier* and *Talos* shipboard missiles.

The Applied Physics Laboratory of Johns Hopkins University, developer of the anti-aircraft shell proximity fuze, is in charge of the technical direction of the entire program for all three missiles. **Vitro Laboratories,** a division of Vitro Corp. of America, which has a plant not far from APL in Silver Spring, Md., is in charge of systems engineering the three surface-to-air weapons for BuOrd.

A rundown of contractors for *Talos* shows **Allegany Ballistics Laboratory,** Cumberland, Md., prime for propulsion design, development and pilot production; Naval Ordnance Laboratory prime for warhead design; launchers made by the Naval Weapons plant; fuze by **Melpar Inc.,** Falls Church, Va.; warhead fabrication by the **ERCO Division, ACF Industries,** Riverdale, Md.; and boosters by the Naval Propellant Plant, Indian Head, Md. NOL and the Naval Weapons plant also are providing warhead design and launchers for *Terrier* and *Tartar.*

• **Martin's** *Mace*—Biggest concentration of missile manufacturing in the area is at Baltimore, where **The Martin Co.** is prime contracting the Tactical Air Command's surface-to-surface *Mace.* The Baltimore operation is also supporting **Martin-Orlando** in the production of *Bullpup* and *Lacrosse* and the *Titan* ICBM program at Denver.

Following Navy cancellation Aug. 22 of its Seamaster contract, with a layoff of 3000 employes, most of Martin's 14,000 employes now are working on missiles. Baltimore division missile sales are running at $500 million a year with a payroll of $56 million.

Martin leads area contractors . . .

Martin has hundreds of subcontractors nearby. The Naval Propellant Plant provides propellant loading for Martin's air-to-surface Navy *Bullpup*. *Bullpup* power supply is being made by **Catalyst Research Corp.**, Baltimore. In Virginia, the Navy Proving Ground at Dahlgren developed the missile's warhead design and the naval Weapons Station at Yorktown is loading the high-explosive warhead.

At Baltimore's Friendship Airport, **Westinghouse Electric Corp.'s** Air Arm and Electronics Divisions and Ordnance Division, Lansdowne, employ around 6000 persons in production of missile guidance and control systems and in development of underwater missiles, including the Navy's nuclear-tipped *Astor* torpedo. The Air Arm is principal subcontractor for the Air Force *Bomarc* homing radar flight control.

• **Delaware's duPont**—Much of the basic material, like Teflon, and chemicals which go into the production of components for today's advanced missile and space systems is produced at the huge **E. I. duPont de Nemours** plant in Wilmington. The company has a large campus-style research headquarters where hundreds of scientists are conducting basic research into "exotic" new compounds.

Another big employer in Wilmington is **Hercules Powder Co.**, which has a NASA contract to produce third and fourth stages for the solid-propelled *Scout* space vehicle. The company also is working on propulsion for the solid-fueled **Boeing** *Minuteman* ICBM.

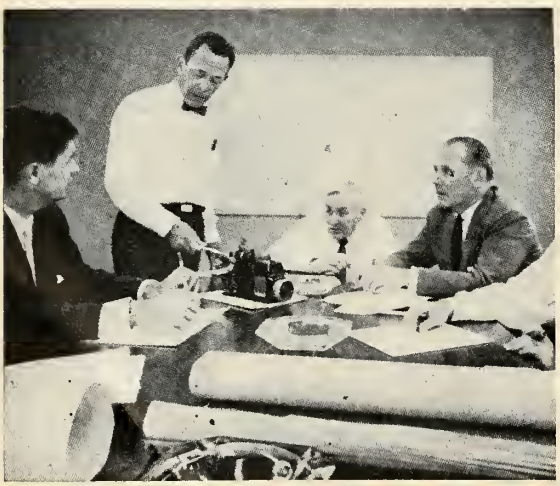
Hercules in addition runs the Radford Arsenal, Radford, Va., which makes JATOS for *Nike-Hercules* and motors for the Army's *Honest John* and *Little John*.

• **From $15 to $29**—Typical in some ways, but highly unusual in others, is the story of **Atlantic Research Corp.**, just across the Potomac from Washington in Alexandria, Va. In 1949, Arch Scurlock and Arthur Sloan left the Office of Naval Research and with $1000 capital opened a laboratory in a warehouse.

Now, a decade later, they have more than 600 employes and contracts running into the millions on a score of highly complex missile/space projects. ARC is one of the leaders in solid-propellant rocketry and is the builder of the *Arcas* atmospheric sounding rocket. On June 30, just before the opening of a new $1 million building, ARC made a public offering of 100,000 shares of stock. Space-conscious local investors quickly snapped it up at $15 a share and drove the price the same day to $29. It is now selling for $34.

Five years ago two former Bureau of Standards scientists sold **Emerson Radio & Phonograph** on starting a research laboratory. Today Emerson Research Laboratories in Silver Spring, Md., is making the target detection device for the Navy's *Corvus*. It has nearly 400 employes and a $4 million-a-year operation.

Vitro Laboratories, which is hard at work in the anti-submarine warfare area, expects sales to hit $7 million this year—up 10% from last year—and now has nearly 700 employes.



Melpar Inc. is the Washington area's biggest private employer—with 5000 skilled technicians and scientists making electronic equipment. Its products go into *Talos*, *Atlas* and *Jupiter* missiles in addition to space vehicles.

Other suburban Maryland R&D companies which are growing rapidly include **Washington Technological Associates,** which is developing the automatic strikedown and mating system for *Talos*, and **Systems Planning and Research Corp.**—in the same building—which is developing an advanced range instrumentation system for the White Sands Army Missile Range. There are others like **Airtronic Inc., Advanced Research Associates Inc., American Instrument, Andromeda Inc.,** and **Robinow Engineering.**

Applied Physics Laboratory was founded by Johns Hopkins during World War II and succeeded within two years—from late 1940 until late 1942—in developing the antiaircraft proximity fuse. It now has 1300 employes—525 of them engineers and scientists.

Right in the District of Columbia there are many more. **Page Communications Inc.**, a subsidiary of **Northrop Corp.**, has just won a $10 million contract for a 1700-mile troposcatter Air Force communications complex in western Europe. **Wellings-Reed Inc.**, is working on astronautic systems and missiles and **Spacetronics Inc.** is designing spacecraft and air cushion vehicles.

• **And Richmond, too**—Much of the recent dramatic growth in missile/space R&D has taken place in Virginia. While a large portion of the new industry has tended to congregate in Fairfax County and Alexandria within sight of

EXPERTS AT Washington Technological Associates—one member of area's R&D community—work on missile support.

TWO OF the Nation's guided missile cruisers, USS Boston and USS Canberra, side by side at Norfolk Navy shipyard.

the Pentagon, many more firms are spreading out across the state.

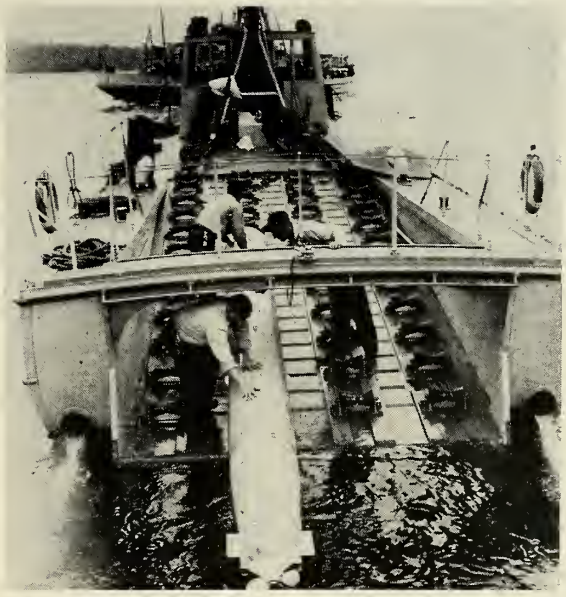
A survey by the State Division of Industrial Development shows that Fairfax County (Melpar, Atlantic Research, etc.) is the state's leading missile and electronics center with a total of 15 firms in the field. Other centers—chiefly in electronics—are Norfolk, Richmond, Lynchburg, Roanoke and Charlottesville.

General Electric Co. has plants in Lynchburg, Roanoke and Waynesboro. The company employes 1000 in communications equipment production at Lynchburg, which is tied in with GE-Syracuse, N.Y., on troposcatter systems.

At Richmond one of the big missile age employers is **Reynolds Metals Co.,** with 1400. The company produces aluminum extrusions and a sheet aluminum foil laminate with duPont "Mylar" film which was used to make the 12-foot inflatable satellite which NASA tried unsuccessfully to orbit earlier this month. Another is **Robertshaw-Fulton Controls,** with annual sales running at the rate of $80 million.

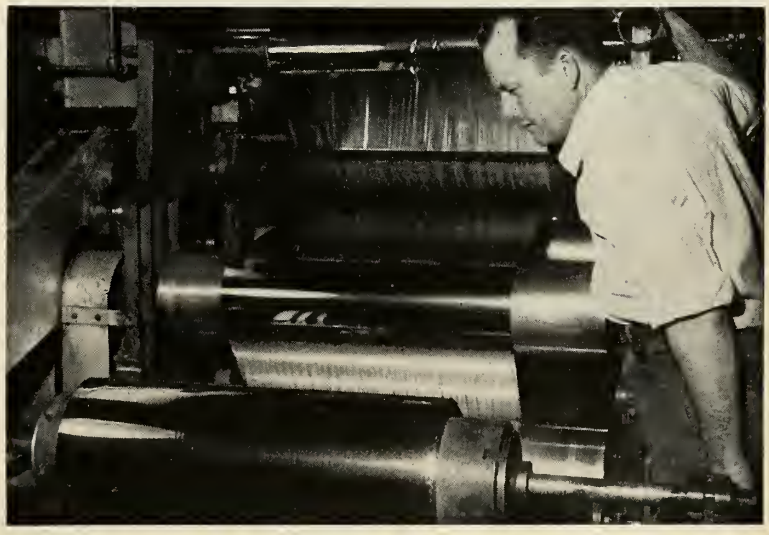
Experiment Inc., recently acquired by **Texaco,** has been designing ramjet engines since 1945. It built and flight tested the first monopropellant ram-rocket propulsion system in 1954. Today it has about 110 employes and a missile R&D sales volume of approximately $1.3 million. Producing missile tracking photographic equipment is **Flight Research Inc.,** with 50 employes.

Dominating the Virginia defense installation picture is Norfolk—home of the biggest concentration of naval power in the world. At the **Newport News Shipbuilding and Dry Dock Co.** four fleet ballistic missile *Polaris* submarines are being built. The yard on July 1 was awarded a $63 million contract for two of the subs of the Ethan Allen class.



At the naval shipyard, warships are undergoing conversion to missiles. Some 35,000 civilians are employed by the Navy at Norfolk and the city is home base for 100,000 men of the Atlantic fleet and another 50,000 on shore duty. This year the Navy will spend about $800 million in maintaining its Norfolk facility.

Included in this amount will be the operation of the Navy Missile School at Dam Neck just outside of Norfolk where seamen and officers are learning how to shoot *Polaris, Talos* and other birds.



Topping off the state's new-found role in the Space Age are NASA's high-altitude experimentation station at Wallops Island, and Langley Field—where the nation's first astronauts are in training for a ride in the *Mercury* space capsule.

ACROSS Potomac River in Alexandria, Va., is new $1 million building of the Atlantic Research Corp., which doubles in research work and *Arcas* rocket production.

U.S. NAVY retriever recovers an *ASTOR* torpedo, in development by Westinghouse Ordnance Division, Lansdowne, Maryland.

ALUMINUM foil and plastic skin for the 12-foot inflatable satellite which NASA tried unsuccessfully to orbit this month was produced by Reynolds Metals, Richmond.

The Case for Manned Lunar Flight

NASA officials, speaking for themselves, argue that man can accomplish more than instruments and outline plans for flight direct to moon

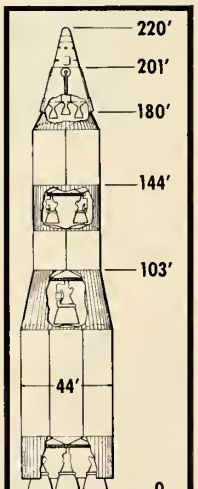
LONDON—Two NASA scientists are taking exception to the general scientific philosophy that early lunar exploration should be undertaken by instruments rather than man.

In a paper to be delivered at the 10th annual Congress of the International Astronautical Federation which opens here this week, the scientists—M. W. Rosen and F. C. Schwenk—contend that it is historically and economically unsound to limit early exploration to instrument probes. And—they say—it will be immeasurably more expensive to attempt to duplicate with instruments what could be accomplished by a few men on the moon.

Taking note that their opinions are their own and not necessarily those of NASA, Rosen and Schwenk say the importance of the simple data that instruments can collect is unjustifiably magnified. In addition, they argue, there are millions of things that instruments cannot do. They point out that no combination of mechanical or electronic devices exists that can duplicate the sensing capabilities of man—nor replace his ability to record, remember, interpret and discriminate.

Rosen and Schwenk advocate a direct flight vehicle as the most likely approach. They say an orbital rendezvous program involves accumulating in an earth orbit the required hardware and fuel for escape, landing on the moon and return to earth. While a smaller booster is required for the orbital rendezvous method, the program offers some disadvantages, they say, including the need to perfect rendezvous techniques, man the orbital station, build an equatorial launch site, and produce a number of space vehicles for one mission.

• **Design factors**—A 2½-day flight was proposed for the manned mission. The first three stages would accelerate the payload and remaining stages to an inertial velocity of 36,000 feet per second. After coasting to the vicinity of the moon, the fourth stage would lower the remainder of the vehicle to a landing. At departure, the fifth stage would propel the vehicle toward the earth, and after 2½ days, the payload would approach our planet. A sixth stage of propulsion could be used to slow the capsule to orbital speed, or the vehicle could enter the atmosphere at hyperbolic velocity.



• **Propellants**—A major concern is the selection of propellants for the various stages. High-energy propellants—liquid oxygen and hydrogen—were cited as the most desirable to achieve the mission with the least vehicle gross weight. Rosen and Schwenk add, however, that this propellant combination can be used only if the necessary engines are available and the techniques for handling liquid hydrogen are developed.

For a return capsule weight of between 8000 and 9000 pounds, the vehicle at lift-off must weigh more than 4 million pounds. A sea-level thrust rating of over 6 million pounds is required. NASA is developing an engine capable of producing 1.5 million pounds of thrust with liquid oxygen and kerosene propellants. A cluster of several of these engines was cited as a logical choice for first-stage propulsion.

A hyperbolic velocity re-entry is assumed. A powered sixth stage could be employed to first slow the vehicle to orbital speed; thereupon the landing would be similar to that of NASA's Project *Mercury*. However, retro-to-orbit is a costly maneuver and its use would require a vehicle so large as to make the task of a manned lunar landing too ponderous unless nuclear or electrical propulsion schemes are considered.

• **Vehicle characteristics**—The outline drawing of a typical direct-flight vehicle shows that it stands about 220 feet high and the first stage is 48 feet in diameter. The conical portion at

AT LEFT, crewman sets out to explore the moon from the proposed direct flight vehicle, remaining stages of which will be used for return. At right, drawing of vehicle.

the top contains the landing or fourth stage, the take-off or fifth stage, and the manned capsule or payload. Upon return to the earth, the payload will weigh 8000 pounds including men, equipment, capsule, guidance and control, and parachute. Two or three men will constitute the crew.

Six engines, each of 1.5 million pounds of thrust, power the first stage. Liquid oxygen and kerosene are carried in a cluster of seven tanks, each one 16 feet in diameter. One altitude version of the 1.5 million-pound-thrust engine propels the second stage. This stage uses a cluster of four 16-foot-diameter tanks. The high-energy third stage also consists of a cluster of four of these 16-foot tanks and a thrust level of 600,000 pounds is produced by four engines.

The fourth, or landing stage utilizes high-energy propellants with throttleable engines to provide variations of thrust for the landing maneuver. The landing stage must be able to hover while the pilot makes his final choice of a landing spot. Approximately one minute of maneuvering or hovering time is provided. Retracted landing legs appear on the side of the fourth stage. When extended for landing, the legs span a distance of 40 feet for purposes of stability.

The fifth stage is placed in a cylindrical tube that pierces the tankage of the landing stage. At take-off from the moon, the fifth stage slides out of the landing vehicle on rollers. This arrangement was chosen because it presents a vehicle with a low center of gravity, reducing any tendency for the vehicle to topple on the surface of the moon. In addition, the propellant tanks of the spent landing stage which surround the fifth stage serve as meteor bumpers and shielding against thermal radiation. Furthermore, no landing loads are transmitted through the return stage, thus minimizing the danger of a rough landing.

• **Two-story capsule**—The manned capsule is an enlarged version of the one used in Project *Mercury*. It is a truncated cone, with a maximum diameter of 12 feet and a height of 14 feet. Inside the capsule, two levels are provided. The lower level contains contoured couches for the crew, controls, communications, and a folding air-lock for use on the moon. The upper level contains food, power supply, exploration gear, and work space.

The outer surface of the capsule is covered with ablative material for insulation against and removal of heat generated during atmospheric re-entry.

• **Guidance systems**—Guidance requirements normally are divided into three phases: initial, mid-course, and terminal. For this mission, these three functions must be provided for both the moon-bound and the earth-bound trips. In addition, the pilot's capabilities in performing major guidance tasks or in monitoring an automatic system are considered. An unmanned return vehicle—a spare—should be placed on the moon prior to the manned flights to provide an escape route should the manned vehicle be damaged upon landing.

The initial guidance phase from launch to earth-escape can be accomplished with sufficient accuracy by inertial systems now under development. Mid-course guidance by means of earth-based radio can direct the vehicle to an accuracy of 50 miles for a lunar impact trajectory. The terminal phase involves the final approach to the moon and the luncar-landing. These maneuvers require vehicle-contained guidance; however, lunar-based radio beacons will assist.

A combination radar-optical system will sense altitude and velocity components relative to the lunar surface. In all but the initial guidance phase (during launching), the pilot can effectively monitor and override the automatic system if necessary. During the mid-course phase, in particular, he can make optical observations of the lunar disk for distance and path angle measurements. The pilot will also be very effective in the final phase of the landing on the moon.

Launching from the surface of the moon will be guided by an inertial system that is aligned and calibrated by the pilot on optical sightings of stars and earth. The proper re-entry corridor in the atmosphere is reached by a combination of optical sightings from the vehicle and earth-based radio signals. During re-entry the lift of the capsule is utilized to modify the trajectory so that the vehicle follows a prescribed deceleration program and lands within the recovery area. The first phase of the re-entry maneuver will utilize vehicle-contained guidance monitored from the earth. After the initial slow down to orbital speeds, earth-based radar in the landing area will control the vehicle.

The mission described is based on a preliminary design study of the type conducted by many agencies to assess the feasibility of a vehicle design. All of the engines are either being developed or programmed for development in the next few years.

PROJECTED mission would include (bottom to top): launching from earth; third stage firing; approach to moon (under jet control), and fifth stage takeoff from moon.

Proceed- OPERATION EXPANSION

September 1, 1959 — Raytheon Government Equipment Division today announced a major expansion into five operating subdivisions: Submarine Signal, Airborne Electronic, Systems Management, Heavy Electronic, and Santa Barbara.

Made necessary by expanding product activity, the decentralization has created managerial and technical staff positions in all areas.

Engineers and scientists of established technical competence are invited to investigate the several opportunities present in the area encompassing their particular interest.

Inquiries should be forwarded to Mr. Donald Sweet, Engineering and Executive Placement, Government Equipment Division, Raytheon Company, 624C Worcester Road, Framingham, Mass.

Emerson's Prolific E&A Division

Company compiles an enviable record in missile work and comes up with startling developments for the future while bucking 'decentralization' trend

by Charles D. LaFond

ST. LOUIS—Controlled diversification, scientific and technical initiative, production competence, bold product development, capable management, continued growth—these are attributes without which today's manufacturer surely will die.

Typical of those medium-sized firms which have survived business uncertainties is the **Emerson Electric Manufacturing Company.** A 69-year-old electrical manufacturer, it not only has survived but has enjoyed steady conservative growth and parallel prosperity.

Maintaining roughly a 3:2 ratio of commercial-to-defense sales, the Company is a strong arm for the missile industry—and it is strengthening its position steadily. Some startling developments have been achieved through the efforts of its Electronics and Avionics Division, and some of those recently revealed should serve as a catalyst to speed its ascent.

For example, one recent development by the division could revolutionize missile and space-vehicle cooling. Called Thermolag, this paint-like substance, utilizing the principle of sublimation, may provide nose cone reentry protection cheaply and more efficiently than an ablation material.

Total sales by the corporation—both defense and commercial—have doubled in the last five years. This fiscal year (ending Sept. 30, 1959) sales are estimated to reach $90 million. Present backlog in defense orders alone is $35 million. Emerson's president, W. R. Persons, anticipates sizeable business expansion in the forthcoming year with the E&A Div. accounting for from 40-45% of total corporate gross sales of well over $100 million. Sales this year in the division will represent 36% of total sales.

Development and production facilities of the division were expanded and modernized in 1958 and 1959. This included completion of a new environmental test facility at the St. Louis plant. Employing between 2700 and 2800 personnel, the E&A division is steadily improving its production work-to-R&D ratio. According to division general manager, C. G. Gulledge, most of the R&D work is now with government-financed cost-plus-fixed fee or cost-plus-incentive fee contracts; company-sponsored work represents approximately 28% of the total R&D effort.

• **Management and operations**—In contrast to the "decentralizing" trend in industry so popular just a short time ago, Emerson maintains a strongly centralized management structure.

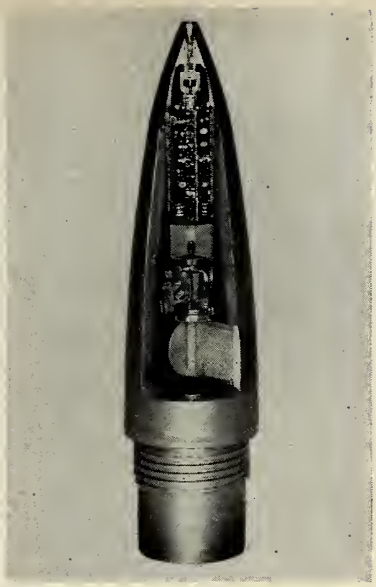
This is the result of a company philosophy that recognizes the need for long-range planning for its research, development and production. This emphasis, demanded by its board of directors and implemented by each key manager and supervisor down the "chain of command," is intended to provide a tight but realistic control of all operations and budgets. Emerson believes it also permits the most efficient use of manpower and facilities.

To further implement the best possible performance and return, whether under contract or company-sponsored,

an intermediate staff level monitors each project.

Monitors control several projects. They exert managerial control over the various project leaders, watch workload and expenditures, serve as consultants, and provide knowledgeable liaison between projects and division general manager.

Emerson's E&A Div. maintains a sizable operations-research group. Its studies provide top management with long-range technical recommendations that could not be obtained any other way—that is, without a crystal ball.



The application of the "scientific method" to help guide executive decision is a costly tool, but its benefits can be far-reaching. Years often can be saved when management has reasonable assurance that each of the roads it is taking is correct and that the pot of gold at the end of each road justifies the journey.

Needless to say, the government also has found such groups indispensable for its long-range defense planning. Because of this need, the E&A operations-research group is not a luxury item—it pays its own way.

Much of the division's efforts in missilery is by now well known. A great deal still is veiled by DOD security classification.

• **The past and present**—The division's success in missile development has been notable. In January, 1954, Emerson was awarded one of two prime production contracts by U.S. Army Ordnance for the complete *M31 Honest John* artillery rocket. Quantity deliveries were made on schedule in August 1954, to the Army's Redstone Arsenal.

In September, 1956, the company was awarded the task of design, development, and fabrication of the motor metal parts and certain airframe components for the *XM50* improved *Honest John* rocket. A letter of commendation from Redstone followed the successful completion of all subsequent tasks.

EMERSON-developed 2.75-inch warhead contains radar-initiated command fuze.

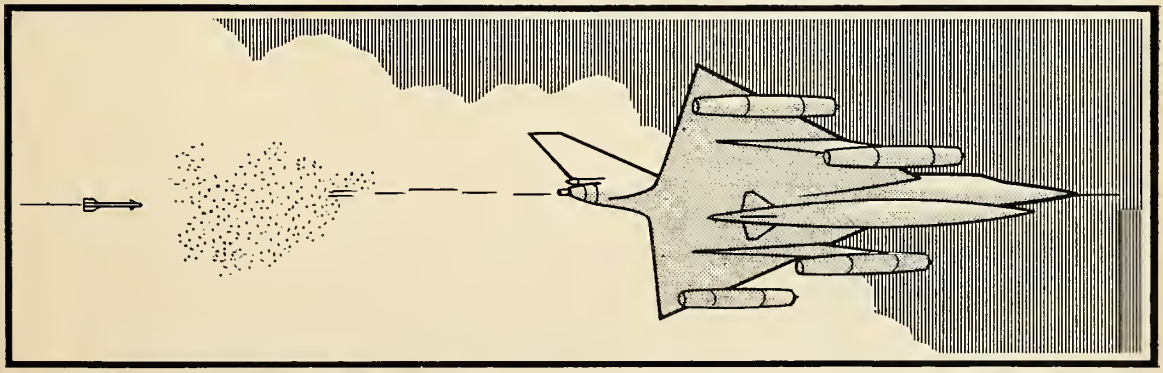
Last July, a $300,000 contract was received to perform a preproduction engineering and ordnance support study for the complete new *XM50* rocket.

Emerson is also prime contractor to the Army Rocket and Guided Missile Agency at Huntsville for development and production of the *Little John* 10-mile range artillery rocket. In support of this program, a 14-man crew of Emerson technicians is stationed at White Sands Missile Range.

For the Navy, Emerson produced the Mark 108 rocket launcher and performed the design study for the *Terrier* launching system for cruisers.

Additional missile work includes subcontracts to the following: **Thiokol**—for *Pershing, Project Able, Minuteman,* and *Falcon* motor cases; **McDonnell Aircraft**—for *Green Quail* decoy missile umbilical linkage.

Considerable advancements have been made by the division in miniaturizing electronics for ordnance and special ammunition. To provide a simple, inexpensive and reliable proximity scoring system, a subminiature microwave receiver was developed for 20-millimeter projectiles. Included also were an electronic firing circuit, electrical primer, safety and arming mechanism, and spotting charge.



A microwave transmitter in the target directs a signal which triggers the projectiles when they enter a coplanar field perpendicular to the projectile path. Thus, firing error and dispersion can be photographically recorded for subsequent analysis.

A radar-initiated command fuse for the 2.75″ FFAR warhead permits accurate timing of operation, and hence, accurate evaluation of the fire control system. Rounds, fired in a cluster, may be selectively exploded. Out of this development, a nose-located receiving antenna evolved that is capable of receiving energy 180° from the course of a rocket.

Based on its long experience with fuzing and small caliber ammunition, including many types and sizes of fragmenting ordnance, Emerson is presently engaged in a highly classified study program for bomber missile defense. A principal problem, it can be assumed, is how to damage the sensitive guidance systems in anti-aircraft missiles most efficiently and with the highest kill probability.

• **The present and future**—As a result of the research performed by the E&A Div., new methods in missile cooling and radical concepts in long range warfare may be initiated.

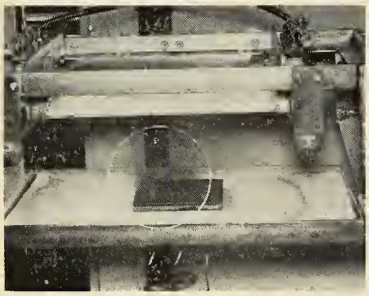
• Thermolag—Thermolag, mentioned earlier, was developed for use as a heat dissipator for hypervelocity flights and has been extremely successful. Mixed and applied like a paint, the substance sublimates (vaporizes directly

M/R artist's concept of a possible antiaircraft missile defense employing small-particle, high-velocity fragmentation.

from the solid state) at a constant rate. Because the temperature of sublimation is not a function of the rate or quantity of heat input, it appears to be superior to ablative processes currently in use on some missile nose cones.

In addition, Thermolag can be conveniently applied on any contour. It cures at room temperature, bonds well to properly cleaned surfaces, and resists metal corrosion. Its vapors are non-toxic. But its greatest virtues are producibility and control. By varying the constituents of the mixture and the application thickness, the sublimation temperature and total vaporizing time can be altered and predicted with relatively good accuracy (within about 100°C).

Lockheed Missiles and Space Division, Thiokol Chemical Corp., the Army Ballistic Missile Agency, and National Aeronautics and Space Administration all have tentative missile or aircraft applications for the material.



The commercial applications of Thermolag could be tremendous.

• Penetration aids—The E&A group's work involving strategic bomber aircraft has been accompanied by intensive investigations for improving their survivability. Continuing and thorough review and evaluation of new concepts, systems and techniques against the backdrop of mission requirements has established a need—at least for some years to come—for manned strategic aircraft.

With world technological growth, penetration vehicle survival strategies and techniques are continually changing. In general, initial advantage is attained with a new and radically different offense which normally assures a vital time advantage. As the new weapon's capabilities become understood by the enemy and countermeasures are developed, the penetration assistance required to insure mission success changes.

Engineering of a special weapons technique, employing long-range radar, shows great promise. The advantages and disadvantages of infrared techniques—and the problems associated with an environment dominated by nuclear ordnance—have generated unique systems requirements which are undergoing detailed analysis at Emerson.

• Anti-submarine warfare—In another area, the search for improved and higher-power sound sources for certain sonar problems, Emerson physicists are studying devices of a unique, non-linear type sound source which indicate considerable improvement over conventional sources of the same class. Laboratory experiments are in progress to investigate details of the phenomena so that design refinements can be achieved. Additional details are highly classified, but the program has been funded by the Navy's Bureau of Aeronautics for over a year.

THERMOLAG sublimation in process employing heat from 26,000-watt infrared heat facility.

APPLICATION of Thermolag demonstrates simplicity of operation. Vapors are non-toxic.

Process Promises To Raise Transistor Limits

MENLO PARK, CALIF.—A new process has been developed here for preparation of high-temperature semiconductors, according to **Stanford Research Institute,** producing high-purity, single crystals of silicon carbide, and promising to raise transistor and diode operation limits from 400°F to about 1800°F.

Two years ago, Nobel laureate William Shockley theorized that silicon carbide crystals might be grown from solution in alloy melts. SRI put his theory into practice under a subcontract from the Navy's Bureau of Ships and the **Shockley Transistor Corporation.**

By modifying a standard crystal-pulling furnace, pure silicon is melted in a carbon receptacle. The carbon of the crucible diffuses into the molten silicon and saturates the solution. A "cool spot" is produced in one area by controlled temperature. A localized area of supersaturated solution results from which the crystals can be grown.

ASTRONAUTICS DIVISION FORMED AT VOUGHT

Broader responsibilities in the Space Age. Full utilization of existing and rapidly expanding technological capabilities. These are the objectives of Chance Vought's newly formed Astronautics Division. Missile men for 12 years, this seasoned group is concentrating on advanced concepts for exit from the atmosphere, space exploration and re-entry.

Integration of the four-stage *Scout* research vehicle is proceeding under this division's direction. Vought is readying this space rocket and its launcher under a National Aeronautics and Space Administration contract.

Membership on the Boeing team participating in development of *Dyna-Soar* has further sharpened Vought's space capability. This USAF project is intended to create a hypersonic, boost-glide vehicle which will operate at the fringes of the earth's envelope.

For 42 years, Vought has helped solve human factors riddles in atmospheric flight. The company pioneered in compact, high-density cockpits and in pilot escape devices. Today, the company is performing much the same service for space pilots. In Vought's orbital flight navigation simulator, spacemen-to-be are flying by the rules of space, using instruments early space navigators may well employ.

Space is the specialty of Chance Vought's Astronautics Division. Other major interests are being aggressively advanced in the Aeronautics Division — where attention is on atmospheric missiles, antisubmarine apparatus and piloted aircraft — and in the company's Electronics, Research, and Range Systems Divisions.

CHANCE VOUGHT DALLAS, TEXAS

SPACE WILL HAVE ITS ACES

Cadets at the Air Force Academy use a loose-leaf textbook on space. In it goes up-to-the-minute knowledge on research rockets and satellites. Soon the book will include accounts of manned vehicles for upper atmosphere, orbital and space flights. In early flights man and his vehicle will descend to earth by parachute. Next, pilots will return by controlled, glider-like landings. One day, true space cruisers will explore our solar system. The cadet has a vital role in these forthcoming pages for the book on space. He has an exciting place in manned research vehicles . . . a tremendous future in space!

RCA System To Ease Interference

CAPE CANAVERAL—A new spectrum surveillance system recently installed at the Atlantic Missile Range promises to alleviate some of the interference problems plaguing the missile complex. The system was designed by **RCA Service Co.**

Silencing of electromagnetic interference was recognized early as an involvement of the complexities of missile launching, tracking and controlling. The role of an electromagnetic control function was settled in 1950 by the establishment of an Interference Control Office as a major activity of the Air Force Missile Test Center here.

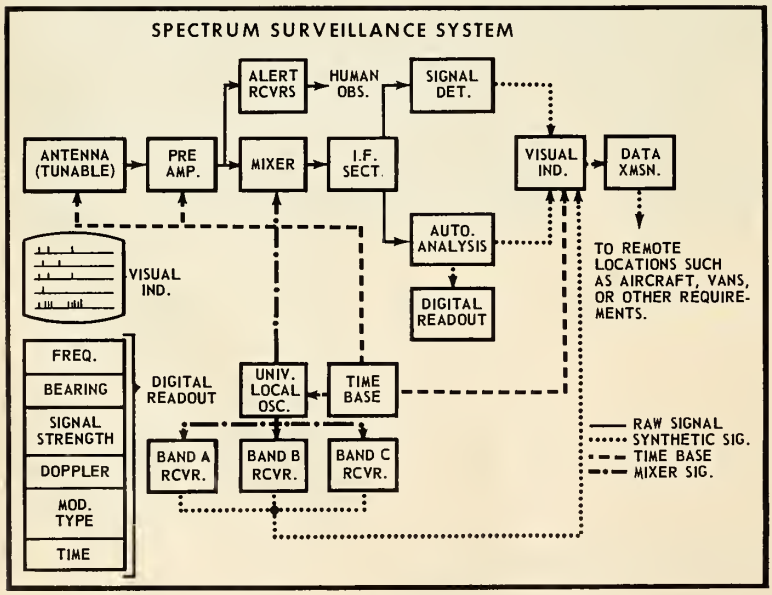
When the scope of electromagnetic control changed and system capabilities increased, Interference Control was expanded and became Frequency Control and Analysis. Not only was suppression of interfering signals required, but analysis and control of all range operating frequencies became a major problem.

By 1959, a new spectrum surveillance system, designed on functional concepts through exploratory engineering, was needed. In June, a rudimentary system with automatic search capabilities was implemented for the frequency range from 50 to 1000 megacycles. The system provides frequency measurement, signal strength measurement, direction finding and a detection threshold of –120 dbm.

TYPICAL spectrum conditions at the Atlantic Missile Range.

• **Versatile system**—Each antenna, a modified version of a discone, is connected to an individual octave of preamplifiers. Using high-gain, low-noise preamplifiers, it is possible to multicouple various signal sources and receivers on each band (octave) without loss of system performance.

Tunable receivers are used with signal analysis equipment to determine the type and modulation characteristics of received signals. Conversely, injection of signal or power standards, at the multicoupler, results in simplified frequency and signal strength measurements.



The converter will accept either a sweeping signal or a fixed signal. In the sweep mode, the system can "observe" any part or all of the band on which it is employed. By insertion of a fixed signal generated from a precision frequency source, the system can be converted to a secondary frequency standard when multicoupled to a frequency stable receiver, such as the 51J or R-390A.

• **Continuous recording**—In the sweep mode, the variable bandwidth receiver provides information for panoramic display of specific signals and alarm circuits. The alarm circuits can either alert operating personnel to a signal intercept or stop the sweep oscillator and start recorders. Other variations and combinations are possible. The alarm circuits are invaluable for detecting and recording intermittent or keyed transmissions. All signals present on any band are continuously recorded. A 17-inch monitor oscillograph provides real time presentation of all signals for visual observation.

Coarse position of the radiation source is obtained by comparing signal intensities from individual antennas "receiving" different sectors. When reception from a given sector is expected, the antennas are oriented for maximum signal. Four such antennas, searching different sectors, form a two-baseline interferometer antenna system. In operation this system is similar to Minitrack. Accuracies of 5° are achieved. This will be improved to 2 or 3 mils when suitable phase measurement equipment is installed.

The system is designed to accomplish the intercept and rapid readout of radiation characteristics by use of high-gain, electronically sweeping, tunable antennas in synchronism with the universal local oscillator. The oscillator provides a mixer signal which permits each receiver to scan a band while all maintain a known relationship to each other. Spectrum density indications and signal search capabilities cover the spectrum from 20 mc to 10 kmc.

The time base which is the syn-

SYSTEM designed by RCA provides a detection threshold of –120 dbm.

chronizer of the system activates frequency shifting in the universal local oscillator, provides timed oscillograph traces, and feeds the frequency tunable antennas to provide azimuth and elevation data.

The received signals are fed through the IF section to the automatic analysis equipment which will indicate "modulation type."

• **Maximum sensitivity**—The signal detector provides the maximum sensitivity possible to establish the presence of a signal. It also provides a shaped pulse for visual indication. The alert receivers provide the capability of signal observation by operating personnel for fine analysis or manual data recording. In automatic analysis, the characteristics of radiations will be read out in digital form for simplified observation, identification and recording.

The facility at the Atlantic Missile Range was developed and installed in less than two months, using off-the-shelf components. It was implemented to evaluate parameters for future frequency control and analysis programming but has simultaneously provided immediate support for various programs at AMR.

Battery Maker's Report Clobbers Hot-Gas APS's

by Charles D. LaFond

DENVER—" . . . the status of Hot Gas APS System for the ICBM programs was such that the failure of at least one out of every ten operational missiles, if required to perform, was practically guaranteed due to the Hot Gas-APS System alone."

In essence, this statement helped to precipitate the recent cancellation of hot-gas APS programs at **Sundstrand** and **Aerojet-General** for the *Atlas* and *Titan* ICBM's according to the **Frank R. Cook Company** (first reported in M/R, Aug. 24).

Beginning in late 1958, Cook began a study and analysis of auxiliary power sources on the *Atlas* missile. A summary of the results is provided in the accompanying table comparing hot-gas APS versus battery APS..

In addition to this disheartening conclusion ($23 million had already been spent on the hot-gas APS program by **Convair-Astronautics),** there was no reason to expect that improved design might substantially brighten the picture. With the *Atlas* scheduled to become operational in September, 1959, development—for all practical purposes—was completed. This meant that the existing reliability of the hot-gas APS system was a "frozen" actuality. Production design units were in the process of being fabricated for use in the first operational missiles. Tight scheduling and a limited production capability, in addition to the obvious high cost, thus prevented the authorization of any major design changes.

The report also indicated that, even though many millions of dollars had been spent on the hot-gas APS program, no design effort ever had been authorized for a parallel battery-APS program.

According to company president Frank R. Cook, a weak effort had been made to produce a "breadboard" battery system for comparative purposes. Yet, said Cook, even though the comparison was an unreasonable venture, the battery system's inherent reliability was apparent.

Based on its three-year experience period with the *Atlas* program, the Cook report revealed that the following advantages would be effected through a battery APS system:

- 10:1 improvement reliability;
- 2:1 reduction in weight;
- 4:1 reduction in unit cost;
- 50:1 reduction in sustaining costs (maintenance, logistic support, spares, etc.);
- elimination of extensive maintenance;
- elimination of specially trained personnel requirements;
- 30:1 reduction in activation time;
- 10:1 reduction in remove-replace-verify time;
- 100:1 reduction in spares requirements; and
- elimination of contractor depot requirements.

Cook has stated that in its experience where ever comparison has been made between the two systems, hardware for the battery-type missile APS has proved to be lighter in weight.

Further, all of these advantages would be obtained without the sacrifice of any of the existing performance requirements.

Following a review of the Cook report (dated July 31, 1959) by the Air Force's Ballistic Missile Division and Ballistic Missile Office, the hot-gas APS program was cancelled for both the *Atlas* and *Titan* missiles.

The company noted also that besides the units it is providing now for all eight of the *Atlas* type batteries, it produces units for four battery types in *Polaris* and two for *Minuteman.*

Comparative Data (Atlas)

WESCON Show Emphasizes Design

by Frank McGuire

SAN FRANCISCO—A major Space Age accomplishment ran slightly afoul of human factors at the 1959 WESCON Show here, and made a mildly frustrating failure of efforts to open the show with an appropriate bang.

With the *Explorer VI* satellite orbiting high over South Africa, the Jodrell Bank radio telescope facility in Great Britain sent a command signal to begin transmission of stored telemetry data. The received signal was to be used in the official WESCON opening ceremonies. A loud and clear signal was received by Jodrell Bank and sent to **Space Technology Laboratories** in Los Angeles, which in turn relayed it to San Francisco.

However, the story goes that a young lady in the downtown office of the teletype company pulled the wrong plug and so the signal did not get from downtown San Francisco to the WESCON show at the Cow Palace.

It was a good show anyway.

• **Vast exhibition**—New products reigned supreme, and great emphasis was placed on design appearances of equipment. Exhibits by 37 young future engineers displayed equipment like plasma arcs, electron accelerators, and parametric amplifiers. Just about 1000 industrial exhibitors filled the huge Cow Palace with every type of electronic equipment that was imaginable —and some that wasn't.

Technical sessions, held every day of the four-day meet, covered things like reliability, antennas, ultrasonics, computers, semiconductors, vacuum tubes, component parts and production techniques, circuit theory, propagation, engineering management, nuclear science, and even medical electronics.

Miniaturization, sub-miniaturization and microminiaturization occupied a major spot at the show; most manufacturers demonstrated that they are pushing the lightness and compactness of their equipment, while still maintaining high performance.

An indication of this trend was seen in the 10-ounce, 14-channel tape recorder developed by **Leach Corp.** for airborne applications. This unit surpasses Leach's previous world's-smallest tape recorder by a considerable margin.

• **Throw-away on the way?**—In the reliability field, but still related to unit design—one of the more significant developments at the meeting was a paper by R. O. Stone of the National Bureau of Standards in Washington, D.C.

Stone pointed out that design trends like printed circuits, miniaturization, encapsulization and modular construction are tending to make disposal-at-failure a policy to think about. It has been generally assumed that this would be a prohibitively expensive method, but cost comparisons contained in Stone's paper show that this is not necessarily the case; throw-away modules of electronic equipment, instead of complicated, serviceable gear, may be on the way.

Another paper in this line, by N. L. Kreuder of **Burroughs Corp.,** cited the conflicting philosophies faced by the design engineer who is concerned with reliability: keep the duty of each part light, even though it means using more parts, and thus keep up reliability; or hold the number of parts to a minimum, even though some carry a greater load, and hope the low number of parts will maintain reliability.

Successful equipment has been designed under both theories, Kreuder said, but he cited a method for determining an optimum between them, so that a combination of the two methods would make for greater reliability than either philosophy alone.

• **Prize winners**—All in all, design considerations were heavily brought out in this year's show, and 18 awards based on industrial design were given to electronics firms—the first such competition sponsored by WESCON. The winners will be authorized to use an official label in connection with sales of the winning products.

Awards of excellence, based on "good design, equipment reliability, and how the products and their features are related to people," were given to **Ampex Corp.,** for a digital tape handler; **Hewlett-Packard,** for a clip-on DC current probe; **Cannon Electric Co.,** for an audio/electronic connector; **Electronics International Co.,** for a precision power oscillator; the **Digitran Co.,** for a switch; **Santa Anita Engineering Co.,** for its electropak system; and **ITT** for a closed circuit TV camera.

Awards of merit were given to: **Ampex Corp.,** three awards; **Autonetics; Electronic Associates** (two awards); **General Electric Co.** (two awards); **Librascope, Inc.; Tally Register Corp.;** and **Voltron Products.**

In the semiconductor area, a development by the Ceramics Technology Group at **Stanford Research Institute** promises to raise the temperature limits for transistor and diode operation from 400°F to 1800°F. The development, a new process for preparation of the devices, was carried out under subcontract from the Bureau of Ships and the **Shockley Transistor Corp.**

• **First for Schockley?**—The name Shockley also bounced into the semiconductor picture with a new "compensated avalanche diode" type consisting of a three-layered disk of silicon with extreme voltage-regulation precision. The unit, expected to go into full production in October, is designed for use in missile control systems and other applications. It was invented by the Shockley firm, where its principal developer was Dr. G. Smoot Horsley, assistant director.

A bit of a storm arose over the Shockley diode announcement: a number of firms cited similar devices that had come about as the result of production accidents in their plants. William Slusher of **Transitron Electronic Sales Corp.,** was quoted as complaining about the announcement's wording. "The Shockley organization has done an excellent job improving the dynamic resistance, but they do not have an extremely low temperature coefficient. To be useful as a voltage reference, the diode would have to be put in an oven," he said. Other companies voiced similar disgruntled feelings.

Texas Instruments showed a series of general purpose germanium transistors involving a glass-to-metal seal to allow use of automated equipment.

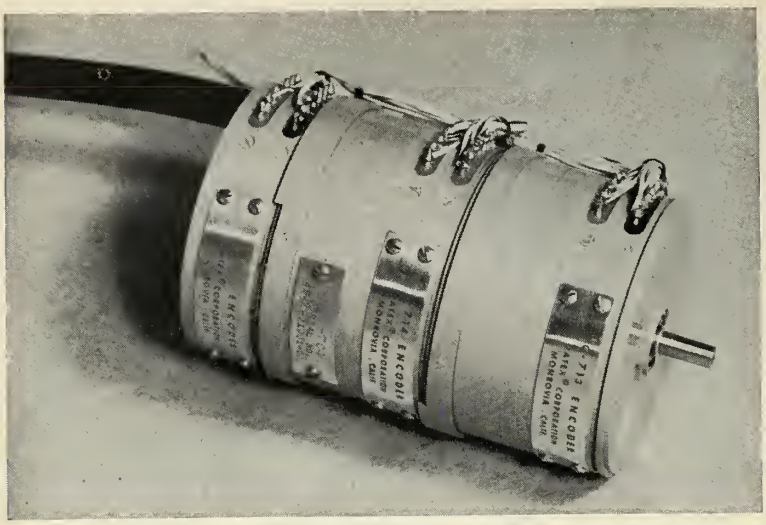
The Japanese electronics industry was well represented during the show, and received considerable attention. Various electronics equipment and components, including computer systems, were displayed by the Japanese. It was the only official foreign representation at WESCON.

EAGLE

symbol of a superior Navy

The United States Navy has traditionally been proud of its fighting men and superior weapons. The Eagle Missile System is a concept which will continue this tradition into the future.

The Eagle Missile System is an advanced long-range air-to-air weapon for fleet air defense and intercept missions. It is truly a second generation missile concept in which the performance is built into the missile itself rather than the carrier aircraft.



The Missileer will be the aircraft from which the long-range Eagle missiles are launched. This long-endurance aircraft will provide the ideal battle platform from which to carry out future aerial defense.

The Bendix Aviation Corporation, The Grumman Aircraft Engineering Corporation, Sanders Associates, Litton Industries, and the Westinghouse Air Arm Division are the key participants in the Eagle Program. The Bendix Systems Division has prime responsibility for systems management and engineering.

Better engineers and scientists interested in participating in such programs of the highest technical integrity are invited to write for further information.

Bendix Systems Division

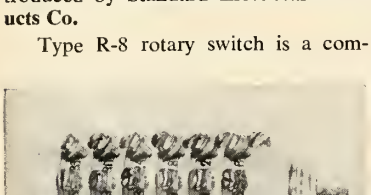
New Encoder Has 1 Million Positions

One million shaft positions can be resolved with the Model CG-704 Geared Encoder Assembly now available from **Datex Corp.** Designed for use where minimum size and weight are important, the assembly uses three Datex shaft position encoders and two gear boxes.

The encoder used on the input shaft provides 1000 positions of the least significant digit per 360° rotation. Because the disc of this encoder is coupled directed to the input shaft, accuracy is that of the encoder used (1 count).

This input unit is then geared 100:1 to a 100-position encoder. This 100-position encoder is, in turn, geared to a 10-position encoder. One hundred revolutions are required for full-scale output.

Because of the step-down gearing, the inertia reflected back into the driving system by the low-speed encoder is a fraction of the inertia of this disc and, therefore, has negligible effect on the drive requirements.



The CG-704 is 3″ in diameter, 5″ long (exclusive of shaft), and weighs less than 2 lbs. It will operate accurately at temperatures from +32° to +150°F and vibration up to 2000 cps under 8 g's.

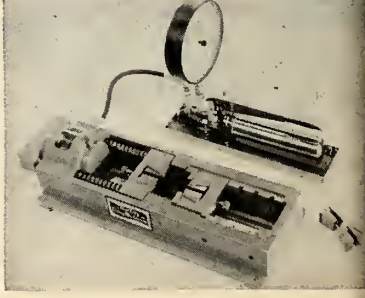
Datex Corp.
1037 So. Myrtle Ave.
Monrovia, Calif.

Rotary Switch Gives Circuit Design Flexibility

A rotary switch for missile and ground control equipment has been introduced by **Standard Electrical Products Co.**

Type R-8 rotary switch is a compact unit which is said to allow great flexibility in circuit design. Up to 48 separate circuits may be switched with a 6-section configuration. The switch employs a contract roller which is driven independently of the operating shaft at high speed making a fast break and make. Entire switching action takes place within the enclosure.

Other features include a contact rating at 28 VCD or 115 VAC; continuous 25 amp, resistive 25 amp, inductive 15 amp., overload 50 amp., and maximum switching per section; 1 pole—8 position—8 circuit, 2 pole—4 position—8 circuit.



Contacts are fine silver with coin silver contact bars. Bridging or non-bridging contact bars can be supplied. Action is positive on maintained positions. Stops or continuous rotation can be supplied as specified. Torque to operate the switch is 2 lb./in. which will vary with number of sections and other requirements.

Standard Electrical Products Co.,
Costa Mesa
Calif.

Tensile-Tester Produced For Portable Applications

A new family of portable tensile testers—for bench or wall mounting—has been developed by **Steel City Testing Machines, Inc.** These testers can perform standard tensile tests when mounted horizontally and can perform either tensile or compression tests when the tester is mounted vertically. A lower compression plate is available as an accessory when compression tests are anticipated.

Tensile load is applied to the test specimen by manually operating the hydraulic pump. The applied load is shown directly on the 8½″-diameter gage, which includes a maximum-indicating hand. Connection between the pump and the tester is through a flexible rubber hose so the maximum reading will not be affected by fracture reaction. Since the pump and gage unit must be bench mounted, the length

of the hose can be specified longer than the standard 18″ when the tester is to be mounted on the wall.

Base of the tester is cast aluminum to minimize weight while the jaws, cylinder, slotted ways and stop keys are steel to increase strength. The stationary jaw holder can be positioned in any one of three locations by shifting the positions of the stop key and the jaw holder.

Designated the PT series, these testers are available in two general sizes. Model PT-20 units have capaci-

ies from 5000 to 20,000 pounds. Details of these models are the same except that a 5000-pound gage is graduated in 25-pound increments and a 20,000 pound gage is graduated in 100-pound increments. Model PT-40 units have capacities in excess of 20,000 up to 40,000 pounds. A 40,000 pound gage is graduated in 200-pound increments.

Several sizes of flat and round jaws are available for specimens up to ½" in thickness or ¾". in diameter. All testers have a maximum stroke of 2½", and can take 11" long specimens for PT-20 units and 12" for PT-40's. Maximum width of specimens is 2".

For Model PT-20 units, tester base dimensions are 10 x 28" with a height of 6". For Model PT-40 units, tester bases dimensions are 11 x 31", with a height of 7". For all models, the pump and gage unit base dimensions are 5 x 21", with a height of 18". Net weight of Model PT-40 testers is about 145 pounds, with Model PT-20 testers being slightly lighter.

Detroit 26, Mich.

System Pumps Liquefied Gas Up to 12,000 psig

Dynamic Research, Inc., has a new automatic gas supply system that pumps liquefied gases at pressures up to 12,000 psig and stores the gas at room temperature after passing through a vaporizer. Higher pressures are available on request.

Model PLG-11-6 is a single cylinder, vertical pump complete with liquid nitrogen storage vessel and all controls necessary for automatic operation. It provides a continuous supply of regulated 6000 psig nitrogen gas at flow rates up to 5 standard cubic feet per minute. It supplies clean, dry gas automatically, with minimum power consumption.

The automatic gas supply system measures 30" x 36" x 22", weighs 400 lbs. dry and 450 lbs. filled, LN2. It comes in a cabinet mounted on casters for easy portability.

The new automatic gas supply—model PLG-11-6—was designed for lab testing, production line and ground support equipment.

Dynamic Research, Inc.
5701 Sepulveda Blvd.,
Los Angeles, Calif.

Circuit Equivalent Unit Has Flip-Flop Features

The first commercially available version of a "circuit equivalent" com-

ponent with characteristics comparable to a flip-flop or bistable multi-vibrator is the silicon trigistor (triggered bistable transistor). Developed by **Solid State Products, Inc.,** the trigistor is a silicon PNPN device with the unique property of triggered turn-off as well as triggered turn on control at its bases. It will turn on with the application of a low level positive pulse to its base.

Once on, the unit will remain on without the need for sustaining base current. A negative pulse to the base turns it off. It will then remain off until triggered on again. It is designed for operation in the range of 1 to 8 ma collector current. The trigistor is particularly useful for memory, counting, timing, gating, and logic functions.

The large board in the illustration is a two-transistor flip-flop circuit and the smaller board the trigistor equivalent.

Solid State Products, Inc.
One Pingree Street,
Salem, Mass.

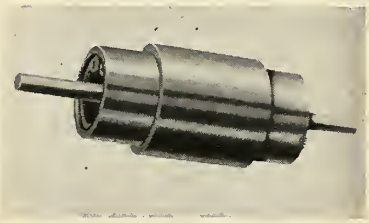
Crystal-Can Size Relays Have High Sensitivity

Electronics Division, **Elgin National Watch Co.,** announces three new types of Elgin-Advance relays that feature high sensitivity—of 250, 100 and 50 milliwatts—in a crystal can size with 0.2" grid spacing.

Nominal operating voltages range from 1 to 110 volts, with coil resistances from 35 to 10,000 ohms. Units measure only .875" high x .800" wide x .396" thick, and weigh only half an ounce.

Relays are rated up to 3 amperes resistive at 28 volts DC or 115 volts AC. They operate under vibration as high as 30 g's to 2000 cos., with shock ratings of 50 to 100 g's. The temperature range extends from −65°C to +125°C.

Designated MQA, MQB and MZC, these relays are hermetically sealed to withstand rugged environmental conditions and meet all applicable military specifications.



Units are DPDT (2 form C), and are designed for 0.1" grid printed circuits. Terminals are equally spaced in two rows at 0.2" apart, and are available with three-inch leads, solder hook, or plug-in terminals. All crystal can size mounting arrangements are available.

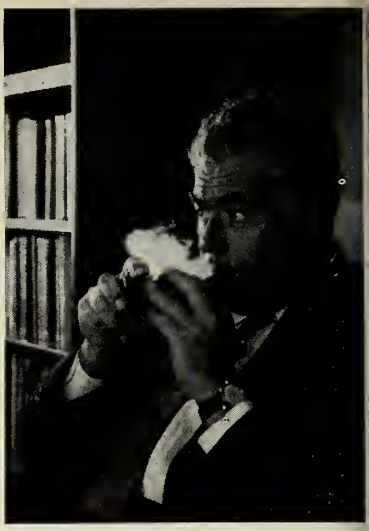
Electronics Div., Elgin National Watch Co.
2435 No. Naomi Street,
Burbank, Calif.

New Torque Transmitter Is Hermetically Sealed

Hoffman Electronics Corp. is now in production on a new hermetically sealed torque transmitter developed by the Electro-Mechanical Department of its Laboratories Division.

The torque transmitter is designed

to transmit rotary motion through a positive metal-to-metal seal by means of a flexible metal bellows. Electrical, mechanical and hydraulic controls, instruments, explosion-proof switches, and other apparatus requiring adjustment or control without disturbing hermetic sealing, may be regulated from outside a sealed area by using the new transmitter.



Weighing only .87 ounce, the transmitter is 2½" long and ¾" in diameter. It has a minimum life of 100,000 revolutions and an operating temperature range of −57° to 125°C. Input and output shafts are ball-bearing mounted to minimize friction. No gaskets or sliding seals are used.

Custom designed versions of the transmitter, with varying torque, pressure and backlash parameters, can also be provided to meet specific requirements.

Scientist Finds Space Answers on the Ground

Avco's Dr. Arthur Kantrowitz, a former Cornell professor, has led ICBM re-entry work, saving Air Force time and money

by Erica Karr

EVERETT, MASS.—The Air Force Ballistic Missile Division, which recently celebrated its fifth birthday, owes much of its "before-schedule" ICBM achievement to a brilliant scientist who brought space down to earth.

In the fall of 1954, while the fledgling outfit was wrestling with the unsolved re-entry heating problem, Dr. Arthur Kantrowitz, then professor of gas dynamics and engineering physics at Cornell University, proposed simulating re-entry conditions in the laboratory. At a Cornell cocktail party, the idea found a receptive ear in Victor Emanuel, Avco Corporation board chairman, who saw to it that Kantrowitz presented his proposal to the Air Force.

Although there was strong opposition, Lt. Gen. Bernard Schriever, then head of BMD, was quickly sold on using the shock tube technique to provide some comparatively fast answers to the re-entry heating problem. Today Dr. Kantrowitz heads the Avco Research Laboratory at Everett, Mass.

Recalling Kantrowitz's original presentation to BMD, Schriever has written: "His enthusiasm was immediately apparent when he ventured the opinion that he could produce the first answers in six months, since some of our advisors were suggesting four years as a more nearly correct time, while others questioned the application of the shock tube at all for such a purpose."

Kantrowitz with typical confidence proved his point at Avco's new research laboratory at Everett, which he had set up after being tapped for the job by Emanuel. "According to our contract," the scientist said, "we had to set up the lab, recruit personnel, build the apparatus, conduct the experiments and deliver the information within nine months."

At the end of six months he sent BMD the first data from shock tube measurements of stagnation point heating under re-entry conditions. Dr. Kantrowitz had developed a special shock tube over 100 feet long to simulate the re-entry heating environment. Gas is fired through the tube simulating flight speeds up to 18,000 miles per hour.

Because the shock tube did not allow materials testing for long enough periods, the lab later developed the arc wind tunnel, a device which uses electric arcs to heat air to extremely high temperatures.

The work on re-entry heating neared completion by the end of 1956. The two major questions which Kantrowitz and his staff answered to solve this problem were:

1) How much heat would be transferred to an object during re-entry at speeds up to 18,000 mph? And later,

2) What kind of materials stand up best under such conditions?

The answers:

1) Up to 10 kilowatts per square centimeter.

2) Ablating materials.

Avco also provided information on the effect of heat radiation to the reentering vehicle and the electrical properties of the gas which surrounds it.

The lab pioneered in the use of ablating materials for nose cones and under the direction of deputy director Mac C. Adams, has completed tests under simulated conditions to determine the properties of ideal materials. In conjunction with Avco's Research and Development Division at Wilmington, Mass., the Everett Lab confirmed its theoretical predictions and came up with Avcoite, an ablative said to be three times more effective than those with a plastic base. The arc wind tunnel was used in the tests proving out Avcoite. Avcoite coated the first nose cone to be successfully recovered after a full-range ICBM flight—the *Thor-Able*, April 8, 1959.

This phase of the lab's work is largely finished and Avco's recent $73-million Air Force contract for *Titan* nose cones attests to its success.

The subject taking up most of Dr. Kantrowitz's time at the lab these days is high- and low-temperature magneto-hydrodynamics which he has broken down into these areas:

- High temperature: exploring the properties of gases and shock waves in the million-degree temperature range with three goals in mind—(a) fusion reactor applications (b) understanding the nature of the Van Allen radiation belt (c) propulsion of space vehicles using nuclear or solar energy.
- Low temperature: studying the possibilities of generating electric power from gases less than 10,000°K heated by uranium fission.

For the military Avco has tackled the double-barrelled challenge of developing an ICBM nose cone for the Air Force that is invulnerable to attack while working with ARPA and the Army on their anti-ICBM program.

- **A poor start**—The road to international recognition as one of the

world's top scientists in the field of magnetohydrodynamics was a devious one at the start. Dr. Kantrowitz, who has won Fulbright and Guggenheim Fellowships to Cambridge and Manchester Universities, and one from the American Academy of Arts and Sciences, was thrown out of school at age 11 for poor work. Some choice items from the principal's letter to his mother on his expulsion: "whenever Arthur makes an effort to work, he bungles it . . . poor in following directions . . . poor attitude . . . can't seem to hold himself to a steady course—no improvement."

"Rates of development vary," Kantrowitz says of this episode in his life. "I didn't worry about it, but my parents sure did."

He did better in high school, still better at Columbia University where he majored in physics and where he collected his B.S., M.A., and Ph.D.

Kantrowitz, who takes his work seriously, but not himself, views his success matter of factly. Asked how he got into his field in the first place, he smiled. "If you're not clever or industrious, you have to move off into new areas." He found his area, he added, "by listening to and participating in the speculations of astro-physicists who are trying to put together an astronomical picture on the basis of meager knowledge."

• **Ground Floor**—Kantrowitz had his initial taste of aerodynamics on his first job out of school at NACA's Langley facility. "I was hired as a junior scientific aide in 1935 and for a week I did nothing but sort nuts and bolts. Then they apprenticed me to the wind tunnel mechanic and I was told in time I'd make a good wind tunnel mechanic."

By 1938, he and Eastman Jacobs, distinguished aerodynamicist, were deep in a project to build a stellerator-type fusion reactor; they tackled it "with delicious enthusiasm." A year-and-a-half's work later, they had worked up a terroidal-shaped model but they were unable to sell the idea as practicable. Although it was somewhat premature, its rejection was a bitter blow. Most of the actual physical facts on which modern fusion reactor speculations is based, were all known then.

In the years following, his work led to:

—invention of a variometer to measure the total energy a glider gets from thermal updraft. (1940)

—experimentation to develop an efficient supersonic compressor for turbojets (1943) which resulted in models that showed it was possible to get high compression ratios (1945).

—spadework in the development of shock tubes to study high-temperature gases (at Cornell-1947) with first published work on the method of obtaining very high temperatures by converging shock waves (1949).

"We learned to produce gases at 25,000°F and studied them, and when the country needed this kind of information for the re-entry problem technique, it was there and waiting," said Kantrowitz.

Fusion reaction is still a priority subject to Kantrowitz, and he delivered a paper on it at the Mid-August 10th International Conference on Ionization Phenomena in Sweden. "We now think we understand the mechanism of collision-free shock waves, which is one area that has to be understood before we can build a successful fusion reactor. We are trying to do fundamental experiments with the plasma conditions which must be faced in controlled fusion reactors."

Recently the Everett Lab has produced shock waves over one million miles an hour with an electric shock tube.

• **Food for thought**—The Everett Lab, employing a staff of 270, is situated on 50,000 square feet of what was formerly a warehouse in the Boston suburbs. Kantrowitz, who chose the site, said that he decided on the Boston area after a teaching stint at Harvard "because the atmosphere was intellectually stimulating."

Kantrowitz, only 45, has surrounded himself with a staff who look more like college seniors than scientists. All of them are in their late 20's and early 30's.

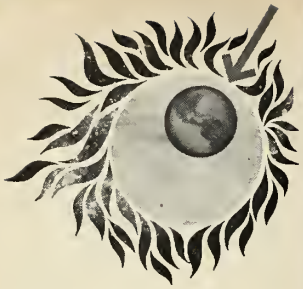
In setting up his laboratory, Kantrowitz felt it was time the old division of the classical disciplines—chemistry, physics, mechanics and aerodynamics—was halted. Calling on many of his former Cornell students, he established scientific committees in which problems are thrashed out from an integrated point of view.

His enthusiasm is infectious and has been cited by his co-workers as his most outstanding characteristic. Dr. Hans Bethe, one of the world's top physicists and member of the President's Scientific Advisory Committee, says Kantrowitz's enthusiasm runs the range from the purely scientific to space travel and is behind "the high efficiency of his laboratory."

According to Bethe, who worked with Kantrowitz at Cornell, he won't start on a project until he is entirely sure of the scientific basis, but his confidence runs high and "everything scientific comes easy to him. Recently he wanted one of the men in his laboratory to build a complicated scientific tool similar to one previously built by a much larger organization which had taken eight years to build the apparatus. So Kantrowitz told his collaborator he could take as much as three months to do it. The young man did it in three months, using a very different design from the large laboratory."

Another scientist who has watched Kantrowitz operate at close range seemed to sum it up when he said "If you have a difficult problem, call an expert. If you want the impossible, call Kantrowitz."

The Growth of Avco



Avco started in 1929 as The Aviation Corporation principally a holding company with interests in Roosevelt Field, Waco Aircraft, American Airways forerunner of American Airlines, as well as other aviation interests, and helped launch Pan American.

By 1937, under Victor Emanuel, who still heads the company, Avco had diversified and ended up controlling 45 companies, including Consolidated Vultee (later Convair), Lycoming, Stinson and New York Shipbuilding.

During the war Avco controlled an industrial complex that ranked third among the nation's producers of war materials. Its output ran from Willys jeeps to B-24 bombers. A policy change after the war switched Avco to civilian-market emphasis and it acquired Bendix and Crosley. Largely because of distribution problems, Avco sold Bendix to Philco in 1956 and shelved the civilian side of the Crosley operation, while holding on to the defense products end.

Avco had started backtracking into government work by the early 1950's and in 1954 laid plans for a basic research and technical facility to support the company's research and development activities.

The electronics research laboratory opposite Boston University was established in 1954 under the Crosley division; a year later Dr. Arthur Kantrowitz was assigned by Emanuel to set up the basic research laboratory which has concentrated on high-temperature gas dynamics and which came up with the answers needed to solve the re-entry heating problem. As a result of this work, Avco's Research and Advanced Development Laboratory won the contracts to design and build Titan *and* Minuteman *nose cones.*

And here's how you can release the brakes on your career.

DOUGLAS AIRCRAFT COMPANY
MISSILES AND SPACE SYSTEMS

has immediate openings in the following fields—

Electrical and Electronics:
Control System Analysis & Design
Antenna & Radome Design
Radar System Analysis and Design
Instrumentation
Equipment Installation
Test Procedures
Logic Design
Power System Design

Mechanical Engineering—
Analysis and Design of the following:
Servo Units
Hydraulic Power Systems
Air Conditioning Systems
Missile Launcher Systems
Propulsion Units and Systems
Auxiliary Power Supplies

Aeronautical Engineering:
Aerodynamic Design
Advanced Aerodynamic Study
Aerodynamic Heating
Structural Analysis
Strength Testing
Dynamic Analysis of Flutter and Vibration
Aeroelasticity
Design of Complex Structure
Trajectory Analysis
Space Mechanics
Welding
Metallurgy

Physics and Mathematics:
Experimental Thermodynamics
General Advanced Analysis in all fields

propulsion engineering . . .

By M/R STAFF

New fluorine compounds synthesis . . .
has been discovered at **Armour Research Foundation** by P. Y. Feng, operating under a contract from Air Force Office of Scientific Research. It is a radiation synthesis for preparing organic fluorine compounds. Patent applications have been made.

Basic research . . .
in chemistry, without any applications goals, led to the discovery, AFOSR officials say. Already, though, the synthesis has found a defense application: The Army is using it in munitions work at Picatinny Arsenal. Dr. Feng now has an Army contract calling for studies of radiation induced fluorination of nitro compounds. Dr. Feng's research contract with the Air Force OSR called for fundamental studies on the effect of radiation on organic compounds, and on the relationship between chemical structure and radiation chemical behavior.

New materials . . .
are expected to result from Feng's discoveries, AFOSR officials say. Already, the Air Force uses a wide variety of fluorocarbons as high- and low-temperature lubricants, gaskets, etc. The Feng discovery may result in even more materials—certainly should result in cheaper production. An AFOSR spokesman says: "The radiation induced synthesis is an excellent example of how basic research provides the scientist and engineer with the understanding and techniques necessary for the creation of new and improved materials."

Russian electrodeposition of alloys . . .
is described in a report to the Fourth Soviet Conference on Electrochemistry, Academy of Sciences of the USSR. R. F. Frantsevich-Zabludovskaia and A. I. Zaiats prepare alloys of molybdenum, tungsten, chromium, and titanium with iron, nickel and cobalt by dissolving the metals in ammino or oxyacido-ammino electrolytes and plating them out as solid solutions. The percentage composition of tungsten and molybdenum in the electro-deposit depends on whether the iron-group metal is iron, cobalt or nickel. It is highest with iron and lowest with nickel. The work was conducted in 1956, but the report was only recently made available.

Utilize beamed power two ways . . .
- Heat a propulsion fluid (e.g., hydrogen, ammonia, gasoline, water) which would then be expanded through a nozzle to produce trust.
- Convert it into electrical power for an ion or plasma rocket.

Lithium—new exotic fuel . . .
that's what the Pentagon is trying to say when spokesmen announce that the Defense Department will continue its studies on high-energy chemical fuels, despite cancellation of the many contracts associated with boron. Pentagon brass belatedly points out something that chemists have been screaming, unheeded, since all this talk about so-called exotic fuels started: boron is just one of many possibilities; some others are better. However, when the boron contracts were negotiated boron looked good, and lithium looked like it was going to be tied up almost exclusively in Atomic Energy Commission projects.

Lithium will get the green light . . .
as a fuel base for certain limited uses (kerosene-LOX will be used in about 99 out of a hundred situations) for several reasons:
- A large, established lithium industry is ready and waiting to provide all the metal that might be needed, and without further research and development.
- Lithium's chemical properties and at least one physical property —density—are much more favorable than are those of boron.
- Lithium and its compounds are easier to handle.
- Because of lithium perchlorate oxidizers, missile people already are geared to lithium procurement, handling, useage.

Air brake for a spaceliner

The earth's atmosphere, one of the biggest obstacles to getting into outer space, can be one of our biggest assets coming back. At Douglas we are investigating how we can use its braking effects on rockets returning from deep space trips at far faster than ICBM speeds. Success will allow us to increase payloads by reducing the weight of soft landing systems. This technique also will aid us in pinpointing landing areas. Current reports show real progress. Douglas is engaged in intensive research on every aspect of space planning, from environmental conditions on other planets to the destroyer-sized space ships necessary to get there. We invite qualified engineers and scientists to join us. Some of our immediate needs are listed in the column on the facing page. Please read it.

Arthur Shef, Chief, Advanced Design Section, Missiles and Space Systems, irons out a problem with Arthur E. Raymond, Senior Engineering Vice President of **DOUGLAS**

RELIABILITY

is what determines the success or failure of any weapon system at launch and during flight. Here at the Missile Division of North American Aviation, we are constantly striving to improve this most vital state of the art through analysis and evaluation of environmental criteria, system design analysis, statistical test programs, and other advanced reliability techniques. Engineers and statisticians with a minimum of five years full time related experience in aircraft or missile engineering will find this a most stimulating career in present and future efforts under development.

missile business . . .

By WILLIAM E. HOWARD

Worth noting marketwise in Dr. T. Keith Glennan's report to the Air Force missiles and space technology symposium are NASA's future spending plans. Major area for placement of contracts for the next year or two apparently will be in R&D. With a stringent money limitation evidently being imposed by the Budget Bureau, the hardware outlook isn't too bright.

Glennan makes the point—candidly . . .

"We are not nearly as far advanced in space technology as we had thought or hoped." And he adds: "In thrust capability, in guidance-injection, midcourse and terminal—in thrust control—in all of these areas there is much that must be learned and applied before we undertake the difficult missions we all talk about so glibly." He implies hot firings will be held to a minimum until the chances for success improve considerably.

At the moment Glennan feels "we have used up much of our missile technology" and this knowledge must be replenished by basic research. Accordingly, he says NASA expects to support "greater" research in universities and other non-profit institutions. In industry NASA will back both more basic research and advanced development of systems components.

NASA is drawing a bead on the moon . . .

Initial efforts of the civilian space agency are being concentrated on deep space and lunar missions, with shots aimed at near miss, orbiting and hard and soft landings of payloads. The main corollary objective is to develop reliability in rocket boosters. Comments Glennan: "It will be cheaper to waste payload space in using an oversize booster that becomes reliable through continued use than to tailor boosters for each specific mission with the attendant lowered reliability that surely will result from infrequent use." Right now NASA is leaning toward the **Rocketdyne** 1.5 million pound booster. It is spending $12 million in FY 1959 on this first stage engine for *Nova*—a deep space or lunar vehicle—and expects development costs eventually to run to $200 million.

The enormous expense of space exploration . . .

confronting the United States—if and when it decides to plunge ahead—was analyzed last week at the Commonwealth Spaceflight Symposium in London. Derek W. Morley, scientific writer for the London Financial Times, estimates the total cost of developing *Nova* for a manned lunar roundtrip will be $1 billion. And he says the multi-stage 2400-ton rocket may cost $40 million per shot with conventional fuels.

To assemble in orbit a manned laboratory weighing 75 tons, using *Nova* to do it, would cost around $2 billion, Morley estimates. His figures, incidentally, support economic arguments in favor of developing manned recoverable boosters that can be reused.

With the proposed Goodyear *Meteor* . . .

Morley says the total system cost of 30 expendable boosters would be $98 million against $150 million for the same number of recoverable boosters. But if 1000 flights were made over 5½ years, "the picture would change and the total system costs using recoverable boosters would be $523 million against $1.3 billion for a system using expendable boosters."

The financial correspondent is convinced . . .

space exploration is not outside Britain's means—if it rigorously selects projects. His idea is to gain experience with inexpensive space flights, ignore chemical fuels and concentrate on long-term R&D of nuclear rockets. And to make the price rock bottom, he suggests early concentration of development work "in the area where testing, final assembly and launching must be carried out—namely (the Woomera range) in Australia."

contracts

NASA

$380,000—Bell Aircraft Corp., for reaction controls for Project *Centaur*. (Subcontract from Convair/Astronautics Div. of General Dynamics Corp.)

MISCELLANEOUS

$485,345—Servomechanisms, Inc., for the production of true airspeed computers. (Subcontract from Lockheed Aircraft Corp.)
$300,000—MB Electronics Div. of Textron Electronics, Inc., for advanced electronics and electromechanical test equipment. (Subcontract from Aerojet-General Corp.)

NAVY

$8,000,000—General Electric Co., Defense Electronics Div., Utica, N.Y., for *Sidewinder* guidance control units.
$1,000,000—Baldwin Piano Co., for production of *Sidewinder* fuses.
$1,000,000—Minneapolis-Honeywell Regulator Co., for production of *Sidewinder* fuses.
$194,000—Diversified Builders, Inc., Paramount, Calif., for construction of *Polaris* static test complex facilities.
$9,800—King-Cowles & Associates, Inc. dba Robert W. King Construction Co., N. Hollywood, Calif., for construction of AEC launch complex.

AIR FORCE

Filton, Inc., Systems Div., for control of electromagnetic interference on the extreme altitude AMQ-15 Air Weather Reconnaissance System. (Amount not disclosed.)
$22,000,000—General Electric Company, for production of radar course directing groups.
$2,000,000—General Electric Co., Defense Electronics Div., Utica, N.Y., for transmitter sets, transmitter groups and ALT-6B ECM equipment.
$1,400,000—BJ Electronics, Borg-Warner Corp., for signal generators.
$739,772—Goodyear Aircraft Corp., Akron, Ohio, for repair and modification of AN/DPQ-4 ATRAN nose package components applicable to *TM-76* weapon system (Two contracts).
$724,680—Raytheon Manufacturing Co., Newton, Mass., for magnetron tubes.
$622,493—Tung-Sol Electric, Inc., Newark, N.Y., for various electron tubes.
$415,000—Raytheon Manufacturing Co., Waltham, Mass., for various electron tubes. (Two contracts.)
$400,000—Space Corporation of Dallas, Tex., for equipment to be used in the GAM-77 *Hound Dog* missile program. (Subcontract from North American Aviation.)
$270,000—The A. W. Cash Co., Decatur, Ill., for missile fueling control valves. (Subcontract from Blaw-Knox Co.)
$213,255—Radio Corporation of America, Electron Tube Division, for various electron tubes. (Three contracts.)
$161,100—Kuthe Laboratories, Inc., Newark, N.Y., for electron tubes.
$134,303—Aerojet-General Corp., Azusa, Calif., for rocket launching towers.
$102,000—Republic Aviation Corp., for trajectory studies of space probes plus an analysis of data handling techniques and guidance requirements for changing the orbit of a satellite.
$96,710—Henry Spen & Co., Inc., Brooklyn, N.Y., for cradel aircraft-missile components.
$94,372—Sylvania Electric Products, Inc., N.Y., for electron tubes.
$70,771—Dynatronics, Inc., Orlando, Fla., for research and development of two-channel airborne telemetry transmitters and transistorized encoders.
$41,049—University of Rochester, for basic research on the optical and electrical properties of solids. (Two contracts.)
$27,950—Metco Inc., Salem, Mass., for electron pressurized band pass transmitting receiver.

ARMY

$4,900,000—Aerojet-General Corp., for surveillance drone systems.
$2,486,125—John H. Sellen Construction Co., Seattle, for *Bomarc* IM-99B facilities.
$1,952,873—Lawless and Alford, Austin, Tex., for *Nike-Hercules* facilities.
$1,858,211—Beacon Construction Co. of Mass. Inc., for construction of *Nike-Hercules* facilities at Offutt AFB.
$1,674,830—Browning Construction Co., San Antonio, Tex., for *Nike-Hercules* facilities, Dyess AFB.
$1,512,525—Control Data Corp., Minneapolis, for a computer.
$1,314,271—Douglas Aircraft Co., Inc., for technical services.
$959,251—Southern Construction Co., Inc., Augusta, Ga., for *Nike-Hercules* facilities.
$878,433—Nichols Construction Co., Inc., Baton Rouge, La., for *Nike-Hercules* facilities.
$841,495—Consolidated Constructors, Inc., Portland, Maine, for construction of *GAM-77/GAM-72* facilities.
$254,879—Arthur Rabkin Construction Co., Inc., Cincinnati, for guided missile field maintenance shop.
$47,676—Penta Labs, Inc., Santa Barbara, Calif., for electron tubes.
$34,972—Ohio State University Research Foundation, for research and development, study and analysis of methods and techniques for measurement of temperature of the earth's atmosphere above 120,000 feet.
$30,130—Hamilton Standard Div., United Aircraft Corp., for solid-propellant spin motor system for *Little John* Phase II rocket.
$26,950—Raytheon Co., Microwave & Power Tube Division, for electron tubes.
$26,180—International Telephone & Telegraph Co., for electron tubes.

reviews

DIELECTRIC MATERIALS MOISTURE RESISTANCE STUDY: FINAL REPORT, J. J. Chapman and L. J. Frisco. The Johns Hopkins University for BuShips. Order PB 151014 from OTS, U.S. Department of Commerce, Washington 25, D.C. 76 pps. $2.

Polyethylene and polytetrafluoroethylene were virtually unaffected by the tropical exposure in these experiments to determine the degradative effects of moisture on 10 dielectric material specimens.

The two materials also showed excellent electrical properties during long periods of exposure to humid atmosphere. Other materials were polystyrene, monochlorotrifluoroethylene, polytetrafluoroethylene-glass laminate, glass silicone laminate, glass bonded mica, mica-filled melamine resin.

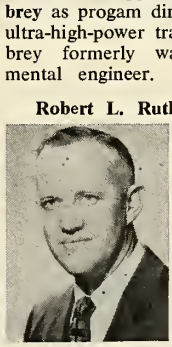
Most of the materials affected by moisture showed a deterioration of volume properties. In most cases, the degradative effects which were observed were attributed to moisture absorption. Specific effects are given for each material.

MICROPHONIC EFFECTS IN IMAGE ORTHICONS; R. K. H. Gebel, WADC. Order PB 151588 from OTS, U.S. Department of Commerce, Washington 25, D.C. $.50.

Experimental and theoretical investigations were conducted on image orthicon tubes to determine the cause and the best solution to the microphonic problem.

It was found possible to eliminate microphonics in these tubes electronically. However, the best solution to the problem can be obtained by careful design and construction of vibration-proof internal tube components.

people



HOEPPNER

Conrad H. Hoeppner, chief scientist of Radiation, Inc., has joined the editorial advisory board of Missiles and Rockets. Hoeppner holds a B.S.E.E. and M.S.-E.E. from the University of Wisconsin, did graduate work at M.I.T. and received his professional E.E. from the University of Wisconsin. He was formerly associated with U.S. Naval Research Laboratories, The Martin Co., Raytheon Manufacturing Co., General Electronic Laboratories, W. L. Maxon Corp. and Stavid Engineering Co. Besides holding more than 30 patents, Hoeppner has authored many technical papers.

CLARKE

Dr. Edward N. Clarke, has been appointed vice president for operations of National Semiconductor Corp. He was research physicist and section head for six years at Sylvania Electric Products and recently of Sperry Semiconductor Div., Sperry-Rand Corp. Dr. Clark has published numerous papers and holds several patents.

Pacific Semiconductors, Inc., has announced the appointment of **Frank Steinebrey** as progam director on an Air Force ultra-high-power transistor project. Steinebrey formerly was company developmental engineer.

RUTH

Robert L. Ruth, has been appointed chief engineer of the Marine and Ordnance Dept. of Vickers Inc. Prior to joining the company in 1958 Ruth was involved in development of hydraulic systems and submarine missile launching systems at Sargent Engineering Corp.

MULLIO

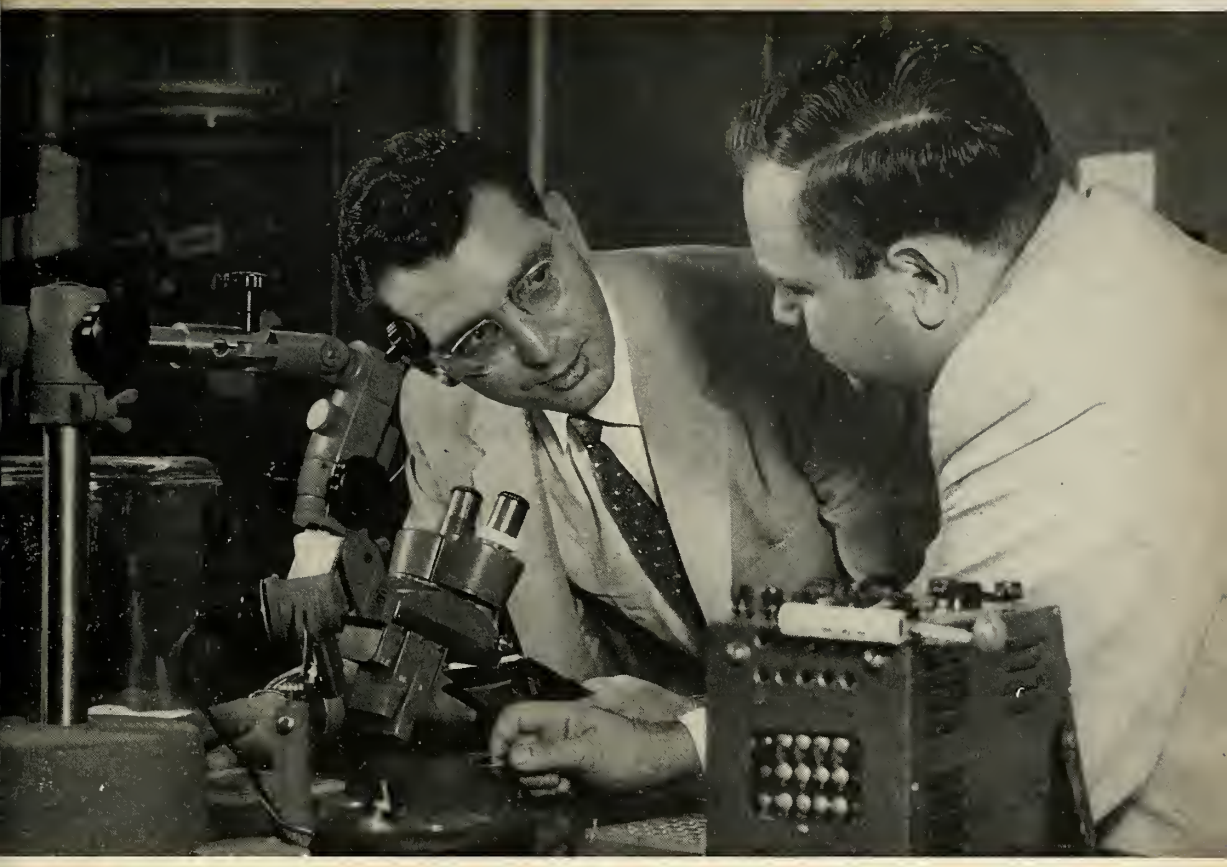
William A. Mullio has been named project manager for the development of a general purpose mechanical timer for missile fuzing and programming systems by Bulova Research and Development Laboratories, Inc. Before joining Bulova, he was with Sperry Gyroscope, Arma, and Control Instruments.

WHO READS MISSILES AND ROCKETS?

Well, for instance ... ENGINEERS AT WESTINGHOUSE DEFENSE PRODUCTS

Molecular electronics—a technological breakthrough at Westinghouse—is producing electronic systems *1,000 times smaller and lighter* than anything now in existence.

Through molecular electronics, drastic reduction in weight, size, power and heat dissipation requirements will permit space vehicles and satellites to perform a greater number and wider range of tasks. Greatest advantage is the vastly improved reliability achieved by the replacement of numerous components by a single solid state unit.



Recently, the Air Research and Development Command of the U. S. Air Force awarded a development contract to Westinghouse as a part of a broad program effort in this new electronic area. Experimental "hardware" is being fabricated by Westinghouse for infrared, reconnaissance, communications, telemetry, flight control and other military applications.

"Missiles and Rockets deals exclusively with astronautics. Spawned by aviation, missilery and outer space exploration today is an industry by itself." — George Shapiro (right), Fellow engineer of the Westinghouse Astronautics Institute, located at Air Arm Division.

"One company can't build the entire bird ... it takes thousands of parts and scores of companies. Missiles and Rockets keeps us informed of the products and capabilities of the other companies throughout the industry — a most definite aid in selecting contractors." — Harvey Saldin (right), Manager, power systems, Westinghouse Advanced Systems Planning group.

r. Gene Strull (right), Manager of the Semiconductor Divi-
n's Solid State Advanced Development Laboratory at the
estinghouse Air Arm Division, discusses molecular elec-
onics with Charlie LaFond of the editorial staff of Missiles
nd Rockets magazine. Westinghouse engineers have devel-
ed on a single semiconductor wafer, a system that performs all the functions of much larger conventional and transistorized electronic systems. Typical application is a tiny light sensing device for satellite telemetry less than ½" in diameter and 1/100th of an inch thick, one of several subsystems including pulse generators and multiple switches, already built and demonstrated by Westinghouse.

This fast-growing, dynamic industry (missiles and
tronautics) demands week-to-week technical and
ws coverage. Month-old news and developments
e of little use to today's engineer." — Jim Currie
eft), Radar Engineering Section Manager, Westing-
use Electronics Division.

WHY YOU SHOULD ADVERTISE IN MISSILES AND ROCKETS . . . Missiles and Rockets has *no waste* circulation—just those who manufacture missiles, space vehicles and allied equipment—and active Government and military personnel. *Over 29,000 missile technicians pay for their subscriptions to Missiles and Rockets*—the *best* circulation story among magazines covering the missile market. Missiles and Rockets reaches the thousands of companies, NASA and the Department of Defense who are purchasers in this multi-billion dollar market.

TELL YOUR PRODUCT OR CAPABILITY STORY THROUGH THE PAGES OF MISSILES AND ROCKETS—THE TECHNICAL/NEWS WEEKLY OF THE MISSILE/SPACE MARKET.

missiles and rockets

AN AMERICAN AVIATION PUBLICATION

1001 VERMONT AVENUE, N. W., WASHINGTON 5, D. C.

AFA Meeting to Attract 4000

MIAMI BEACH—*Titan,* the Air Force's second intercontinental ballistic missile, will headline a show of new weapons and industrial developments keyed to what has been billed as the second year of the Space Age. The first public display of *Titan* will be at the Air Force Association's annual convention to be held here from Sept. 2-6.

The big missile, manufactured at Denver by **Martin,** was being flown to Miami Beach at press time aboard a giant MATS C-133 turboprop cargo plane. It will be erected in front of the auditorium where the industry exhibits and most of the meetings will be held.

Convention plans thus far unwrapped indicate a program aimed at dispelling current confusion over buying policy and programs and the role that industry plays both in research and development and in procurement. There will be classified briefings for industry dealing with research and development. A procurement seminar will be open to all registrants.

The procurement seminar will be held Sept. 3. Moderator will be Gen. Edwin B. Rawlings (USAF, ret.), for six years the Air Materiel Command chief. Speakers include Donald R. Jackson, deputy secretary for procurement programs, and Lt. Gen. Mark E. Bradley, Jr., deputy chief of staff (materiel).

• **Guidance for industry**—AFA also has planned, with the cooperation of the Air Force, conferences between industrial representatives and the representatives of both AMC and ARDC. Their objective is to explain to individual companies what roles they may play in the ARDC picture and how they can find a place for themselves. In the case of procurement, AMC representatives will discuss individual problems as they relate to the weapon system philosophy. Specialists will answer questions relating to design, production and management. AFA said that these services will be available throughout the convention.

The overall Air Force story is to be told on Saturday, Sept. 5, in a panel discussion. Speakers include: Lt. Gen. William H. Tunner, Commander of MATS; Gen. Frank F. Everest, the new commander of the Tactical Air Command; Gen. Laurence S. Kuter, Commander of the North American Defense Command, who can be expected to discuss antiaircraft and antimissile missiles; and Gen. Curtis E. LeMay, vice-chief of the Air Staff.

Speaker at the annual Aerospace Banquet, Sept. 5, will be Gen. Thomas D. White, AF Chief of Staff. AF Secretary James H. Douglas will be the speaker at the annual awards luncheon on Saturday, Sept. 5.

Advanced registration at press time numbered 2600. A total of 4000 are expected to attend.

Venus Contact Will Be Tried—Minus Rockets

WASHINGTON—A NASA attempt to contact a rocket near the vicinity of Venus will be conducted next month—even though the rocket won't be there.

The program originally called for the Jodrell Bank radio telescope at Manchester, England, to track the two Venus probe vehicles—*Atlas Able* and *Thor Able IV*—which were to have been launched in June. The probes were cancelled when the payloads were not finished in time.

The telescope nevertheless will try to contact Venus at the time when the space vehicles should have arrived, when the planet is closer to earth than it will be again until January, 1961.

The Jodrell Bank team, headed by Prof. A. C. B. Lovell, hopes to learn more accurately how far Venus actually is from earth, how long it takes to spin on its own axis, and something about its cloud-shrouded atmosphere.

Mercury Escape System Won't Ignite Prematurely

WASHINGTON—NASA officials contended last week after the premature ignition of a Project *Mercury* capsule's escape system during a *Little Joe* test that "this could not happen" when man is put into the capsule atop an *Atlas* booster.

The escape rocket fired approximately 20 minutes before the vehicle was to be launched. The capsule's drogue chute opened, but the main chute failed to open as the capsule landed in the sea about 1000 feet from its Wallops Island launching pad.

Project *Mercury* scientists stated that the final capsule will have a more sophisticated electrical system than was used in the *Little Joe* test—"eliminating the possibility of a premature ignition."

No explanation was given for the main chute's failure to open. There were no injuries. The launch area had been cleared of all personnel some 10 minutes earlier. The *Little Joe* booster cluster of solid rockets remained on the launching pad.

House Group Questions DOD's Ban on Articles

WASHINGTON—The House Information Subcommittee is broadening its inquiry into the Pentagon ban on publication of Gen. Thomas S. Power's book on U.S. ICBM and bomber shortages.

The reason: The subcommittee has uncovered a recent general ban on the writing of signed articles by high-ranking officers for non-service publications.

Subcommittee Chairman John E. Moss (D-Calif.) has questioned the Defense Department's statutory authority for such a ban.

The subcommittee move followed an earlier inquiry into Defense Secretary Neil McElroy's banning of publication of SAC Commander Power's book "Design for Survival."

Power has repeatedly called for more ICBM's and bombers to keep U.S. deterrent strength from deteriorating. He is understood to have said in a preface to his book that it was a "report to our stockholders—some 175 million of them."

Moss disclosed that the military services were notified of the general ban in a recent memo signed by Chauncey Robbins, Deputy Assistant Defense Secretary for Public Affairs.

Lost *Discoverer* Capsules Have Scientists Puzzled

WASHINGTON—ARPA and Air Force scientists and engineers are still trying to solve the problem of their disappearing *Discoverer* recovery capsules.

Lockheed's *Discoverer VI* launched Aug. 19 from Vandenberg AFB—again performed perfectly up through the ejection of the capsule from the orbiting 1700-pound satellite over the Pacific. But again the capsule's radio went out and the capsule disappeared without a trace.

Discoverer V performed the same way only a few days earlier.

Both times C-119 cargo planes stood by, ready to attempt catching the capsules as they fell toward the Pacific. Ships stood by in the area near Hawaii to back them up.

Scientists feel the capsule may be burning up during re-entry—or else it's re-entering along an unexpected trajectory and ionization is blacking out the radio.

The failure to recover the 300-pound biomedical capsules is holding up plans to put more animals into orbit during the *Discoverer* series.

When animals are used again, they probably will be monkeys. Mice were used earlier.

——more about the missile week——

AIA Reports Need for Measurement Standards

American measurement capabilities are being seriously outdistanced by the requirements of fast-moving missile and space projects, according to a survey sponsored by Aerospace Industries Association. Results of the study made by **Sperry Gyroscope** has shown that a "measurement pinch" in the missile industry could threaten success of U.S. missile and space programs.

The problem uncovered by the AIA Quality Control Committee deals primarily with the increased need for extremely close tolerances and higher reliabilities. These requirements have forced introduction of a calibration program far beyond the needs of ten years ago. Today, missile components must be accurate to the millionth of an inch with proportionate standards in measurements of electronics, time, weight, temperature, pressure, shock, optics, and radiology.

The main purpose of the survey is to alert industry to the urgency of this measurement lack. The implication is that the National Bureau of Standards, with the support of industry, and sufficient financing can do the job. Consensus of the survey team is that this should not be the problem of NBS alone, however. Supporting work can be done by universities, industry research, and military calibration laboratories.

Air Force Air Material Command, for one, has already taken cognizance of the problem. Soon, the A.F. will have 163 centers equipped as precision measurement laboratories.

Second *Polaris* Sub Launching on Sept. 22

The Patrick Henry, sister ship of the George Washington nuclear-powered *Polaris* submarine, will be launched Sept. 22 at the **Electric Boat Division** of **General Dynamics Corp.,** Groton, Conn. The 380-foot, 5400-ton sub capable of launching 16 nuclear-tipped rounds will be ready for fleet duty in late 1960. The George Washington, first fleet ballistic missile sub, will be operational earlier next year.

Hot gas generator spin stabilization system weighing less than three pounds has been developed for *Polaris* missile by **The Garrett Corp.'s Airesearch Mfg. Co.** Generator incorporates an electric pyrotechnic ignition, time delay and composite base solid propellant in a single cartridge. Burning is at 1000 psi for .2 secs.

Industry Progress

Hazeltine Corp. heads up a team composed of **General Precision Laboratory, Radio Corporation of America, Sprague Electric Co.** and **Temco Aircraft** bidding on the Air Force's proposed airborne long range input (ALRI) system . . .AMC's Rome, N.Y., area has awarded **General Electric's Heavy Military Electronics Department** a $22 million contract for production of radar course directing groups . . . **Plastic Age Aircraft Corp.** and **Plastic Age Reinforced Products,** Saugus, Calif., are being merged into the **Plastic Age Mfg. Co.** . . . **Ling-Altec Electronics** has acquired all outstanding stock of **Consolidated Electronics Mfg. Co.** for $3.6 million.

Project *Mercury* procurement is shifting into high gear. **Chrysler** will provide eight Redstone-type missile boosters for the NASA vehicle that will put an American astronaut into orbit. **Waste King Corp.,** Los Angeles, has contract to manufacture gyro components for guidance system. And in a related area, **Chance Vought** is developing for Navy a space vehicle-type capsule for aircraft, utilizing shaped-charge explosive principle to separate cockpit section from remainder of aircraft.

Uses of gold and other precious metals for coating missile sections are increasing. **Engelhard Industries Inc.** reports gold is unequalled as a reflector of infrared. Company also is experimenting with platinum as a reflector.

Rocket engine generating about 15,000 pounds thrust was fired recently at Air Force's Arnold Engineering Center, Tullahoma, Tenn., in a wind tunnel at simulated altitude exceeding 100,000 feet. The ARDC installation said this marked the first time a rocket of its type and size had been tested under such extreme conditions.

WSMR Gets New Console

Complex communications and control console at White Sands Missile Range, N.M., has put the 4000-square-mile test center literally at the fingertips of the range operator. The new $150,000 console, with direct communications between all missile projects on the range, replaces outdated 6-year-old equipment.

AEROSPACE

ENGINEERS—SCIENTISTS

How about YOUR future?

Here's a company where the past and the present PROVE the future is interesting and worthwhile.

★ Leadership in Engineering Design
★ Leadership in Business Airplanes
★ Leadership in Ground Support Equipment
★ Diversified Production Contracts
★ Winner of Mach 3 Alert Pod Design
★ Diversity of Creative Opportunities
★ Winner of Mach 2 Missile-Target Award
★ Builder of Major Assemblies for Fighters
★ Stability of Engineering Employment
★ Expansion Programs Now in Process

BEECH AIRCRAFT has responsible positions open now for specialists in LONG RANGE programs on advanced super-sonic aircraft and missile-target projects in the following aerospace fields:

Human Factors
Analogue Computer
Reliability (Electrical)
Stress
Aero-Thermodynamicist (Heat Transfer)
Structures (Basic Loads)
Senior Weight
Dynamics (Flutter)
Systems (Missiles)
Electronic
Electro-Mechanical
Airframe Design

For more information about a company WITH A LONG RANGE FUTURE where your talents will build your own future—call collect or write today to D. E. BURLEIGH, Chief Administrative Engineer, or C. R. JONES, Employment Manager, Beech Aircraft Corporation, Wichita, Kansas. All expenses paid for interview trip.

NEWS OF ENGINEERING OPPORTUNITIES

OPEN ON MOST "TALKED ABOUT"

MISSILE OF THEM ALL

POLARIS

...and other diverse and complex weapons projects at General Electric's Ordnance Department in the Berkshires*

When the first operational Polaris missiles are installed in the "George Washington" —first atomic submarine specifically designed as floating platform for the Navy's undersea-launched IRBM s — it will be a day of great moment for the engineers and scientists at General Electric's Ordnance Department, who are now pouring their energies, imagination and technical skills into the development, design and production of Polaris Fire Control and Inertial Guidance Systems.

A day of celebration — but also one that ushers in new and other challenging problems — for the push to develop the next generation of long-range underwater ballistic missiles and kindred advanced weapons and weapon systems will be on.

There are openings now for engineers (*EEs or MEs*) with two to seven years' experience in these areas:

SYSTEMS DEVELOPMENT / SYSTEMS DESIGN OR EVALUATION
FIRE CONTROL ENGINEERING / INERTIAL COMPONENT DESIGN / COMPUTER DEVELOPMENT
ELECTRONIC CIRCUIT DEVELOPMENT / STRUCTURAL DESIGN AND VIBRATIONS
FIELD SERVICE & EVALUATION / QUALITY ASSURANCE & RELIABILITY ENGINEERING
ELECTRO-MECHANICAL DESIGN / ADVANCED PRODUCTION ENGINEERING
ELECTRICAL DISTRIBUTION SYSTEMS ENGINEERING / PLANT FACILITIES ENGINEERING
PRODUCT SERVICE INSTRUCTION / PRODUCT PLANNING / SALES ENGINEERING
CONTRACT ADMINISTRATION / TECHNICAL WRITING

Field Test Engineering (Florida, California and several naval stations in continental U.S.)
Also technician openings for graduates with missile experience

Write in strict confidence to: Mr. R. O'Brien, Dept. 73-WI
Ordnance Department of the Defense Electronics Division

GENERAL ELECTRIC

100 Plastics Avenue, Pittsfield, Mass.

Additional Projects Under Investigation at the Ordnance Department. Urgent, vital and engrossing as the Department's share in the Fleet Ballistic Missile Program is, it is just one of the diverse activities here that today offer engineers a progression of challenging assignments on: **Atlas Guidance Equipment • Talos Handling and Launching Equipment • Advanced Torpedo Development • Tartar Fire Control**

reviews

FREQUENCY RESPONSE FOR PROCESS CONTROL, Edited by William I. Caldwell, Geraldine A. Coon, and Leslie M. Zoss. McGraw-Hill Series in Control System Engineering. 400 pp. McGraw Hill, $11.50.

The book presents the fundamental methods of frequency response and their applications to the anaylsis, testing, and design of process control systems, along with an analysis of complete systems by means of highly effective techniques and typical solutions to many practical problems.

In a section devoted to theory, attentions is given to the distance-velocity lag, linear lag, and stability considerations. Methods of analysis are presented, with emphasis on the damped response method. The coverage of controller responses includes control charts for a variety of responses. Results are shown for variation of process and controller parameters. Closed-loop performances are explained, and disturbances are discussed with regard to their magnitude and location in the control loop.

ASBESTOS: ITS INDUSTRIAL APPLICATIONS, D. V. Rosato, Chief Engineer, Research Division, Plastics Plant, Raytheon Manufacturing Company, 214 p., $5.75, Reinhold Publishing Corp.

The book discusses various applications of asbestos, including its uses in the missile industry. It also serves as a guide to numerous industrial branches, including research and development groups, manufacturers, engineering schools, market research groups and sales management.

A census of asbestos products is included, along with reviews of asbestos materials available—asbestos cement, tile asbestos, heat and electrical insulation, asbestos friction materials, plastics, packings, gaskets, filters and others.

A MILITARY COLOR TELEVISION SYSTEM; R. K. H. Gebel, WADC. Order PB 151586 from OTS, U.S. Department of Commerce, Washington 25, D.C. $.50.

This pamphlet describes a color television system said to be superior for general military application and suitable for use with or without optical amplification.

The system, using a tri-color reproduction tube combined with either a two or three-color system, could be readily incorporated into a storage optical amplifier system. Field rate could then be changed without difficulty from one picture per second to 100 pictures per second.

The technical possibilities and limitations of color television systems are reviewed generally and the more important types of color systems are outlined, with emphasis on motion-detection limitation.

PERFORMING RESEARCH ON NEW APPROACHES TO PRINTED CIRCUITRY; Haloid Co., Rochester, N.Y. Order No. PB 135 502 from Library of Congress, Photo duplication Service, Publications Board Project, Washington 25, D.C. 27p. Microfilm $2.70, photocopy $4.80.

Performance tests have been carried out on vacuum evaporated chromium resistors and chemically deposited tin oxide resistors.

It was found that various overcoatings for higher temperature service and protection of ceramic-based components were tried unsuccessfully. Quantitative measurements of corona charging characteristics of materials for use in making electrostatic printing masters have also been made.

IMPREGNATION OF SILICON-CARBIDE ARTICLES WITH METALS; A. N. Novikov, translation of "Ogneupory" (USSR) No. 12, 1957. Order HB-4504 from Henry Brutcher, P.O. Box 157 Altadena, California. $6.60.

Gas-phase impregnation of silicon carbide articles with metals selected on the basis of the difference between their boiling point and the temperature of the active state of silicon carbide are prerequisites to successful impregnation.

Presented are details on an electric furnace used for gaseous impregnation of silicon carbide; methods of packing the impregnating materials; best composition of impregnating mix for ease of molding and performance.

Also in the translation are the experimental procedure and results; properties of silicon-impregnated silicon carbide; properties of various German and American silicon-carbide heating elements compared with those developed by the author between 1941 and 1956. The chief advantages of the new process are that workpieces may be air-dry and need not be recrystallized.

LITHIUM AND ITS ALLOYS; F. I. Shamrai, Translation of "Litiy i Ego Splavy," Moscow, 1952. Order AEC-tr-3436 from OTS, U.S. Dept. of Commerce, Washington 25, D.C. 230p. $3.

The contents include the general characteristics of lithium and its minerals, the chemistry of lithium compounds, the metallurgy of lithium, and its properties.

Also in the translation is material on the analytical chemistry of lithium and its binary and ternary alloys.

AN IMAGE ORTHICON WITH NARROW RANGE OF ELECTRON ENERGY IN THE SCANNING BEAM: R. K. H. Gebel, WADC. Order PB 151589 from OTS, U.S. Dept. of Commerce, Washington 25, D.C. 13pps. $.50.

A method of improving the low light level performance of image orthicon devices through basic design changes in tube geometry has been devised.

Electron-optical relationships for the scanning beam were developed and it was shown that for a scanning beam of narrow electron energy, the beam modulation factor can be made very low, improving the performance of the tube.

Another Threat to Our Space Program

For some time now there have been reports that Budget Director Maurice Stans could be expected to insist on heavy reductions in the Nation's missile and space program for Fiscal 1961-2. The speech which NASA's Dr. T. Keith Glennan made in Los Angeles on August 24 counseling a "go slow" program in space might appear to go along with this. Both could be considered to be obvious reflections of the Administration's attitude.

We suspect, however, that there may be a great deal of difference in how slowly Dr. Glennan wants to go as compared to how deeply Mr. Stans wants to cut.

The NASA administrator made several well-considered points: we have not advanced as far into the space field as we may think; our experience thus far has been less than satisfactory; there has been a lot of "glib talk" but there is still much, much to be learned before we advance farther than the short first step we have taken; reliability is our greatest problem; we lack manpower, facilities and funds to even begin all of the projects which have been recommended one way and another. Do we really believe, Dr. Glennan asked, that based on our past experiences, we have the skills to send a seven-stage probe to the moon for a soft landing and a safe return?

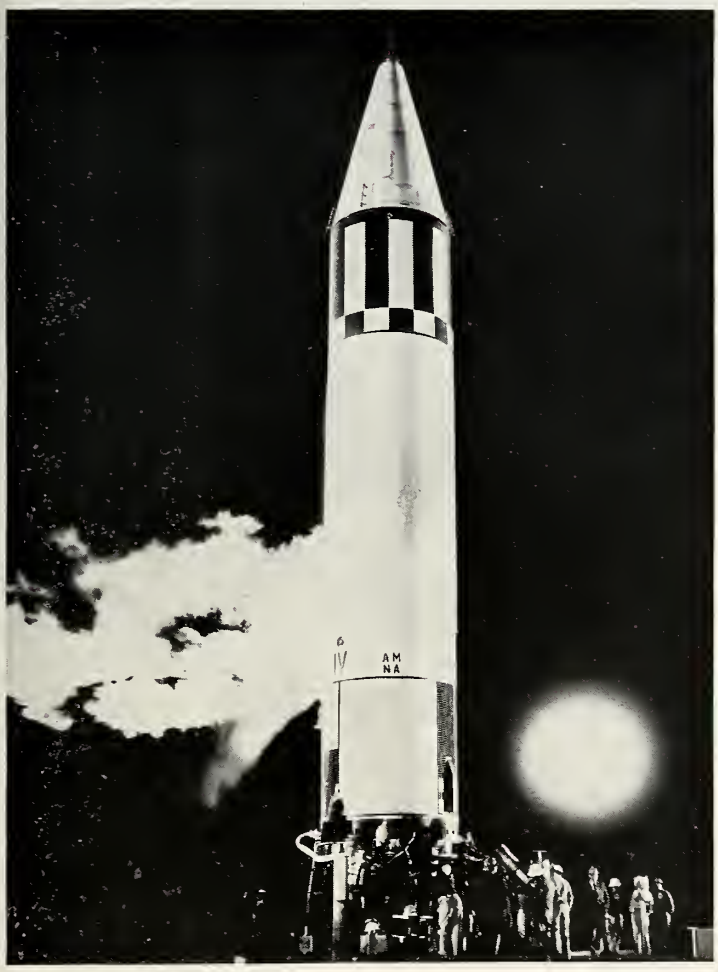
Mr. Stans, we have heard, would reduce or actually eliminate much of the current and projected military and civilian space program. *Nova,* the single chamber 1.5-million-pound-thrust engine under development by Rocketdyne, would be cut back to a theoretical research program. *Saturn,* the clustered engine of like power, would be curtailed. *Atlas* would be utilized as our basic booster as well as a major deterrent. Many of the current applied research projects in fuels and engines would be cut back or cut out.

We suspect that while there is some similarity in the tone of the two approaches, the point of interest may be quite different. We suspect that Dr. Glennan is interested and determined to produce a space program but wants to go about it sanely and reasonably. We suspect that Mr. Stans merely wants to reduce the budget.

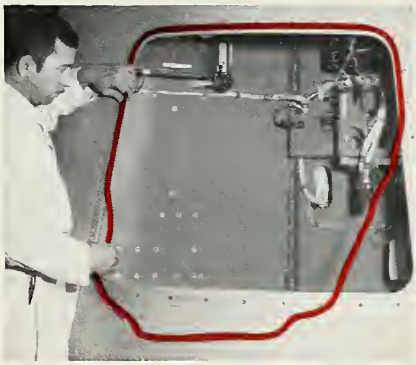
Fundamentally, it is difficult to agree with the Stans approach, if it is correctly reported, and difficult not to agree with Dr. Glennan. It is also difficult to understand how any reasonable official, in reviewing the events of the past three years, can doubt that this country must have a space program and must have the best available, commensurate with the progress of our skills. When Russia flew *Sputnik* we were hopelessly behind; money immediately became no object. Now, by calling on the bulk and best of our brainpower and technical skills—and millions of dollars—we have managed to catch up or at least come within striking distance of the Russians in the space field.

Do we now sit back because of a forthcoming national election or for any other reason, and lose the ground we have gained by such effort? Do we wait for another Russian achievement—the first rocket to the moon, the first man in space—to shock us back into action and to start another crash program?

We know that the business of the Bureau of the Budget's bargaining process is an annual exercise which begins about this time each autumn; that the services, with their billions, can take a cut and find room to maneuver. And we know, too, that Dr. Glennan will fight for the program he and the dedicated men who work with him feel is right for the country. But NASA has already lost $28 million from its small budget for this year and any further stringency cannot help but have a drastic effect on the space program.



There was one paragraph in Dr. Glennan's talk which didn't get much attention in the daily press, but we suspect it reflects the opinion of Congress and the people. It said:



"We are the one nation in this world which has developed its position of leadership through the application of science and technology to the alleviation of man's back-breaking burdens, while continuing to protect the right of the individual citizen. For us to play second fiddle to this space business is to admit that we have lost a part of our genius for experiment—for taking a competitive risk—for searching out new facts about nature that ultimately will improve the well-being of mankind everywhere. No, we cannot and I am sure we will not, fail to demonstrate that once again free men—when challenged—can rise to the heights and overcome the lead of those who build on the basis of the subjugation of the rights of the individual as they dictate to him the path he must take in response to the demands of the state."

CLARKE NEWLON

SILICONE NEWS from Dow Corning

Sealing Zero...and 500 F

Silastic was specified for the Jupiter's instrument compartment access door seal. The Silastic seal has better storage properties and can better stand high skin temperatures. Wire bundle clamps in the compartment also utilize Silastic.

In the cooling system for Jupiter's instrument compartment, low pressure liquid nitrogen vapor is carried by these ducts. Made of Silastic and glass cloth, they're light in weight, and are designed to meet specs of —75 to 600 F performance.

SILASTIC SILICONE RUBBER withstands storage, cold, re-entry

Chrysler Missile Division engineers specify Silastic®, the Dow Corning silicone rubber, for flexible ducting, access door seals, and other applications on the Army-developed Jupiter IRBM.

Why Silastic? In the first place, of course, because this material has excellent resistance to extremes of temperature. From below —130 to 500 F, it remains rubbery and flexible. Re-entry temperatures far exceed 600, but Silastic survives for the brief period of time involved, whereas conventional rubber wouldn't.

Also, Silastic resists the effects of storage and weathering. Sample parts have withstood 9 years weathering at Florida test stations without measurable change of properties. This is equivalent to over 26 years of exposure under average storage conditions. Other reasons why missile designers specify Silastic include resistance to moisture, ozone, corona, many fuels and chemicals.

For further data, write dept. 7620.

What is the Future for High Temperature Honeycomb?

Today his space travel is play. Tomorrow it is real. Many of the strong, light weight temperature resistant materials he will use will come from Swedlow. High temperature welded stainless steel honeycomb core is an important Swedlow contribution.

Today Swedlow core is found in the most advanced air and space vehicles. It is produced in many sizes, to exacting specifications, by new automatic processes. It is machined to close tolerances by new methods of electrolytic grinding. While serving industry's present needs, Swedlow's ambitious research program is exploring the future: developing methods for increased production, uses of new super-alloy materials, and techniques to broaden core applications.

The future will find Swedlow core in common use, wherever design requires high strength-to-weight and rigidity-to-weight ratios, plus high vibration damping, fatigue resistance and corrosion resistance.

Swedlow's technical service group will assist you. Call the Swedlow plant nearest you.

WRITE for technical bulletin "High Temperature Welded Honeycomb Core." Please refer to Dept. 21
